TAPPING A 7½ TON HEROULT FURNACE AT THE TIMKEN STEEL AND TUBE COMPANY

DECEMBER
1933

VOLUME 4 NUMBER 12

A *Guide*
TO BETTER PRODUCTS IN 1934

MANY manufacturers coming up for the third time after months of struggling with codes find themselves faced with an equally difficult problem—that of designing new products and re-designing old ones to fit the needs of 1934 markets.

To these manufacturers ENDURO says—"Here's a new metal with countless possibilities. Here's a metal that is corrosion-resistant and heat-resistant. Here's a metal that is always the same—that never changes—and upon which atmosphere, salt water, fruit juices and most chemicals have no effect. Here's a metal that to all practical intents and purposes is everlasting. Here is a metal that stimulates sales."

There's a place for one of the many grades of ENDURO in the products you will be marketing in 1934—automobile parts, electrical appliances, food handling equipment, chemical apparatus, soda fountains, bars, cocktail shakers, jewelry, brewery and distillery equipment, architectural decorations, oil refinery equipment, parts for high temperature furnaces, or whatever products you may make.

Work ENDURO into your next year's products and watch the sales-curve go up.

HIGHLIGHTS

by H. W. GILLETT

Are All Alloys Age-hardenable?

Most every alloy system seems to have some compositions that are age-hardenable when age-hardening is carefully looked for. Garre & Vollmert (page MA 378 L7) find that Ag, Sn or Cd allow it in Pb. Four Japanese authors (page MA 389 L6) find it in Ni, Si and Ni Cr steels. Sauvegot (page MA 389 L7) reports a secondary hardening in V steels due to precipitation of V_4C_3 by an age-hardening mechanism, while Matignin & Calvert (page MA 389 L9) discuss it in the Al Be system.

Titanium Chloride Treatment

This titanium chloride treatment for aluminum apparently only works in English for the Ski's [Broniewski & Smialowski (page MA 378 L5)] couldn't make it behave. Steinhäuser (page MA 392 R1), however, finds a mixture of $AlCl_3$ and NaCl to be effective.

Vacuum Melting

Bottenberg (page MA 392 R2) finds that vacuum melting cuts the oxygen content of mild steel from about 0.03% to below 0.01%, while nickel, melted in ordinary fashion had 0.41% but less than 0.01% on vacuum melting.

Accelerated Corrosion Test Gave Misleading Results

Jominy and Archer (page MA 387 R3) add another to the cases where an attempt at making an accelerated corrosion test gave misleading and incorrect results.

What Would You Expect?

Canadian Mines Dept. (page MA 378 L3) tests 14 lots of Monel bought on open market and find properties to be as stated in trade literature of producer. Why not? Trade literature has to be dependable these days, if it is to have any effect on the purchaser. The consumer soon learns which firms make "puffing" statements and which put out correct engineering dope.

DO YOU want to know what metallurgical engineers are saying, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Metals & Alloys hereby extends to you good wishes for a very Merry Christmas, and hopes that the coming year will bring you all the fulfillment of your strivings.

Supraconductivity

Supraconductivity, the drop of electrical resistance to almost nothing at temperatures approaching absolute zero, intrigues many physicists. Meissner (page MA 377 L8) lists 121 references on this subject. See also Dorfman (page MA 377 R3), McLennan & others (pages MA 377 R9 & MA 378 L2).

A Cadmium-Nickel Sandwich

Because cadmium plating itself is rather soft, Korte (page MA 386 L10) suggests sandwiching a coat of Ni between two coats of Cd.

Internal Stresses

Dietrich & Lehr, Hennig, and an anonymous writer (*Technische Blätter der deutschen Bergwerkszeitung*) all discuss methods of detecting internal stresses in structural parts. (page MA 384 R1, 3 and 9)

Cementation with Uranium or Zirconium

Laissus claims that high surface hardness can be obtained on steel, cast iron and some non-ferrous metals by cementation with uranium or zirconium (page MA 387 R5).

What! No Deoxidizers?

Perrin says he can make killed, piping steel by stirring it with a special slag high in Na_2O without use of deoxidizers. FeO is also said to be removed. (page MA 391 L7)

Absorption of Sulphur in Open Hearth

Absorption of sulphur from the open hearth furnace atmosphere is discussed by Eisenstecken, Schulz & Bierner (page MA 392 R5).

Cadmium in Zinc

Room temperature solubility of cadmium in zinc is less than 0.1% according to Straumanis (page MA 382 L3).

Inclusions as Corrosion Centers

Some inclusions in steel act as centers for corrosion, others don't, says Homer (page MA 380 R1).

Erichsen Tests

Krecek (page MA 384 L10) admits that the Erichsen test is not ideal but thinks it comes closest to evaluating deep drawing properties of all tests proposed.

Cutting Fluid Specs Obstacle

Fixed specifications for cutting fluids are considered by Geschelin (page MA 394 R10) as an obstacle rather than an advantage.

More Rare Metals

Rare metals are being studied, e.g. indium (Murray, page MA 377 R8), lanthanum, cerium, neodymium, yttrium, niobium, etc. (Quill, page MA 382 R 6).

Powdered Metal Bi-metal Strips

Carbonyl metal powder and iron powder, compressed in layers makes a good bi-metal strip, say Hamprecht & Schecht (page MA 377 R4).

Wire Drawing Lubrication

Lubrication in wire drawing is discussed by Macon (page MA 395 L3).

Sponge Iron

They are still working on sponge iron processes in Sweden, Norway, Canada, Germany and Russia according to several abstracts in Section 31 (page MA 401 R1).

HORSE HEAD 99.99+% UNIFORM QUALITY ZINC

FOR DIE CASTINGS

$ and SENSE in Pumps and Die Castings

This Wayne Pump caters to your convenience. If you want a dollar's worth of gasoline you get it. If you want five, ten, or fifteen gallons, you get that. Both the price and the quantity are automatically registered and strikingly visible. It's consumer appeal is sound and sensible. ¶ Another sensible thing about it from your dollar's standpoint is this. The simple and ingenious controlling mechanism and many other parts are Horse Head—*uniform quality*—Zinc Die Castings. These parts cost less to produce, due to the many advantages of the die casting process. . . The Horse Head Zinc alloys used insure their rugged life. ¶ Think of your product in terms of this pump—zinc die castings may be the low unit cost item solving your production needs.

Editorial Comment

H. W. GILLETT

The Things That Count

R. A. BULL

SOME technical and engineering journals comment editorially on the political and economic situations affecting the business prospects of the industries served by those journals. We have refrained, and expect to refrain, from commenting on these matters in respect to metallurgy, not because we have no convictions on them, but because we believe that field should be left to journals of another type than METALS & ALLOYS. One very good reason for avoiding such discussions in a monthly journal is that, in the interim between the writing and the publication of such comment, conditions may and usually do change so materially that we have an act from Uncle Tom's Cabin appearing amid the scenery for Romeo and Juliet.

In METALS & ALLOYS we seek to record provable scientific and technical facts whose application will make for metallurgical progress. Such facts do not depend upon time, place, public opinion or personal reactions, though the speed of their adoption may be influenced by personal factors. Any one can check up for himself whether what is stated about a new metallurgical product or process is correct, while the applicability of a theory of political economy depends entirely upon what people think at the place and time its application is attempted.

People in mass do not think the same in different eras, people of different ages do not think alike, and, in fact, no two individuals will react just alike to the same set of conditions. The country's views on prohibition have changed. Yesterday, the Constitution was universally sacred, today, some hold it as but a scrap of paper.

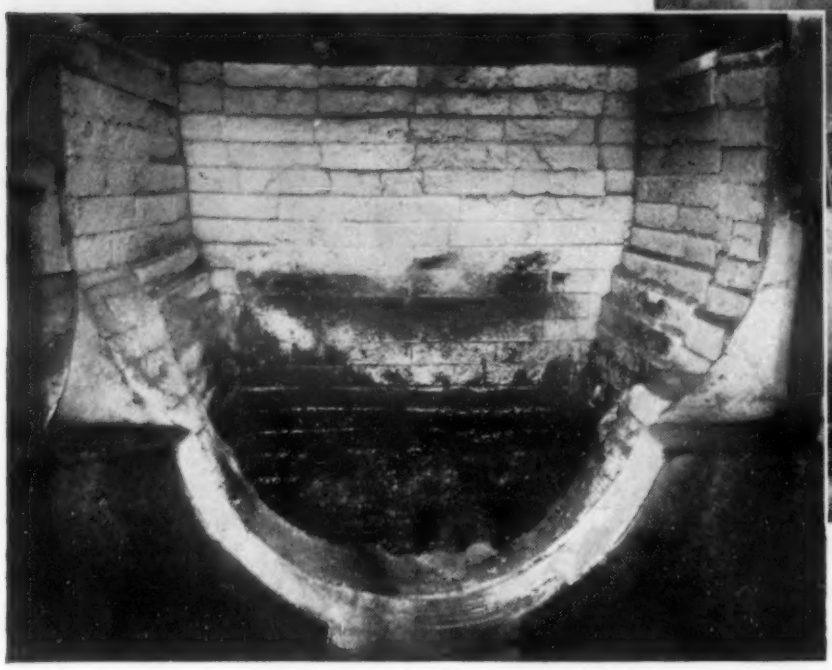
The metals with which we deal do act alike under the same set of conditions. If they do not appear to, we know that the trouble is that we have not yet separated and controlled all the variables.

Hence, metallurgy and the behavior of inanimate things in general are reproducible, while the behavior of humanity is not definitely reproducible nor predictable. Thus, we can confidently apply what we read in the *Archiv für Eisenhüttenwesen,* for example, to our own problems, but we cannot with equal certainty apply German experiences with inflation. History has a tendency to repeat itself, and one may feel that it would in such a case, but he can't prove that it would.

Even though wars and rumors of wars, politics and the doings of the government agencies of the day that we know chiefly by their initials, may occupy the front pages of the newspapers, is not the progress of mankind based as much on advances in science and technology as on changes in human thought? Did not Hall's winning of aluminum have as great an effect on the life of the nation as did the Boston Tea Party? Is not the development of stainless steel as important historically as the promulgation of the Monroe Doctrine? Will not future history be written from the pages of METALS & ALLOYS and its sister journals in metallurgical and other lines, at least as much as from those of the *Congressional Record?*

To pick names at random, which will have more effect on the welfare of posterity, the publications of Körber or the pronouncements of Hitler; the investigations of E. C. Bain, or the doings of General Johnson?

Public attention may be directed to what men think today, and that counts, but how things react also counts. When the tumult and the shouting die, it will be found that permanent, provable technical advances are the things that in the long run bring mankind a higher standard of living. So we prefer to devote the space in METALS & ALLOYS to the recording in our particular field of those things that will count in the long run, of the engineering facts that are applicable both today and tomorrow.—H. W. GILLETT



Technical Phraseology

PROBABLY most of those who read METALS & ALLOYS remember the three-fold injunction which somebody in the pre-tavern days cleverly phrased for the much-to-be-desired guidance of public speakers: "Have something to say. Say it. Stop talking."

Of course the application is good for those who write as well as for those who orate. Also of course, the admonition should be observed by writers on technical subjects. The command to "say it" implies the use of language that cannot be misunderstood, whether or not infinitives are split, and whether or not newly coined self-indicative words are employed. Carrying the idea further, it will perhaps be admitted that an important obligation resting on technical writers is that of conforming to usage recommended with apparent logic by officially constituted groups of qualified men, in terminology developed to clarify technical literature.

Some years ago, recognizing a serious need for the effort, the American Society for Testing Materials, the American Society for Steel Treating, and the Society of Automotive Engineers formed a joint committee to define heat treatment terms. It was a committee of highly competent, nationally known metallurgists. After wrestling with the problem of terms to distinguish between furnace cooling and air cooling, the decision, confirmed by tentative adoption by the A.S.T.M. as far back as 1927, was to include normalizing (distinctively associated

(Continued on Page 192)

Still another application proves the Economy of CARBOFRAX

REG. U.S. PAT. OFF.

AT the Ballwood Division of the Midwest Piping and Supply Company Inc., they use coke-fired furnaces for heating large pipe and flanges to a welding temperature. Ordinary fire clay brick in the fuel zone lasted but a week even with daily patching.

They installed "Carbofrax"—the Carborundum Brand Silicon Carbide Brick and now they get three month's life with one or two patchings of the front wall during that period.

Despite the operation under heavy blast, there is no slagging trouble as previously encountered; and "Carbofrax" withstands the severe abrasive effect of the pipe and flanges revolving in the coke bed.

They get cleaner welds with "Carbofrax" linings—there is a distinct saving in brick costs—in longer continued furnace operation—in labor costs.

Just another case where "Carbofrax" proves its economy.

Where higher first costs are not to be considered when the service rendered more than justifies it.

Electric Furnace
REFRACTORIES
in the Brass Foundry

This paper is submitted to the foundry industry as an official report of the Committee on Non-Ferrous Survey, a sub-committee of the Joint Committee on Foundry Refractories. The data given have been collected and summarized by members of the Committee and the results have been reviewed and approved by its chairman.

The original plan was to devote the investigation and report exclusively to the arc type of furnace. It was later thought advisable to include all brass foundry electric furnaces and every effort was made to obtain the fullest possible information with respect to all furnace types. The bulk of the information furnished by the foundries deals with the arc type of furnace and consequently this type can be and is discussed more fully than other types in the report. The work of the committee has to do exclusively with foundries and consequently this report does not include data from rolling-mill casting shops where the largest proportion of induction-type furnaces is employed. It is not intended that any comparison should be made between furnace types. That would be outside the scope of this committee's work and, in any case, such a comparison would have to include many factors which are not even mentioned in this paper.

The preparation of such a report as this necessarily involves a comparison between different plants as to their practice and their degree of success in carrying out certain operations. In making such a comparison there is always danger of seeming to be unpleasantly critical. To altogether avoid comparisons and contrasts would be to defeat the object of the work. Great care has been taken to emphasize the salient features of the investigation and to draw appropriate conclusions without making use of phraseology which might cause resentment on the part of anyone. Of course, the identity of individual plants cited is not disclosed although some might be recognized from the nature or magnitude of their operations. In any event it is hoped that the value of the information given will amply justify the manner of its giving.

H. M. St. John, Chairman,
Committee on Non-Ferrous Survey

As a subcommittee of the Joint Committee on Foundry Refractories it is the function of the Committee on Non-Ferrous Survey to collect and disseminate information regarding refractory practice and performance in non-ferrous foundries, in order that the industry may be kept fully informed as to progress made and results obtained by actual users of refractories. The following reports have already been published.

"Preliminary Report of Subcommittee on Survey of the Non-Ferrous Foundry Industry." American Foundrymen's Association, 1926.

"Refractories for Brass Foundry Furnaces." American Foundrymen's Association, 1928.

"Refractory-Maintenance Cements in the Non-Ferrous Foundry." American Foundrymen's Association, 1930.

"Care and Maintenance of Fuel-Fired Furnace Linings in the Non-Ferrous Foundry." American Foundrymen's Association, 1930.

The present report deals exclusively with the various types of electric furnace now in brass foundry use. Questionnaires were sent to all brass foundries known to be using any type of electric melting furnace. One hundred and sixty-five known foundry users of electric furnaces were canvassed, with follow-up letters going to the larger concerns not responding promptly in order that the report might be as representative as possible of the entire industry.

The following tabulation shows the scope of the melting operations covered by this report:

Number of questionnaires submitted	165
Replies received	84
Active reports received	63
Number of furnaces represented in active replies	167
Total average daily melting capacity of active responding concerns	780,000 lbs.

The electric furnaces in use by the responding concerns are as follows:

Detroit Rocking Indirect Arc— 53 concerns using 129 furnaces.	Repel-Arc— 2 concerns using 9 furnaces.
Ajax-Wyatt Induction— 7 concerns using 26 furnaces.	Baily Resistance— 1 concern using 3 furnaces.

The questionnaire is reproduced here in order to show the type of information sought and to assist in discussing the nature of replies received:

Questionnaire
on
Electric Furnace Lining Performance
submitted to
Sand Casting Brass Foundries
using
Electric Melting Furnaces

(1) Will you indicate the approximate size of your foundry expressed in pounds of metal per day of normal average melting capacity?

(2) What kind of electric melting furnace do you use? How many of each kind and size? Please state KW rating and charging capacity of each type and size.

(3) How many hours a day do you run your furnaces and about how much metal do you take from each? Number of heats or total pounds for each type and size?

(4) What is the approximate chemical analysis of the various alloys you melt? Approximate amounts of each melted per day?

(5) At about what temperature does the metal leave the furnace? State temperature for each alloy.

Nature of refractory. Amt. of insulation	Patching material used	Method of patching	No. of heats per lining before replacement	Method and time of seasoning a new lining	Method of washing or glazing a new lining	Part of lining requiring most frequent patching	Refractory cost
High alumina firebrick. 1″ insulation	Grade A. Elec. fce. patch	Use a high alumina wash	2800-2900	Slow wood fire 12 hrs. Follow mfrs. instructions	Alumina wash. Thick cream consistency	Around door, spout, top and sides	No record
High alumina firebrick	Fireclay patch	No attempt to patch small holes	300	Charcoal and coke. Arc 120 and 200 kw. hrs. 2 days	Cement wash	Port holes. Pouring area	No record
High alumina firebrick	Sillimanite	Inspected each day. Patched as required	1100 to date. In perfect condition	Mfrs. instructions	Glazed with molten glass after patching with Sillimanite	Roof, door and spout	$1.75/ton material and labor
High alumina firebrick	Aluminous oxide material		3000-4000	Intermittent arc application	None	Top, just above door	No record
Standard firebrick shapes. 4½″ insulation	Fireclay patching preparation	Thin coating weekly. Patching after 400 heats	700-1134	Small gas flame. 24-36 hrs.	Coat with plastic cement	Crown	$126.00 total. Average 35c/ton
Preformed firebrick. ¾″ Sil-o-cel	Fireclay patching preparation	Cleaned and patched each morning	3500-4000	Air dry one day. Wood fire 10 hrs. Preheat with arc to cherry red heat	None	Center of circle	No record
High alumina firebrick. 4″ insulation	Sillimanite ramming mix	Air ram patches. Patch after 150 heats, thereafter weekly	Average 1400	48 hrs. preheat. Intermittent arc applied	Wash with slurry of Andalusite cement. Dry between applications	Hearth	Material and labor new lining—36c/ton. No patching cost figures
High alumina firebrick. 4½″ insulation	Sillimanite patch	Weekly patching. Use material dry as possible and ram hard	1000		Glaze with sand and lime mixture	Door jambs and lentel block	Material and labor—25c/ton
Sillimanite			1000	Mfrs. instructions	None	Ends	
High alumina firebrick. 1″ Sil-o-cel	Aluminous oxide material	Chip slag and key in patch. Patch weekly after second week	1100	Charcoal fire over night. Intermittent arc until cherry red	Thin wash coat of high alumina	Top	Patching material and labor — 27c/ton. New lining 33c. Total—60c/ton. Brass—92c/ton
Special patented crucible. 5″ Jersey fire-sand insulation	Crucible patch	Patch spout only. Crucible cannot be patched	400 brass, 175-200 Ni alloy	Wood fire over night	None	Spout	Material cost. Ni alloy—$2.00/ton
Firebrick. 4″ insulation	Carborundum fire sand and fire clay	Weekly patching	Walls and roof —1 year. Trough —4 months	48 hrs. power applied to reach 2300°F.	None	Door opening and piers	
	Prefired shapes		2200-3000 brass and bronze 1000 tons				
Firebrick	Carborundum fire clay mix	Patch after 200-300 heats	600	12-15 hrs. preheating	None	Roof	No information
Sillimanite. Ramming mix	Sillimanite	After 100 heats patch around door. After 400 heats patch ends	Average 700	Slow fire 24 hrs.	Have not found glazing beneficial	Around door opening	Material and labor —new lining $1.14/ton. Patching 73c/ton. Total $1.87/ton
Firebrick. 1″ insulation		Each A.M. after 100 heats	1500	Intermittent arc. 24 hrs.	High alumina	Above door	
800 lb. furnace. 4½″ insulation, 4½″ firebrick, 9″ straight end walls, circle high alumina	End walls fire brick or sillimanite. Circle high alumina brick or sillimanite. Silicon carbide cement around door	Sills and spouts patched with silicon carbide. Very little patching otherwise	1000/refrac. lining. 2000-3000 insulation. 200 lb. furnaces patched weekly with Sillimanite or Andalusite.	48 hrs. gas flame. Arc to operating temp. Held there 3 hrs. before charging	None	Sill and roof. Let roof brick burn down to 1″ thickness and then replace	19c labor, 63c material. Total 82c/ton
Furnace maker's materials only	Furnace maker's	Very little. Charging door only	Average 1200, 540 tons; max. 2900, 1325 tons	Coke fire 12 hrs.	None	Directly inside charging door	540 tons. 29c/ton. Total $155.00
High alumina firebrick	Calcined alumina 3500°F. high temp. cement	Patch very seldom	1200	Dry out over pit fire one month. Preheated 8 hrs.	Glass for glazing	Around spout and near electrodes	No data
Jersey refrac. 1½″ insulation	High temp. furnace patch	Usually each A.M.	500-600	Wood fire 12 hrs. Arc—10 hrs.	Molten glass 1 hr. before charging	Around door	New lining cost—material and labor 61c/ton. Patching labor 9c/ton
4½″ firebrick. 1″ insulation		Repair bad spots at once	2368	Wood fire 4 days. Intermittent arc	2 coats of thin laying mixture on new lining	Opposite door	
Diaspore firebrick. 4½″ insulation	Andalusite patch	Chip out slag, dovetail patch. Ram hard, dry slowly, fuse with arc after 50th heat	350	Wood fire 48 hrs. Intermittent arc 12 hrs. Three 24 hr. days for seasoning before charging	Andalusite wash. Glass glazing. Fused glass about weekly	End walls and door jambs	New lining $1.23/ton. Patching 87c/ton. Total $2.10/ton
Preformed 1″ insulation		Patch weekly after 100 heats	3600-3700	Charcoal fire over night. Int. arc 4 hrs. 48 hrs. total seasoning	Glass	Roof	Lining cost 16c/ton. No patching figures available.
High alumina firebrick	Andalusite patch	Patch daily	Approx. 1000	Charcoal 24 hrs.	None	Near spout	
	Silicon carbide	Usually at end of day	Lining life usually one year. 5 heats/day. Est. 450 tons	Gas or oil burner		Side walls	
High alumina firebrick lime, 25% fluorspar, 5% charcoal, 20% soda	Andalusite	Spout only. 3 times weekly ash, 20% iron ore)	650-750	Charcoal fire 24 hrs. Intermittent arc 5 hrs. Cherry red and charge	None	Spout	All material and labor including electrical energy insulation—40c/ton
High alumina firebrick	Silicon carbide and clay	Weekly	1600 @ 800 lbs., 1800 @ 400 lbs., 1600 @ 225 lbs.	Charcoal fire 48 hrs.	None		New lining cost, 800 lb. fce., 31c/ton; 400 lb. fce., 25c/ton; 225 lb. fce., 42c/ton. Est. patching cost, material and labor, 12c/ton

Nature of refractory. Amt. of insulation	Patching material used	Method of patching	No. of heats per lining before replacement	Method and time of seasoning a new lining	Method of washing or glazing a new lining	Part of lining requiring most frequent patching	Refractory cost
High alumina firebrick	Al oxide and Si carbide cements	Each A.M. slight patching	1450 each to date. These are original linings good for indefinite service	Wood fire. Glaze patches with arc	Wash on thin layer refractory		
High alumina firebrick	Silicon carbide and clay		1030	Intermittent arc	None	Door and spout	New lining—material and labor — 36c/ton. No cost on patch
High alumina		Patch every A.M.	2069	Wood fire over night	High alumina refractory wash	Door and spout	
High alumina	Andalusite	Weekly and when necessary	Over 2000	Manufacturer's directions	Wash with Alundum cement	End walls around electrodes	
High alumina	High alumina	Week-end patching	5000-5500	Intermittent arc 10 hrs.	Use Aloxite	Door section	New lining cost — material and labor. installation and burning in—11c/ton. No patching cost
High alumina	Andalusite mix	Patch weekly after second week. Andalusite	2500 average	Slow arc 2 hrs. Charge immediately	Silica sand	Roof	New lining cost — material and labor 13c/ton. Patching 29c /ton. Total 42c/ton
High alumina. 1¼" Sil-o-cel	Fireclay and crushed brick	Weekly. Spout twice a week	2000-2850	Intermittent arc	Glazed with refractory cement	Spout and roof	No exact figures but estimated 40-50c/ton
High alumina. 1" insulation	Andalusite mix	Weekly inspection and patching	1100-1300	Coke and charcoal. Intermittent arc	Silica sand and lime	Spout and port holes	New lining—material and labor 41c/ton. Maintenance 28c/ton. Total 69c/ton
High alumina	Special cement	Every Monday A.M. cold furnace. Remove loose pieces. Trowel into place. Fill cracks. Wash thoroughly thin mix	Average of 10 linings each. LF—1325, 331000 lbs.; LFA—697, 313000 lbs.; AA —915, 823000 lbs.	12 hrs. gas or charcoal fire. Arc cherry red	Wash with high temperature cement	Roof	Material and labor. New lining LF 38c, LFA 51c, AA 40c. Patching LF 40c, LFA 40c, AA 50c/ ton. Total LF 78c, LFA 91c, AA 90c
High alumina	Plastic fire clay and Andalusite	Weekly	175 kw.—1200 125 kw.—2500 400 kw.—800	Manufacturer's instructions	Andalusite wash	Electrode section, door and roof	Average 32½c/ton of melt
High alumina	Andalusite	Chip out slag. Drive patch in hard and dry. Hold above 2300°F.—10 min.	1200-1500	10 hr. wood fire. Intermittent arc	None	Spout	62½c/ton. New lining installed plus patching material
Preformed high alumina set with chrome ore cement	None		Aver. 1700. Range 941—2163	Air dry for periods up to 6 months. 8 hrs. gas torch	None		55c/ton
Ganister bottom. 9" key brick	Plastic fire clay	Holes are patched as they develop. Top row or two of brick are replaced periodically	500	Line over the week-end. Charcoal fire. Melt Monday A.M.	None	Top or cover. 30-40 key brick once during the life of lining	
High alumina	Andalusite		1000-1500	Manufacturer's instructions	Glass or silica sand	Electrode ports and spout	
High alumina	Special cement	Start patching after 400-500 heats	Aver. 6600 on bronze. Monel—2000			Pouring spout	Patching — 20c/ton. Lining 6c/ton. Total 26c/ton
Mullite brick	Mixture ganister Si carbide and high alumina cement	Week-end patching cut slag-key patch. Wood fire wash with aluminous oxide material	2300-2400	Intermittent arc	Wash well with aluminous oxide material	"Breast"	Patching material $1.00, labor 60c, linings 56c. Total $2.16
High alumina	Special cement		Over 2500. Original lining remains in perfect condition	Life of lining is indefinite. Maintained constantly in perfect condition			
High alumina	Aluminum oxide cement	Daily inspection. Weekly chip-out and patch. Weekly wash	6727 each to date. Still O.K.	Wash lining with refractory cement and stand over night	Preheat. Melt broken glass	Roof	$1.08/ton total
Special brick	Andalusite		1000-1100	Wood fire over night. Intermittent arc	None	Spout and door section	94c/ton 350 lb. furnace. $1.23/ton 200 lb. furnace
Andalusite	Andalusite				Molten glass	Roof	
High alumina	Plastic fire clay and Si carbide cement	Every week-end	One year. 4500-5000 and over	Spare shell lining dried out by hot electrode between heats of furnace in service	Andalusite cement	Roof	No data
High alumina	Andalusite	Patch cold furnace when needed	All original linings still operating. Al—over 500, brass—over 1450, iron—over 800	Manufacturer's instructions	Glass in brass furnaces	Door section	No data (see lining life)
High alumina	Plastic fire clay and Andalusite	Patch daily as needed	1500-1800		Andalusite wash with sodium silicate	Door and spout	No data

63	100000 lbs.	17 Ajax-Wyatt 75 Kw.-1000 lb.	24 hrs.	1000 lbs./ heat	72-3-25 85-5-5-5	2000 2200	Light and medium Plumbing goods	Clean metal 20% dry turnings	Lime charcoal soda ash	Yes. Must be removed once each week

(6) Please state the general nature of the castings, indicating whether light, medium or heavy.

(7) Are the metal charges relatively clean or do they contain a good deal of non-metallic material? What proportion of turnings is used? Are the turnings wet or dry? If wet, do they contain oil or water and approximately how much?

(8) Do you use fluxes or covering slags? If so, what and how much?

(9) Do you have difficulty with the building up of slag in the melting chamber? If so, how do you remove this slag? Is it a serious problem? Do you take any special precautions to avoid this condition?

(10) What kind of brick or refractory materials do you use for furnace linings? In replying to this you may describe the type of material or give the name of the manufacturer and the grade, name or number which he assigns to it. Please state nature and thickness of insulating lining back of refractory.

(11) What patching material do you use? (If you use any of the special refractory cements, give the maker's name and the trade name or number which he gives to the cement.)

(12) Please describe your patching practice briefly. How soon do you start patching a new lining and how often do you patch?

(13) How many heats of metal do you get before the lining has to be entirely replaced?

(14) Describe briefly your method of preheating or seasoning a green lining, stating how much time you allow before charging.

(15) What method, if any, do you use for washing or glazing over a new lining before starting to melt?

(16) What part of the lining requires most frequent patching?

(17) Give what information you can regarding total refractory costs, including material and labor for original installation; also for patching (itemized if possible).

The active reports received are summarized here in tabulated form to facilitate rapid comparisons of results and analysis of the individual items of performance. See Table I.*

*Editor's Note: Table I is the extensive tabulation of the 63 Active Responses here attached.

BAILY RESISTANCE AND REPEL-ARC FURNACES

Since but one concern reported on the Baily and two concerns on the Repel-Arc furnaces, and in view of the diminishing use of furnaces of these types, only brief mention will be made of them.

The Baily furnace user, melting yellow brass and hardware bronze, stated that no cost data were available. A life of one year is reported for walls and roof while the trough is replaced every 4 months. Walls and roof are constructed of high grade fire brick of high alumina content while the trough is of a carborundum fire-sand mixture. Frequent trough replacement is doubtless a considerable item of expense in this unit and it is to be regretted that no cost figures were given.

One Repel-Arc user states that a special patented crucible is used which gives a life of 400 heats on red brass, resulting in a crucible cost of 92c per ton of brass. On nickel alloy, this same user obtains 175 to 200 heats at a crucible cost of $2.00 per ton of alloy melted.

The other Repel-Arc user melts red brass nine hours daily, using a rammed and brick lining. The bottom is of gannister, while the sidewalls are of 9 inch keybrick of first quality. 500 heats per lining are reported but no cost figures given.

ANALYSIS OF RESPONSES FROM AJAX-WYATT FURNACE USERS

Seven concerns have reported using a total of 26 furnaces. Six of these users operate 9 furnaces, 8-10 hours per day, while the seventh user has a battery of 17 furnaces, operating 24 hours per day. It is assumed in the latter case that the furnaces are not all in simultaneous operation, inasmuch as the total capacity is reported as 100,000 pounds per day.

These installations are used for the production of plumbing goods, valve castings, hardware and fixtures. Three concerns melt yellow brass exclusively, one of which reports 1200 heats per lining (pouring temperature 2150°F.), another 2500 heats (pouring temperature 1985°F.), while no information is given by the third as to lining life. In each case the refractories used are those of the furnace manufacturer.

Nature of refractory. Amt. of insulation	Patching material used	Method of patching	No. of heats per lining before replacement	Method and time of seasoning a new lining	Method of washing or glazing a new lining	Part of lining requiring most frequent patching	Refractory cost
Original lining high alumina	Ganister and fire clay mixture	Weekly and as needed	10000-12000. Lining lasts indefinitely. Maintained constantly in perfect condition				Material and labor. Total 28½c/ton
High alumina	Andalusite	Every 2 or 3 weeks. Chip clean. Key back. Drive hard. High heat	Have run original linings over 18 months. Still O.K.	Manufacturer's instructions	Andalusite rammed and washed over entire surface	Above the door. 4 hrs./furnace each 2 weeks	15c/ton. Total maintenance cost
High alumina	Andalusite	Inspection and patching on Saturday	1000 to date. Another 200 expected.	Manufacturer's instructions	Andalusite wash	Door section and roof	No figures but very minor expense
Furnace maker's special brick	No patching		2500	2 days electric with resistor. 1 day—gas flame	None		Not available
Furnace maker's lining	Special cement	Rarely	1200	72 hrs. dry with electric coil. Then oil torch 5 hrs.	None	None	88c/ton
High alumina firebrick. 4" insulation	Sillimanite patch	Weekly	Original lining. 1539 to date. O.K.	Manufacturer's instructions		Spout and end walls	
High alumina. 1" Sil-o-cel. 4" Sil-o-cel in 750 lb. furnace	High alumina cement	Patch weekly	350 lb.—1400 aver., 250 lb.—1000 aver.	Charcoal fire. Arc preheat. Line Saturday and melt Monday A.M.	None	Section over door and end walls	350 lb.—new lining —30c/ton. Doors 3c, patching 42c/ton. Total 75c/ton. 250 lb.—52c + 3c + 64c. Total $1.19
Special cement rammed in			Not stated				No data given
High alumina	Special cement	After 2 week operation — daily around spout	1600	Intermittent electric arc	None	Spout	Not available
High alumina	Special cement	Every second day	200		None	None	$3.57 new lining. 89c maintenance. Total $4.46/ton
High alumina originally. 1" insulation	Si carbide cement	Patched every night. Washed with Si carbide cement	26000-28000 on each of 3 furnaces. Life is indefinite	Wood and charcoal fire 4 hrs.	Wash with silicon carbide cement	Roof	Refractories and labor 28c/ton total
Mullite lining	None		500. 500,000 lbs. aver. production	Heated with gas burner	None	None	80c/ton

The largest foundry user of this type furnace melts both red and yellow brass—72-3-25 and 85-5-5-5 mixtures. It is not indicated what percentage of each constitutes the total melt. The refractory used in this case is a Mullite material and the melting schedule in 24 hours per day. An average production of 500,000 pounds (500 heats of 1000 pounds each) is obtained per lining, resulting in a refractory cost of 80c per ton.

The other three users of this type furnace report melting the following alloys:

Cu %	Sn %	Pb %	Zn %
85	2.5	1.50	11
76	3	3	18
81.5	3	7	8.5
84.0	3	3	10

As shown in Table II, cost figures were given in only 4 cases —29c per ton for one of the yellow brass installations which appears to be the cost of material only for new linings; 80c per ton in the case of the 24 hour per day installation, melting both

Table II. Data Reported by Ajax-Wyatt Furnace Users

Response Number	Alloys Melted	Linings Used	No. of heats Obtained	Tons Melted per Lining	Material Cost	Cost per ton of metal
18	Yellow brass 32% Zn	Ajax	1200	540	$155.00	$ .29
25	11 to 18% Zn	Ajax	1200	450		
39	Red brass 8-10% Zn	Preformed Prefired firebrick	1700	510		.55
55	Yellow brass 25% Zn	Ajax YB108	2500	1250		
56	Brass and Bronze	Ajax	1200	396		.88
59	Yellow brass 32% Zn	No. 26 High temp. cement				
63	25% Zn alloy and red brass	Mullite	500	250	$200.00	.80

red and yellow brass; and 55c and 88c per ton of metal melted respectively in the 2 other cases melting 8-18% Zn alloys with 1.5 to 7.0% Pb, pouring temperatures of which range from 1900° to 2200°F.

The installations melting red brass report from 500 to 1700 heats per lining, the charges ranging from 600 to 1000 pounds each. The tonnage per lining ranges from 250 to 510 tons.

The installation reporting 1700 heats per lining uses 600 pound charges, melting the medium red mixtures. The refractory materials used in this case are preformed, prefired blocks with special cements containing chrome ore.

Each concern reports that either no patching is possible to the body of the lining throughout its life or that very little patching is accomplished—the latter being usually around the charging door section.

ANALYSIS OF DETROIT ROCKING ELECTRIC FURNACE RESPONSES

The Detroit furnaces upon which reports were received are classified as to size as follows:

Table III.

Furnace Size	Number of furnaces represented
500 lbs. capacity or smaller	99
500 to 1000 lbs. capacity per heat	21
1000 to 2000 lbs. capacity per heat	5
2000 lbs. per heat and larger	4

The operations reported include red and yellow brass and bronze, bearing metals and nickel alloys. The products so made include valves, meter castings, automotive parts, hardware, ornamental work, fire and rubber goods castings and railway maintenance parts.

It will be seen that the reports on lining life range from 200 heats per lining to 28,000 heats, several users reporting indefinite lining life without shut-downs for relining; also that the total refractory cost varies from 25c per ton of metal melted to several dollars per ton.

This enormous variation in lining life and maintenance expense or total cost on the same general type of melting operations with furnaces of comparable capacities and operating conditions leads to the certain conclusion that much depends upon the human element in securing satisfactory refractory performance.

For purposes of analysis, the reports may be considered in groups as shown in Table IV.

In each case where a concern reported separately on more than one size furnace, each such report was treated as a separate response in the following grouping:

Table IV.

Group No.	Average number of Heats obtained per Lining	Number of concerns so reporting	Individual Refractory Costs reported per ton of metal*		
1	Less than 500	3	$4.46	$2.10	
2	500 to 1000	8	1.87	.35	$ .70
			.40	.91	.90
3	1000 to 2000	27	.82	.25	.60
			1.75	.43	.37
			.54	.69	.78
			.32	.62	.64
			1.19	.94	1.23
			.36 plus patching		
			.36 plus patching		
4	2000 to 3000	10	.42	$ .45	$2.16
5	3000 to 5000	3	.16 plus patching cost		
6	5000 to 10000	5	.11 plus patching cost		
				$ .26	$1.08
7	Over 10000	2	.285	.28	
8	Lining life indefinite	9	.28	.15	maintenance costs

*The cost figures in this column represent in each case individually reported total costs for material and labor, both new linings and patching, unless otherwise noted. The figure is included for each concern reporting on cost.

It is apparent that the lowest total refractory costs are enjoyed by those concerns who have mastered the art of patching or maintaining a furnace lining in constantly satisfactory operating condition, thus avoiding the necessity of frequent relining. Some of these concerns not only obtain thousands of heats per lining but approach, or actually attain, the condition of indefinite lining life. A number of users of this type furnace are certain that they will never have to shut down for a complete relining operation. They thereby avoid loss of production and eliminate the need of carrying spare shells to meet such a contingency. That they are correct in their attitude towards this matter seems to be borne out by the fact that their furnace linings are maintained in perfect operating condition month after month over a period of years.

The vast proportion of furnace users, however, have not attained to that degree in the art of lining maintenance. As will be seen in Table IV the largest number of users (group 3) report in the range of 1000 to 2000 heats per lining, with the second largest group (group 4) reporting 2000 to 3000 heats. A number of concerns are included in the groups between 2000 and 5000 heats who have not yet replaced their original linings. Doubtless many, if not most, of these concerns, through having established a satisfactory patching procedure, are on the way towards effecting permanent lining life from the standpoint of production shutdown for relining.

In considering Table IV, it would be misleading to consider only the number of heats per lining without regard to furnace size. The smaller units are more easily maintained and a larger number of heats per lining are necessary to secure suitably low refractory cost per ton. One thousand heats per lining with the 2000 pound or 3000 pound furnace may be a much more creditable performance than twice that number of heats with a furnace of 750 to 1000 pounds capacity per heat.

In the ultimate analysis the total cost of the finished product is the important factor. Refractory costs constitute a part of this total. They may be conveniently expressed as a certain amount per ton of metal melted, this amount including material and labor for new linings and maintenance throughout the life of the linings, being so stated wherever possible throughout this report.

In addition, however, refractory performance has a further bearing on ultimate cost through a number of secondary influences. Shut-down for relining is a matter that has already been mentioned. The expense of loss of productive capacity is obvious. Furthermore, the furnace installation producing a relatively small number of heats per lining usually has its linings in questionable condition. There is an uncertainty as to how long the lining will run, whether failure will take place and necessitate shut-down during the middle of the week, and patching expense is usually, though not always, excessive. The important point it is desired to make here is that the concern having so developed its patching technique as to keep the linings in perfect operating condition from week to week (through suitable week-end patching and morning inspection, or otherwise) accomplishes a number of important objects in securing low ultimate production costs. Direct refractory costs are lower, shut-downs are eliminated, a more efficient production schedule is maintained throughout each day and each week through the knowledge that the furnace linings are in an unquestionable condition, thereby permitting maximum speed of melting and an uninterrupted production schedule.

In Table IV, the replies are classified in accordance with the number of heats obtained per lining. It was pointed out that this classification loses much of its value unless considered in conjunction with the furnace size or refractory cost per ton of metal melted. Accordingly the furnaces are classified in Table V according to reported total refractory costs per ton of metal melted.

Table V.

Reported Refractory Cost per ton of Metal	Number of Concerns so reporting
Less than $ .30 per ton	8
$ .30 to $ .50	7
.50 to .75	5
.75 to 1.00	5
1.00 to 1.25	3
Over $1.25	5

In analyzing the reasons for the wide diversity in unit costs, we are compelled to recognize the fact that the most important single factor is the human element. The foundry personnel either has or has not the "knack" of patching a furnace lining efficiently, easily and with dependable assurance that it is in perfect operating condition. While the methods and rules for proper patching can be simply stated, and while such information is generally available to all furnace users, actual refractory results vary out of all proportion to the severity of service conditions. The plant securing only moderately good lining life and medium refractory costs may be as well managed and have just as intelligent attention paid to refractory methods as other concerns securing much more economical refractory results.

To assist in illustrating this point, it is desired to compare Responses 36 and 43. Both of these concerns manufacture light, thin-walled castings for valves and other pressure goods. The report received from each is known to be extremely accurate for each of these concerns operates an unusually efficient, well-managed foundry of the highest type. In each case the alloys melted are red brass and bronze. No. 36 reports pouring temperatures of 2175° to 2250°F., while No. 43 reports 2250°F.

Operation is 9 to 10 hours per day in each case and the charges are clean. No unusual difficulty is reported in either case with building up of slag in the furnace hearth. The only difference in the charges is that No. 36 melts 20% of clean dry chips, whereas No. 43 uses no turnings in the foundry charges. Each concern uses the same make of high-alumina fire brick in preformed, prefired shapes.

No. 36, operating 3 furnaces—

One — 75 Kw. — 250 lb. furnace
One —150 Kw. — 350 lb. furnace
One —200 Kw. — 900 lb. furnace

reports refractory costs as follows:

	250 lb. fce.	350 lb. fce.	900 lb. fce.
New lining costs	$ .38	$ .51	$ .40
Patching costs	.40	.40	.50
Total costs per ton	$ .78	$ .91	$ .90

As an illustration of the accuracy of these figures, it is noted that they comprise the average of the last 10 linings used in each type furnace as follows:

250 lb. furnace—1325 heats per lining—331,000 lbs.
350 lb. furnace— 697 heats per lining—313,000 lbs.
900 lb. furnace— 915 heats per lining—823,000 lbs.

Compare the above results with those of No. 43 as follows:

Operating 8 furnaces — 125 Kw. — 350 lb. each.
7 furnaces average –6600 heats per lining on bronze.
1 furnace averages –2000 heats per lining on Monel Metal, nickel and nickel alloys.
Patching cost (material and labor).....$ .20 per ton
New lining cost (material and labor)..... .06 per ton
Total .....$ .26 per ton

In each case the similarity of practice extends even to the use of the same patching material, a high temperature patching cement which is a calcined kaolin.

Assuming proper furnace operation in each case, i.e. correct rate of power input, correct rocking of the furnace during melting, etc., it would seem that the great difference in heats per lining and total cost might be due to the method of applying patches. No. 43 gives no detail on patching method except to state that patching starts after 400 to 500 heats have been produced on a new lining. This fact in itself predicates some condition conducive to long lining life other than correct patching of furnace linings. Is this due to clean charges with no sand on the gates and no turnings used in the furnaces? Is it due to a moderately low rate of input (120 Kw. input being carried in the 350 lb. Detroit furnaces of Respondent No. 43), thus protecting the linings against abnormal punishment; or is it due to a special method using unusual care in drying out and seasoning new linings preparatory to their being put into service? It may be that the result noted is a combination of the above conditions. We should like to point out that No. 36 states that the high temperature patching cement is trowelled into place, the cracks filled and thoroughly washed. We are inclined to think that much better results would be obtained by tamping firmly into place (even to the extent of using an air rammer where possible) rather than by trowelling. It will also be necessary and desirable to use the cement in dryer form when tamping or ramming.

Response No. 52

It is desired to call attention to Response No. 52 which is undoubtedly one of the most satisfactory and economical refractory installations in the entire list. This concern reports indefinite lining life. For the first several years of this installation 7500 to 8000 heats per lining were obtained. Latterly from 10000 to 12000 have been obtained and the present situation is that each week-end the linings are put into perfect condition for the ensuing week's run.

The furnaces are 150 Kw. — 350 lb. each. Four furnaces are used. The product being valve castings just as in the case of Nos. 36 and 43 previously discussed. The original linings in these furnaces were identical with those of Nos. 36 and 43—namely high-alumina fire brick, but in the case of No. 52, the original lining material has long since been lost sight of due to repeated patchings. The present linings in these 4 furnaces are the composite result of the materials rammed into place over week-ends during the past several years. The material used is a mixture of gannister and fire clay in the ratio 2:1. The materials are cheap, thus permitting extensive patching at very low material cost. The total cost of refractory maintenance is

Refractory materials	$ .153
Labor	.132
Total cost per ton	$ .285

Note that No. 52 carries an input of 150 to 160 Kw., thereby disposing of one of the possible explanations of the superior showing of No. 43 in comparison with No. 36. Note also that No. 52 charges 25% of dry turnings and thereby disposes of the other possible claim which might be entered against the good showing of Number 43.

In other words, No. 52, melting red brass and bronze, pouring pressure castings at 2250°F., carrying a high rate of power input for rapid melting (18 heats, 375 lbs. each per furnace per 9 hour day) and using a substantial amount of borings and scrap in the charges, using cheap refractory patching materials averages a cost of $ .285 per ton and attains the condition of having indefinitely long lining life, eliminating all question of shut-downs for relining operations.

As shown in the tabulation of responses, a number of makes and types of refractory linings are used. Several concerns use special materials such as graphite fire clay or silicon carbide fire clay preparations. By far the largest number use high alumina fire brick linings, although an increasing number are adopting Mullite or Sillimanite products.

The patching materials used include more than 20 different brands or types of refractory cements and ramming mixtures as shown in the tabulation attached, most prominent among these being Andalusite or Sillimanite and other high alumina high-temperature refractories of either Mullite or aluminous oxide type. It is of interest to note that among the half dozen concerns reporting the very lowest total refractory costs per ton of metal, each one uses a different patching material and has standardized on his own method and materials for furnace maintenance.

With regard to furnaces of larger capacity where the problem of long life and ease of maintenance is admittedly more difficult than with smaller units, it is desired to compare the refractory costs of these furnaces in view of the fewer number of heats obtained per lining.

Responses of users of the larger capacity Detroit furnaces indicate costs as shown in Table VI.

Table VI.

Response No.	Furnace Size	Alloy Melted	Number of heats obtained per lining	Total Refractory cost per ton
5	800 lb.	Bronze	700 to 1100	$ .35
7	1000 lb.	High lead	1400	.36 plus patching
8	3-2000 lb.	High lead	1000	Average $ .25 per ton
	1-1500 lb.	Brass & Bronze	1000	
	2-750 lb.		1000	
57	750 lb.	Bronze	1539 plus Still in perfect shape	
13	800 lb.	Bronze	2200 to 3000	
17	4-800 lb.	Red Brass	1000	$ .82 Total (.63 Linings .19 Patching)
22	750 lb.	High lead	350	2.10
27	3-800 lb.	Red Brass	1600	.12 patching material and labor
36	900 lb.	Red Brass	915	$ .40 linings .50 patching .90 Total
37	1-2000 lb.	Red Brass	800	
	3-1000 lb.	Red Brass	1200	

It thus appears from Table VI that while furnaces of 800 to 2000 lbs. capacity per charge do not produce the high average number of heats per lining that are obtained with the smaller units, the net costs reported for total refractory expense are on a very satisfactory basis, several of these being among the best reported.

A considerable further improvement is promised, however, by reason of the great progress made during the past 2 or 3 years in the use of monolithic linings of high temperature refractories in this type furnace for melting ferrous metals and superheating to 3000°F. and above.

Melting conditions and refractory service are infinitely more severe in iron foundry operation than in the case of any brass foundry requirement. The lining is constructed by driving the "ramming mix" into place as hard as possible with air rammers in accordance with well developed methods. Linings of this type are now in service in furnaces of 2000 to 3000 lbs. capacity, operating at high rates of power input, melting and superheating cast iron and iron alloys to above 2900°F. and have been operating from 12 to 15 months, an average of 12 hours per day, without interruption for relining or loss of any production on account of refractories. Several of these installations have attained the condition of indefinite refractory service without shut-down for relining.

This is accomplished by correct patching methods and is mentioned here with the thought that it may well be put into effect in brass foundry operation, thereby further enhancing the economy of the electric brass melting furnace.

It may be well to emphasize once more that exceptionally favorable results are usually due to the personal skill of the men who install the linings and keep them in repair. On the other hand, moderate skill, coupled with the use of simple, well known practices and precautions, is sufficient for the attainment of a very satisfactory refractory performance.

Howard McClelland, for the past 20 years connected with the open-hearth department of The Republic Steel Corporation, has joined the sales organization of Basic Dolomite, Incorporated, as service engineer. His headquarters are located at the general office of the company, 845 Hanna Building, Cleveland.

Steel and Tubes, Inc., Cleveland, Ohio, announce the following changes in personnel:

A. V. Grove has been transferred from the Cleveland office to the Chicago office in the Sales Department.

R. E. Doyle is now sales correspondent in the Cleveland office.

J. F. Keeler is now sales engineer with headquarters at the Cleveland office.

Editorial Comment

(Continued from page A 13)

with air cooling) as one legitimate method of annealing. And in the following year the term "full annealing" was originated and authenticated to identify the annealing operation when performed under furnace cooling conditions.

A lot of water has gone over the dam since the technical world was made cognizant of the joint committee's conclusions, confirmed by the coöperating societies. There has been general acceptance. Actuated by important commercial considerations, some persons who did not at first like the term "full annealing" have consistently used it and advocated its use as recommended.

Metallurgists are regarded as queer people by some folks. This impression may be the result of some Victorian tendencies. There are metallurgists who still insist on obsolete distinctions in the use of scientific terms. Recently there was published an article written by a metallurgist who dwelt at length on the fact (so declared) that normalizing is not annealing, and that great confusion results from using the term "annealing" improperly to include normalizing. The metallurgist insisted that the word "annealing" implies furnace cooling; thus completely disregarding the collective judgment of recognized experts, significantly confirmed six years ago.

The same writer, referring to steel castings, employed the term "elastic limit" for a property ascertained in the product; despite the fact that it has been established for many years that elastic limit is not determinable in cast steel by any known method. Evidently yield point was the property in mind.

Everyone who presumes to criticise takes the chance of digging a pit for himself. This may be the case now. However, the present writer subscribes fully to the policy of *trying* always to employ technical terms according to the latest accepted usage, especially in articles to be published. If metallurgists themselves do not follow this precedure there will never be an end to confusion among shop men. That's important in a very practical sense, when producing material to specifications. Incidentally, correct use of terms for heat treating the steel foundry's product has attained a new and very vital significance with the tentative adoption by the A.S.T.M. last June, of specifications (A148-33T) for alloy steel castings for structural purposes.

To avoid being misunderstood himself, the writer would explain that he was *not* a member of the joint committee that defined heat treatment terms. No personality is involved from any standpoint in this plea for the use of accredited technical terminology.—R. A. Bull

Obituary

J. H. Gibboney, Chief Chemist of the Norfolk and Western Railroad, died in Roanoke, Va., on Oct. 30, following an abdominal operation. Mr. Gibboney was 54 years old. He had been connected with the chemical department of the railroad since 1906; chief chemist since Feb. 1925.

Mr. Gibboney was president of the American Society of Testing Materials in 1926-1927 and was previously a member of its Executive Committee and a vice-president. He had been an officer of A.S.T.M. Committee A-5 on Corrosion of Iron and Steel since 1914; chairman from 1922 to his death. He was one of the six members of the important Committee E-10 on Standards and had been a member of Committee A-1 on Steel since 1913.

Prior to his services with the Norfolk and Western, he was from 1901-1903, assistant chemist in the Virginia Agricultural Experiment Station; 1903-1904, chemist of the Virginia Iron, Coal and Coke Co., and from 1904 to 1906, instructor in chemistry at Virginia Polytechnic Institute and chemist of the Virginia State Geological Survey. He was a graduate of the Virginia Polytechnic Institute.

Perkin Medal Award

Dr. Colin G. Fink, Professor of Electrochemistry at Columbia University, has been selected to receive the Perkin Medal of the Society of Chemical Industry for 1934. The medal is awarded annually for valuable work in applied chemistry and will be presented this year to Dr. Fink for his inventions in the fields of metallurgy and electrochemistry. The selection is made by a committee representative of five of the national chemical societies.

Presentation of the medal will be made at a meeting in New York early in January, details of which will be announced later.

Correction

In the August, 1933, issue of Metals & Alloys, pages 123 to 126 in the article entitled Herculoy—A Copper-Silicon-Tin-Zinc Alloy by Dr. R. A. Wilkins, the caption of the illustration at the bottom of page 126 is in error. The tetrachloride filter was not made for the American Laundry Machine Company but for G. O. Keller, Plainfield, New Jersey.

"Industrial Uses of Stainless Steel" was the title of a talk delivered before a meeting of the American Society of Mechanical Engineers at Cincinnati, Ohio, November 23, by **C. C. Snyder** of the Central Alloy Division, Republic Steel Corp., Massillon, Ohio. Prefacing his address with a brief history of the development of stainless steel, Mr. Snyder then divided the present large number of different types of stainless steel into the proper main groups, giving their general characteristics and properties.

The latter part of the talk stressed the rapidly increasing use of stainless steel in various industries, such as building, meat packing, brewing, automotive and the chemical and allied industries. Lantern slides were used to illustrate a number of typical installations of Enduro Stainless Steel.

Donald J. Reese has been appointed Manager, Foundry Equipment Division of Whiting Corporation, Harvey, Ill. Mr. Reese has been in the employ of the Whiting organization since 1920, and for several years was in active charge of the gray iron and steel foundry at the Harvey plant. Mr. Reese is a member of the American Foundrymen's Association. He has also been very active in local foundry circles and is at present Vice President of the Chicago Foundrymen's Club.

A.F.A. Annual Convention, Exposition and International Foundry Congress, Philadelphia, October 22 to 26, 1934

Executive Secretary C. E. Hoyt announces that the Board of Directors of the American Foundrymen's Association has voted unanimously to hold the 1934 Convention and Exhibition of the Association in Philadelphia, and to arrange a Convention without an exhibition for 1935.

The Executive Secretary also announces that the International Committee of foundry technical association has awarded to the American Foundrymen's Association the honor of holding in the United States in 1934, the Fifth International Foundry Congress and Exposition. The staging of this important event in connection with the annual convention of A.F.A., which is usually held in May, has been set for the week of Oct. 22, a date following the annual conventions of the coöperating European associations.

The Meetings, Exposition, and International Congress will be held in Philadelphia's new auditorium.

The overseas countries, whose foundry associations are members of the Committee on International Congresses include Great Britain, Spain, Belgium, Czechoslovakia, Italy, France, Germany and Holland. The first International Foundry Congress was held in Paris, France, in 1923, the second in Detroit, U.S.A., 1926, the third in London, England, 1929, and the fourth in Paris, France, 1932. Sixteen foreign countries were represented in the attendance at the International Congress in Detroit.

It is the plan of the directors that the 1935 Convention without an exhibit shall be similar in character to the very successful one held at the Edgewater Beach Hotel in Chicago in June, 1927, following the International Foundry Congress held in Detroit in the fall of 1926.

Preferred Orientation Produced by

COLD ROLLING
Low Carbon Sheet Steels

Some X-ray Observations

by Wayne A. Sisson*

INTRODUCTION

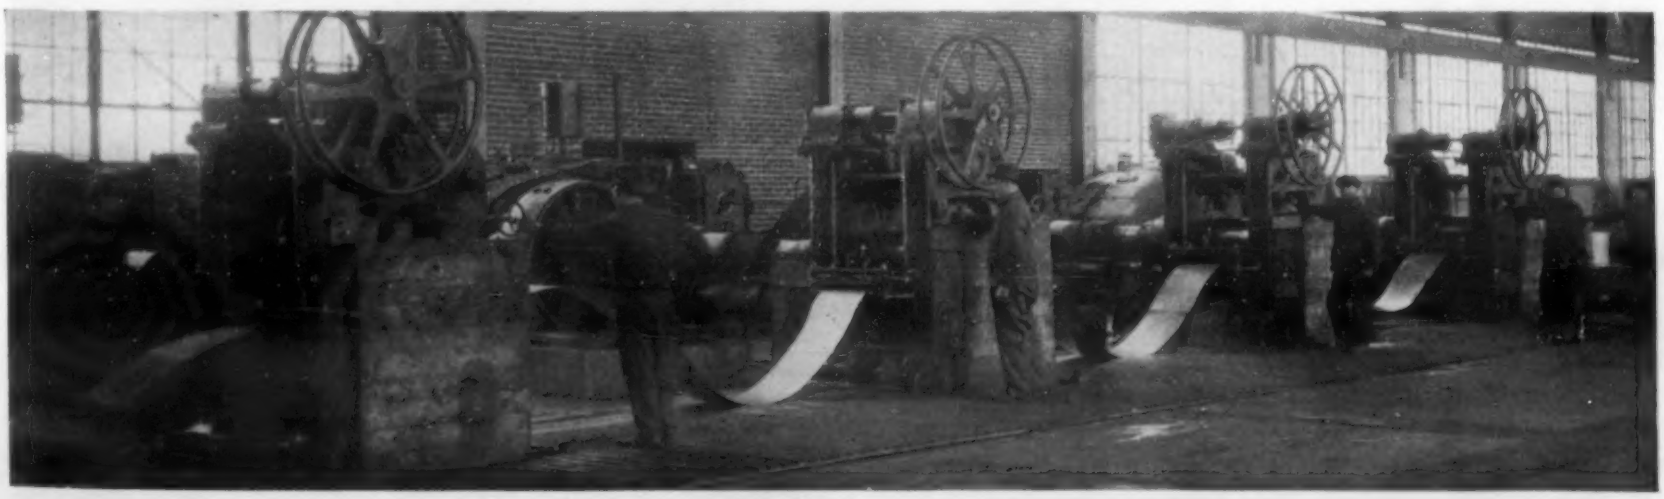
THE CRYSTALLINE orientation of rolled metals and hard drawn wires were first explained by Uspenski and Konobejewski,[1] Becker and Polanyi,[2] Ettisch,[3] and Mark and Weissenberg[4] and later by Jeffries.[5] These and other investigators have shown that the X-ray patterns obtained from cold deformed metals were due to the rearrangement of the crystallites from a position of random arrangement in the annealed metal to positions of definite orientation, and have given an explanation for the production of such orientations. With the hope of obtaining information regarding the inner processes of plastic deformation, many investigators have since studied the texture produced by various processes of cold deformation. Discussions of these results have been published repeatedly and will not be reviewed.

As pointed out by Wever,[6] the original investigations gave rise to hopes which have been fulfilled only in part due to the contradictory results obtained on various cold-rolled foils. This lack of agreement is accounted for, in part, by Wever as follows: "The macroscopic features of the rolling process show that this deformation is definitely heterogeneous in character and that it is subject to influences from the most varied sources. From this it is clear that the texture will vary from point to point and that it may be affected by such factors as the roll diameter, the reduction per pass, the number of passes, etc. Again various observations[7] suggest that the fine mechanism of the process varies (or may vary) fundamentally in the course of the reduction."

It was thought to be of interest, therefore, both from a practical and theoretical standpoint, to investigate the course of changes in crystal fragmentation and orientation during successive stages in the rolling process; also to study the effect of variables in the raw material and in the technique of rolling upon the establishment of the ultimately attained preferred orientation. It is the purpose of this paper to outline briefly a long series of studies of these problems.

*Résumé of part of thesis submitted by W. A. Sisson to the Graduate School of the University of Illinois in partial fulfillment of the requirements for the degree of Doctor of Philosophy, under the direction of Prof. George L. Clark.

EXPERIMENTAL TECHNIQUE



Open hearth low carbon steel, analyzing approximately 0.1% C, 0.4% Mn, 0.04% S and 0.014% P was used in this investigation because of its commercial importance. The majority of samples were rolled on the Steckel type of rolling mill,[8] several on standard types of rolling mills, and a few on small hand-driven rolls.

The methods outlined by Davey, Nitchie, and Fuller[9] and by Polanyi[10] were used to determine the type of fiber structure for the samples examined. The degree of orientation was determined by the sharpness of the intensity maxima, or by direct comparison of the diffraction patterns. The large number of specimens examined prohibited the more quantitative face-pole figures of Wever[33] to be constructed for each sample. An example of the interpretation of the type of pattern obtained from cold rolled steel is given by Clark.[11]

Gough[12] has shown the slip mechanism to be more complicated than originally thought but throughout this paper it will be assumed that slip takes place on the (110) planes.[13]

Apparatus

The X-ray machine was of the type manufactured by the General Electric Company[14] containing a Coolidge tube with a molybdenum (Ka = .71 A.U.) water-cooled target operating at 30 kilovolts and 20 milliamps. In most cases the Laué method employing polychromatic radiation was found to be the most satisfactory for studying preferred orientation. The same pinhole was used in examining each specimen of a series containing a common variable. The specimens were mounted over the outer aperture of the pinhole system with the direction of rolling vertical and perpendicular to the X-ray beam. The photographic film in a flat aluminum cassette was placed 5 cm. from the specimen. In some cases a reflection method similar to that employed by Davey, Nitchie and Fuller[9] was used. In order to carry out quantitative studies on orientation the specimen was tilted at definite angles to the X-ray beam, by employing a special constructed goniometer which allowed the specimen to be rotated ± 50°.

Two-High Tandem Cold Rolling Mills (Courtesy E. W. Bliss Company).

Selection of Uniform Samples

Schmid and Wasserman[15] have shown that drawn wires have a distinctly zonal structure. Similar zonal differences in rolled metals have been reported by Tafel,[16] Niwa and Matura[17] and Thomasson.[18]

In selecting comparable samples for examination some idea of the uniformity of the cold rolled sheet structure is desirable. Transmission patterns of specimens prepared from various zones in a sheet showed that thick samples, having a small percent reduction, had a slightly greater grain fragmentation and preferred orientation near the surface. Thin samples, having a large reduction, appeared to be essentially uniform throughout. It is probable that a greater difference in surface and interior would have been found for driven rolls where the surface resistance is greater than that present for the type of rolls used in this experiment.

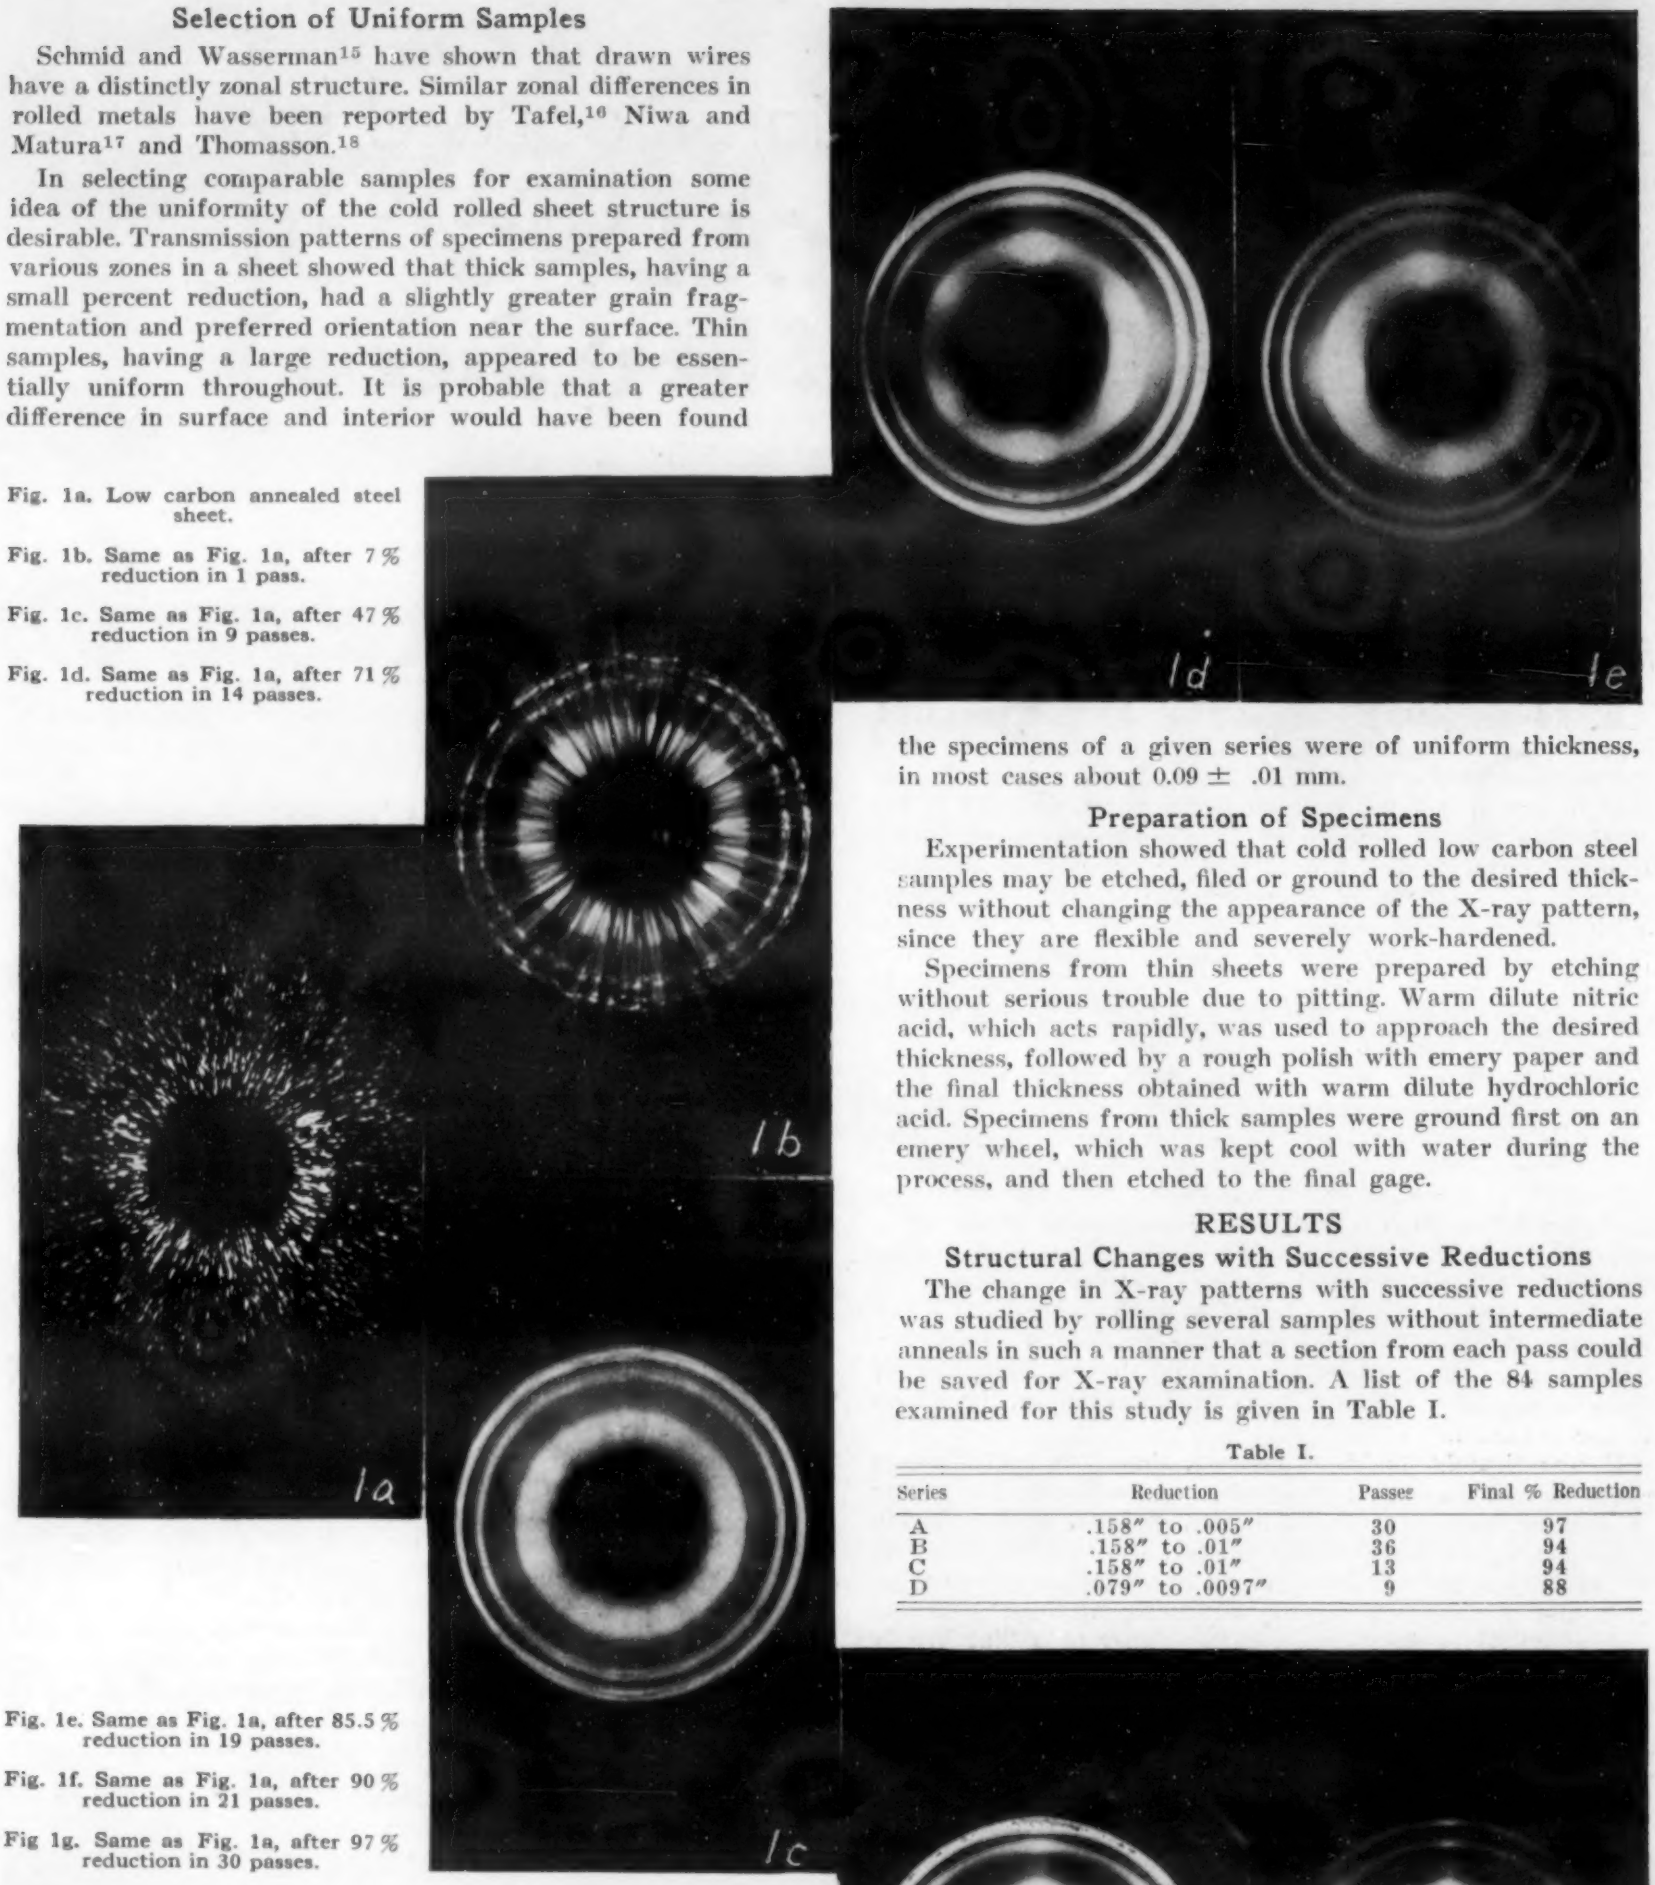


Fig. 1a. Low carbon annealed steel sheet.

Fig. 1b. Same as Fig. 1a, after 7 % reduction in 1 pass.

Fig. 1c. Same as Fig. 1a, after 47 % reduction in 9 passes.

Fig. 1d. Same as Fig. 1a, after 71 % reduction in 14 passes.

Fig. 1e. Same as Fig. 1a, after 85.5 % reduction in 19 passes.

Fig. 1f. Same as Fig. 1a, after 90 % reduction in 21 passes.

Fig 1g. Same as Fig. 1a, after 97 % reduction in 30 passes.

In order to avoid the "fish tail" effect[19] and to minimize the possibility of a banded structure,[20] which usually occurs near the center of the strip, the specimens examined in this investigation were taken about an inch from the edge of the sheet.

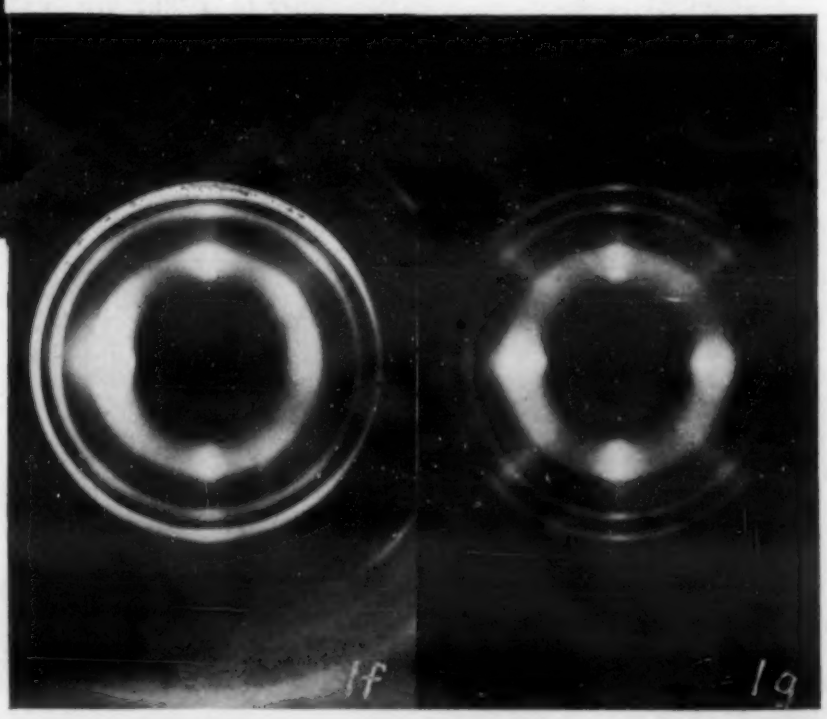
Specimen Thickness

The effect of sample thickness was studied quantitatively in order to obtain information concerning the most desirable thickness to use when taking transmission diffraction patterns of low carbon steel. A set of patterns taken every 0.02 mm. from 0.25 to 0.02 mm. thickness, showed 0.08 to 0.1 mm. to be the most satisfactory. Throughout this investigation the specimens of a given series were of uniform thickness, in most cases about 0.09 ± .01 mm.

Preparation of Specimens

Experimentation showed that cold rolled low carbon steel samples may be etched, filed or ground to the desired thickness without changing the appearance of the X-ray pattern, since they are flexible and severely work-hardened.

Specimens from thin sheets were prepared by etching without serious trouble due to pitting. Warm dilute nitric acid, which acts rapidly, was used to approach the desired thickness, followed by a rough polish with emery paper and the final thickness obtained with warm dilute hydrochloric acid. Specimens from thick samples were ground first on an emery wheel, which was kept cool with water during the process, and then etched to the final gage.



RESULTS

Structural Changes with Successive Reductions

The change in X-ray patterns with successive reductions was studied by rolling several samples without intermediate anneals in such a manner that a section from each pass could be saved for X-ray examination. A list of the 84 samples examined for this study is given in Table I.

Table I.

Series	Reduction	Passes	Final % Reduction
A	.158″ to .005″	30	97
B	.158″ to .01″	36	94
C	.158″ to .01″	13	94
D	.079″ to .0097″	9	88

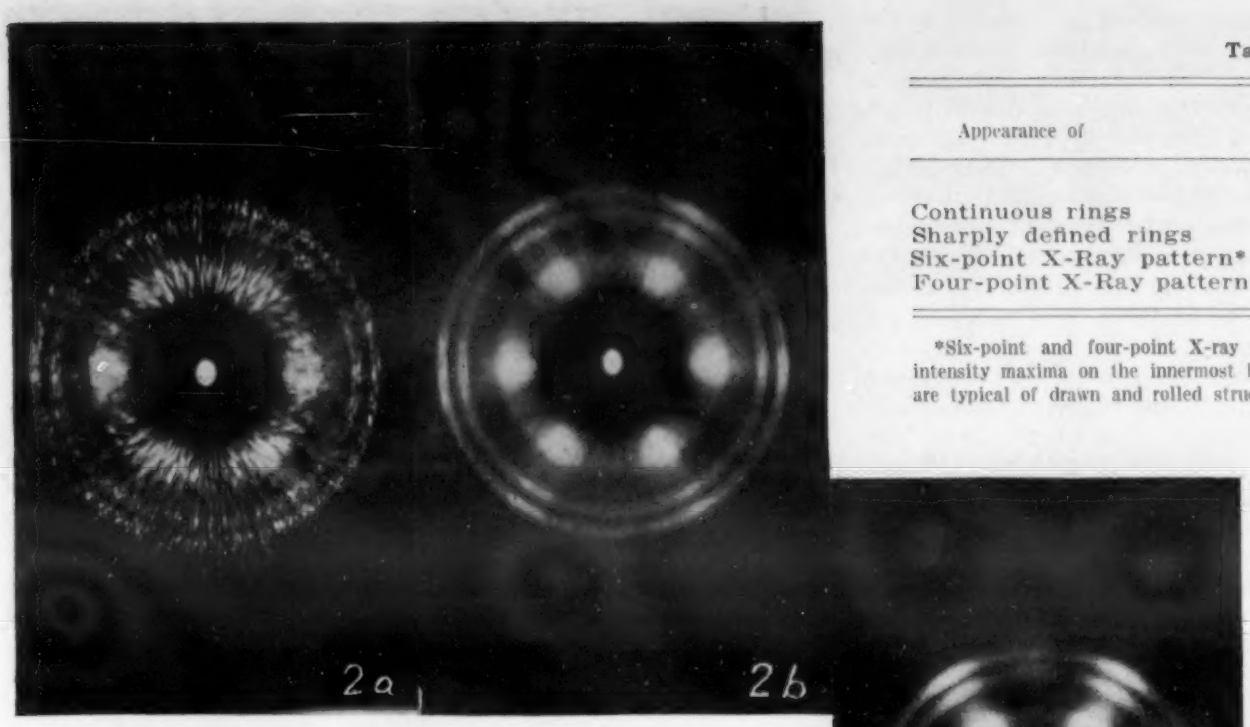


Table III.

Appearance of	Series Per Cent Reduction				
	A	B	C	D	Average
Continuous rings	25	26	35	20	27
Sharply defined rings	31	40	43	27	38
Six-point X-Ray pattern*	70	50	52	45	54
Four-point X-Ray pattern*	83	74	79	70	76

*Six-point and four-point X-ray patterns refer to the number of localized intensity maxima on the innermost band. The six-point and four-point patterns are typical of drawn and rolled structures respectively.

Fig. 2a. Low carbon hot rolled steel sheet with X-ray beam perpendicular to rolling direction and parallel to rolling plane.

Fig. 2b. Same as Fig. 2a, after 16 % reduction.

Fig. 2c. Same as Fig. 2a, after 36.5 % reduction.

The results are represented by Figs. 1a to 1g which were taken from series A. Data concerning these figures are given in Table II.

Table II.

Figure	Pass	Gage inches	Percentage Reduction	Remarks
1a	0	0.158 hot rolled strip	0	Large random grains.
1b	1	0.1475	7	Grain fragmentation and distortion, appearance of diffraction rings.
1c	9	0.084	47	Advanced fragmentation random orientation uniform rings.
1d	14	0.046	71	Appearance of 6 point fiber pattern characteristic of drawing.
1e	19	0.023	85.5	Passing from 6 to 4 point pattern.
1f	21	0.0165	90	Typical rolling pattern, "limited" fiber structure.
1g	31	0.005	97	More perfect orientation.

Here the X-ray beam passed perpendicular to the rolling direction and to the surface of the sheet. Somewhat similar results are shown by a series of reflection patterns reproduced in Iron Age[21] for the successive reduction of a strip of low carbon steel reduced 84.3% in 12 passes.

From the whole series of steel samples the following average results were obtained.

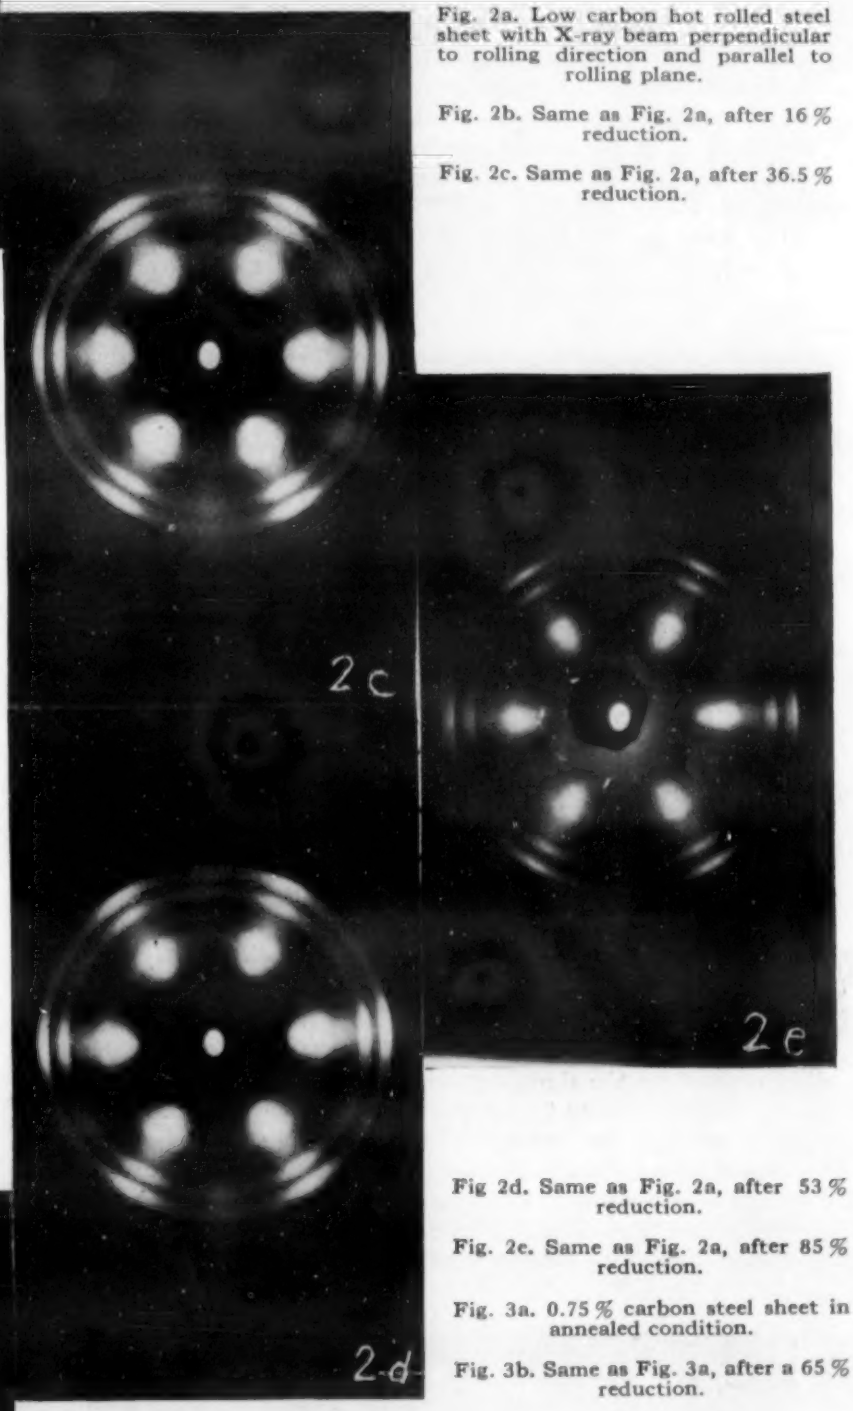

Fig 2d. Same as Fig. 2a, after 53 % reduction.

Fig. 2e. Same as Fig. 2a, after 85 % reduction.

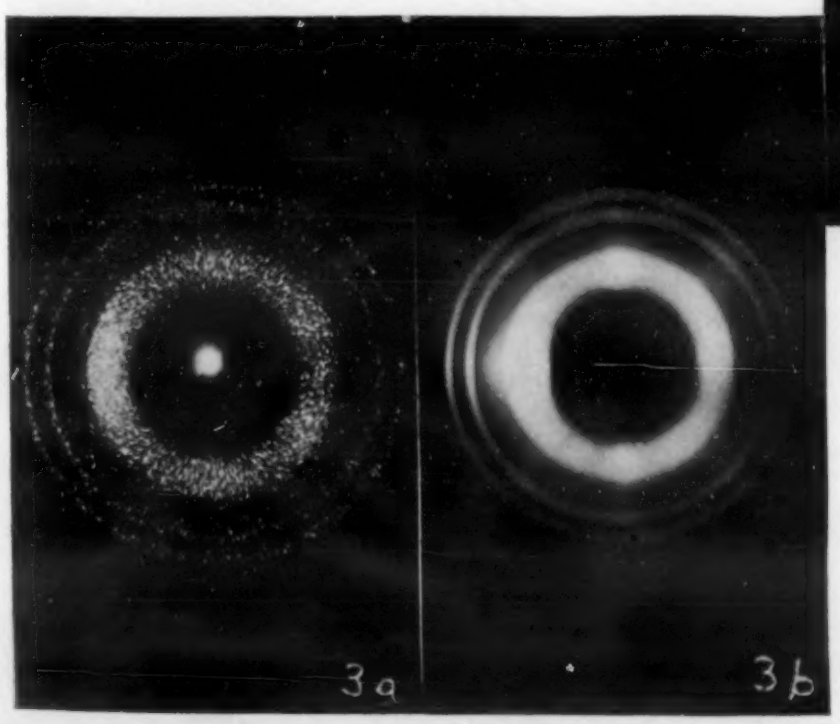

Fig. 3a. 0.75 % carbon steel sheet in annealed condition.

Fig. 3b. Same as Fig. 3a, after a 65 % reduction.

As will be shown later, these values are only representative and will vary, depending upon the chemical composition, thickness, grain size and orientation of the original starting material.

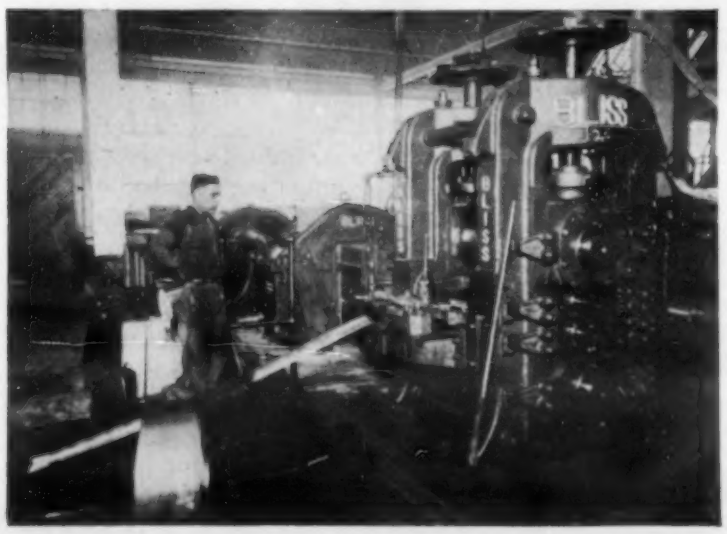
These results confirm those of Tammann[22, 23] who found that in rolling 2 clearly defined changes in crystal orientation can be distinguished: the first in which the force due to rotation of the rolls acts as a stretching force (6-point X-ray pattern), and the second in which the action of the rolls is similar to that of simple compressions (4-point X-ray pattern) and this exerts by far the greater influence on the final orientation in cases of large reductions.

Crystal rotation.—If the X-ray beam is made to pass through the specimen perpendicular to the rolling direction and

parallel to the rolling plane, the rotation of the crystals in the plane of the sheet may be studied. An appreciable rotation may usually be noticed after a 10 to 30% reduction. This gives a six-point X-ray pattern similar to that for cold drawn wires. Norton and Hiller[24] have shown that this type of pattern is to be predicted from calculations. With larger reductions the intensity maxima become sharper and it was found that if the sines of the angles of the arcs formed by these intensity maxima are plotted against the percent reduction the values approach a straight line. Data from a large number of specimens indicate that this relationship holds within an accuracy of about 10%.

Typical X-ray patterns with the beam perpendicular to the rolling direction and parallel to the rolling plane, for reductions of 16, 36.5, 53 and 85%, are shown in Figs. 2a, 2b, 2c and 2d respectively.

Effect of Orientation on Physical Properties.—An attempt was made to correlate the change in physical properties with the change in orientation. In general the tensile strength and hardness increased proportional to the rotation of the crystals and appeared to reach a maximum value as a state of perfect preferred orientation was approached. Curves similar to those given by Pomp and Weichert[25] were obtained.



The resistance to further reductions, as measured by power consumption of the rolling mill, was found to increase in the same manner as the physical properties.

These results seem to indicate that the increased tensile strength, hardness and resistance to deformation is partly due to the orientation of the crystals which have changed to positions less favorable for slip and partly due to the small size of the grain fragments which give slip interference.

Effect of Variables in Original Material on Orientation Grain Size.—The effect of grain size in the starting material upon the structure of cold drawn low carbon steel wires has been reported by Clark.[11] Data from several samples showed that the grain size of the starting material has considerable influence upon the structure of cold rolled steel during early stages of reduction, but after large reductions the effect is lost. The smaller the initial grain size, the less cold work is required to produce fibering.

Initial Strip Thickness.—Data from several samples showed that the degree of fibering depends not only on the percentage reduction but also on the initial strip thickness. A sample reduced from 0.08 to 0.01 in. does not show the same degree of preferred orientation as one reduced from 0.04 to 0.005 in., although both have received 87.5% reduction.

Carbon Content.—Most of the previous work on orientation in cold-rolled sheets has been carried out in pure metals. In high carbon steels the pearlite is hard and more brittle than ferrite with the result that when pearlitic steel is cold rolled gliding takes place in a complex manner. The cementite is probably dispersed while the ductile ferrite forms a plastic bond which is not oriented, so as to form a straight fiber structure, but is curved around the cementite particles. The X-ray pattern, therefore, gives the appearance of a more random arrangement for high-carbon steels. Other impurities in iron may have an effect similar to carbon.[11] Plates 3a and 3b show a 0.75% carbon sheet before and after a 65% reduction.

Four-High Cold Mill (Courtesy E. W. Bliss Company).

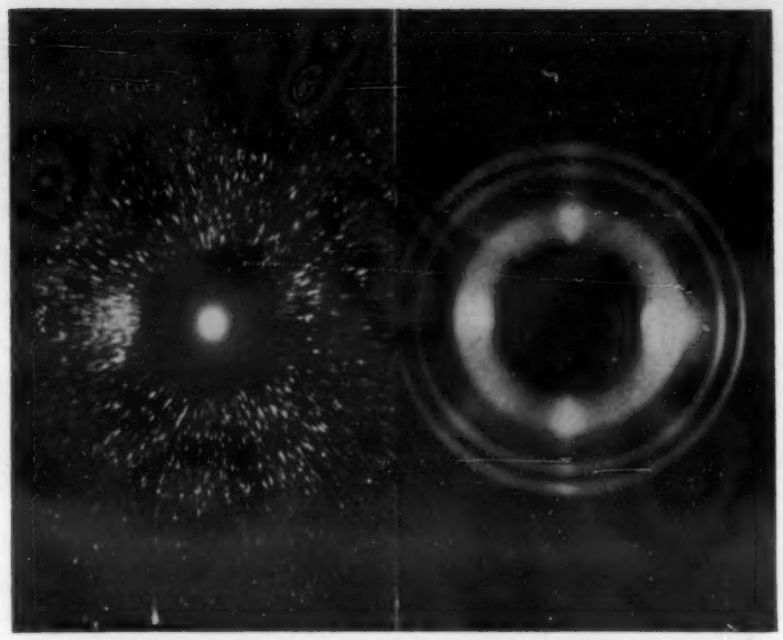


Fig. 4a. Low carbon steel sheet in annealed condition.

Fig. 4b. Same as Fig. 4a, after an 80 % reduction in one pass.

Effect of Rolling Variables on Orientation

Wever and Schmid[26,6,27,28] have reported that the final predominating fibre structure of face-centered metals depends to a large extent upon the type of mill and method of rolling. Hollabaugh and Davey[30] confirmed these results for Al, but not for Cu and Ni. It is of interest to see what effect rolling variables may have upon the orientation of low C steels.

In the following experiments the samples for comparison were obtained from the same original coil so as to eliminate, as far as possible, the effect of composition.

Roll Diameter.—The difference in power requirements, forces set up, etc., for large and small diameter rolls has been discussed by Caswell[19,29] and others. If the diameter of the rolls become infinitely large then the deforming forces under the rolls approach that of pure compression applied normal to the sheet. If they become very small, so that the sheet must be pulled through the rolls, then the deforming forces approach those in a drawing die. Since the type of orientation obtained by drawing is reported to be different from that obtained by rolling, the effect of roll diameter upon the structure was studied.

Comparative tests made with different diameter rolls are listed in Table IV.

Table IV

Diameter of Rolls	Original Thickness	Final Thickness	% Reduction
12″	.089″	.01″	89
2¼″	.089″	.01″	89
5″	.08″	.01″	87.5
2¼″	.08″	.01″	87.5
2¼″	.065″	.01″	84.5
1½″	.065″	.01″	84.5
24″	.08″	.024″	70
12″	.08″	.024″	70

In each case the original material was reduced to the final gage without intermediate anneals. X-ray spectrograms taken of each sample rolled for comparison showed that in every case the degree of preferred orientation was practically independent of the roll diameter.

Speed of Deformation and Reversal of Strip.—Investigation showed that with small rolls the same structure is obtained at rolling speeds from 70 to 800 ft. per minute. The orientation is also the same for unidirectional or for reversed passes through the rolls.

Percent Reduction Per Pass.—X-ray patterns of sheets reduced 87% with 10 to 20% reductions per pass, showed that the final orientation was independent of the percent per pass in obtaining the reduction. This was further proved by reducing a sheet from 0.065 in. to 0.013 in. in one pass, which is an 80% reduction. Plate 4a and 4b show X-ray patterns of this sample before and after the large reduction. A second piece of the same raw material was reduced the same amount in 12 passes and the X-ray pattern of the reduced sample showed the same degree of fibering as that reduced in one pass.

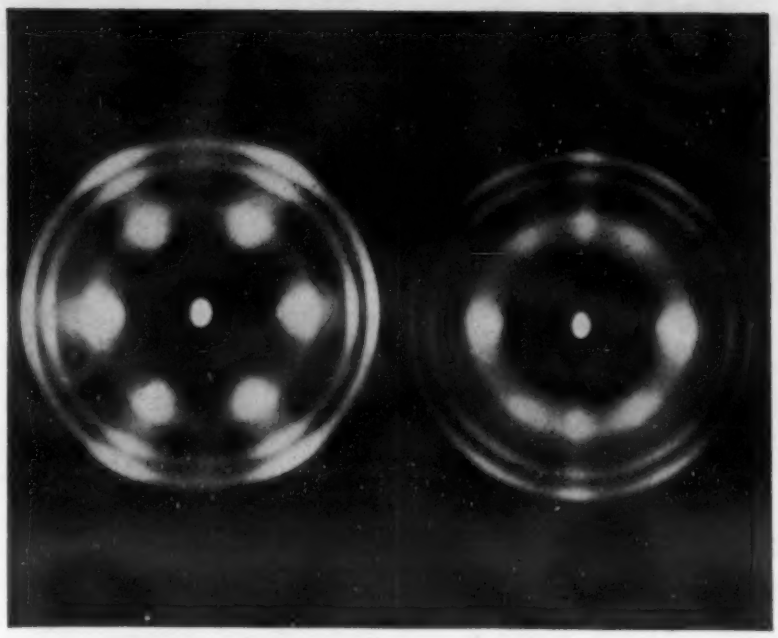

Fig. 5a. Cold drawn low carbon steel wire.

Fig. 5b. Same wire Fig. 5a, after 90 % reduction by rolling.

Effect of Deformation Due to Both Tension and Compression on Orientation

In an effort to obtain more information regarding the part which tension and compression play in producing the final orientation in cold rolled steel the following combinations of tension and compression were studied.

Applied Tension during Rolling.—This application of tension was accomplished by employing a mill of the type described in Iron Age,[8] equipped with a special brake which allowed any desired amount of back tension to be applied as the strip passed through the rolls. Strips 2 inches wide were rolled from 0.0775 in. to 0.0095 in. in 12 passes. The pounds tension per square inch in the strip for the 4 experiments tried were: none, 19,750, 30,800 and 49,200. X-ray photographs of each final pass and of each step in the reduction throughout the range where preferred orientation was being established, showed that the application of tension below the elastic limit did not affect the establishment or final degree of preferred orientation.

Effect of Stretching Followed by Rolling.—For this study narrow uniform strips were given various amounts of elongation up to 40%. These strips were then rolled on hand-driven rolls. X-ray patterns showed that the appearance of a limited fiber structure (typical of rolled sheets) could be delayed by elongating the sample by tension before rolling. However, this preliminary elongation did not affect the final orientation after a total 80 or 90% reduction.

Reduction by Hammering and Stretching.—Sheets of low carbon steel were deformed by various combinations of compression and tension. X-ray examination of a large number of samples showed that if a sheet is reduced by compression or tension the metal must flow in one direction if a condition of preferred orientation characteristic of rolled sheets is to be established. If the metal is allowed to flow in all directions the cube diagonals become parallel to the plane of the sheet but have no preferred direction in this plane.

Drawing of Flat Sheets.—In cold drawn wires the crystallites are oriented with respect to the wire axis but are rotated at random around this axis. The question then arises as to whether this type of orientation is due to tension alone or is affected by the process of reduction through a die. If the fiber condition is due to tension alone then a flat drawn sheet should have a fiber structure typical of drawn wire instead of a rolled sheet. In order to test this theory, narrow sheets of low carbon steel were reduced by drawing in a specially constructed die. 50% reduction was the maximum to be obtained by drawing. Investigation showed that the drawn sheets had the same type of fibering as sheets rolled the same amount. These results indicate that *the direction of flow of the metal is the factor which determines the nature of the fiber structure*, rather than whether the material is drawn or rolled. These results agree with those obtained by Norton and Hiller.[24]

Rolling of Drawn Wires.—In order to throw more light upon the mechanism of the establishment of orientation, cold drawn low carbon steel wires having a well defined fibre structure were rolled and the change in orientation studied during the rolling process. This investigation showed that the orientation of the [110] direction did not change during the rolling process, but there was a rotation of the crystallites around this direction until a (100) plane became parallel to the rolling plane (limited type of fiber structure). Plate 5a and 5b show a cold drawn low carbon steel wire before and after a 90% reduction by rolling.

As pointed out by Wever,[6] the relation between the type of preferred orientation produced by tension and by compression does not become evident until we take into account that it is the symmetry of the direction of flow, rather than the axis of symmetry of the applied stress, that is of significance. In drawing wire or in tensile tests, this symmetry of direction of flow coincides with the wire axis (or tensile axis), while in compression or rolling it lies in a plane perpendicular to the direction of compression.

Rolling at Various Angles.—Upon examination of a body-centered cubic lattice we see that it has a 4 fold symmetry around an axis normal to the cube face. Therefore, if the unit cube tends to arrange itself during the rolling process so that the face diagonal is parallel to the rolling direction and the cube face parallel to the rolling plane, the same orientation should be obtained by rolling in 2 directions at right angles to each other as that obtained by rolling all in one direction. Furthermore, cross rolling should cause a condition of preferred orientation to be established with less reduction since the passes at right angles should help to rotate the crystallites into a final position.

In order to test the correctness of the above predictions the following sheets having random arrangement were rolled on small hand driven rolls.

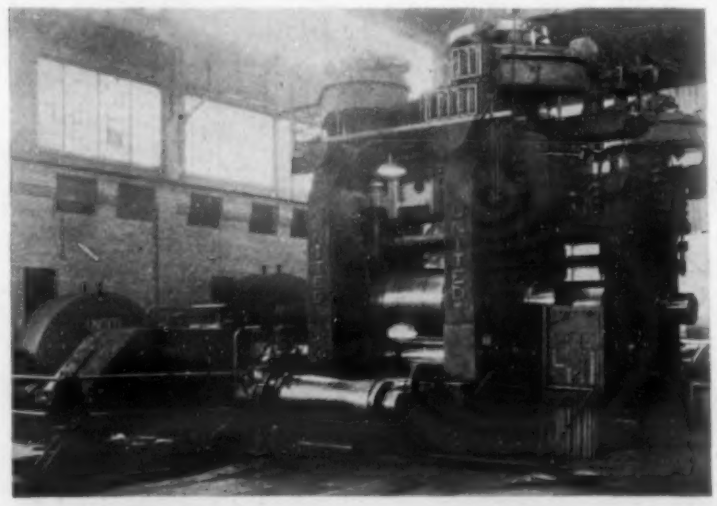

Table V

Original Thickness	Final Thickness	Percent Reduction	Rolling Angle	Directional Properties*	Preferred Orientation
.01″	.004″	60	180°	Present	Present
.01″	.004″	60	90°	Absent	Present
.01″	.004″	60	30°	Slight	Absent
.065″	.0028″	96	180°	Present	Present
.065″	.0028″	96	90°	Absent	Present
.065″	.0028″	96	30°	Slight	Slight

*As shown by bending tests.

The X-ray patterns for the 96% reduction by cross and 30° rolling are shown in Figs. 6a and 6b. The orientation is sharper than that obtained by unidirectional rolling. Examination of intermediate steps showed that the final orientation is established with less reduction for cross rolling.

Von Göler and Sachs[31] studied the rolling and recrystallization structure of copper rolled in various directions. They found that cross rolling gave an entirely new symmetry to the X-ray pattern. This difference between copper and iron is to be expected because of the difference in crystal structure and type of preferred orientation obtained for rolled sheets.

Four-High Cold Strip Mill (Courtesy United Engineering and Foundry Company).

In view of the above facts it is probable that we can further limit our general rule stated above (that the type of preferred orientation depends upon the symmetry of the direction of flow, rather than upon the symmetry of the applied stress) to take into account the symmetry of glide planes in the metal being deformed.

It is well known that the physical properties of cold rolled low carbon steel sheets are different depending upon whether they are determined in the direction parallel or perpendicular to the rolling plane.[32] This difference is usually attributed to the condition of preferred orientation existing within the sheet. However, preliminary results indicate that cross-rolled sheets are almost free from directional physical properties and yet produce an X-ray pattern indicative of almost perfect preferred orientation. The question then arises why should any cold rolled steel sheet having a preferred orientation show directional physical properties. It is probable that the answer to this question may be found in the fact that more glide planes have been used in one direction than in the other. By the way of practical application of the above phenomenon, it is probable that many of the difficulties of certain drawing operations could be remedied if the steel could be made to flow in two directions during the forming operation so as to partly eliminate directional physical properties.

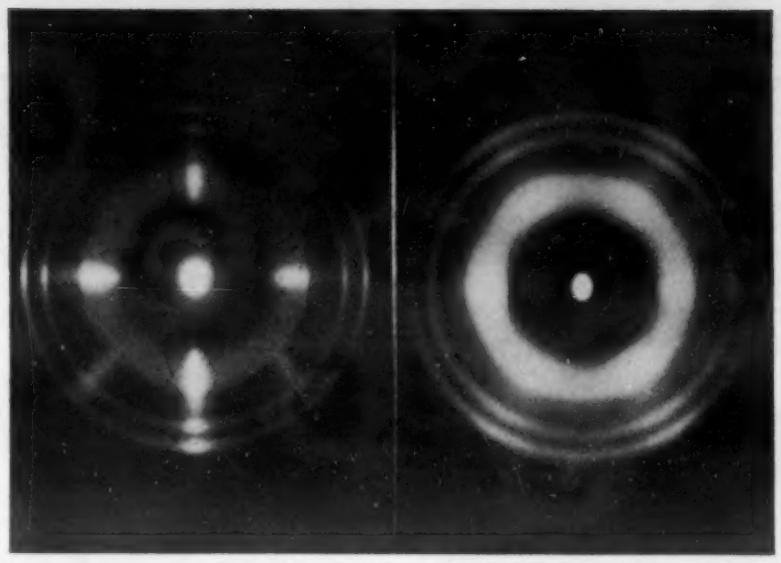

Fig. 6a. Low carbon sheet after 96 % reduction with each pass perpendicular to last.

Fig. 6b. Same material and percent reduction as Fig. 6a, but with each pass 30° to last.

SUMMARY

The authors realize that due to the variable nature of low carbon steel, many of the conclusions drawn in this paper may require modification if applied to other materials or experimental conditions. Space has not permitted the presentation of experimental data in detail, but the conclusions in general contribute information concerning the mechanism of plastic flow and the resulting fiber structure as affected by variations in the raw material and method of deformation. The results may be summarized as follows:

A discussion is given of the technique of selecting and preparing specimens for X-ray examination.

The change in orientation of the crystallites of low carbon sheet steel during successive stages of reduction was investigated by X-ray diffraction methods with the beam both parallel and perpendicular to the rolled sheet, and the results of other investigators confirmed.

The relation between orientation and physical properties is pointed out.

The degree of preferred orientation in a cold rolled low carbon steel was found to depend not only upon the percent reduction which the sample had received, but also upon the grain size, thickness and chemical analysis of the original starting material.

Low carbon steel is not very sensitive to differences in rolling treatment, as indicated by the fact that the degree of preferred orientation was found to be independent of the roll diameter, speed of deformation, reversal of strip and the percent reduction per pass.

The application of tension below the elastic limit to the strip during the rolling process does not effect the establishment or final degree of preferred orientation.

The appearance of preferred orientation may be delayed by elongating the strip prior to rolling, but the final type of orientation is not affected.

The type of orientation produced by hammering and stretching is discussed.

Sheets drawn through a flat die give the same type of preferred orientation as rolled sheets.

The rolling of cold drawn wires changes the fiber structure from an "unlimited" to a "limited" type.

The results obtained by rolling low carbon steel sheets at various angles and its effect upon directional properties of the sheet are discussed.

The results as a whole confirm the theory that the type of preferred orientation produced in low carbon steel depends upon the symmetry of the glide planes and the symmetry of the direction of flow of the metal, rather than upon the axis of symmetry of the applied stress, or whether the deformation is produced by tension or compression.

Important industrial uses for metals are definable, in the minds of producers, in terms of tonnage, in those of users, in terms of added satisfaction. The small boy will appreciate having louder torpedoes for the 4th of July. Personally, we won't get any great satisfaction from that particular use, but improvement in ammunition hits nearer home. We can utilize that 10 or 15% reduction in "barrel time" on the skeet targets from station 8.

Anything with new and different properties seems destined sooner or later to have those properties utilized, providing the cost is low enough. In metals, eliminating the impurities that obscure the special properties, tedious determination of those properties and then getting the production cost down have to be accomplished before the uses develop.

Those who deal with rare metals and have the patience and the finances to carry them to such a stage may reap a profit. Anyhow, the research men who finally lick the difficulties have had a lot of fun in doing so.

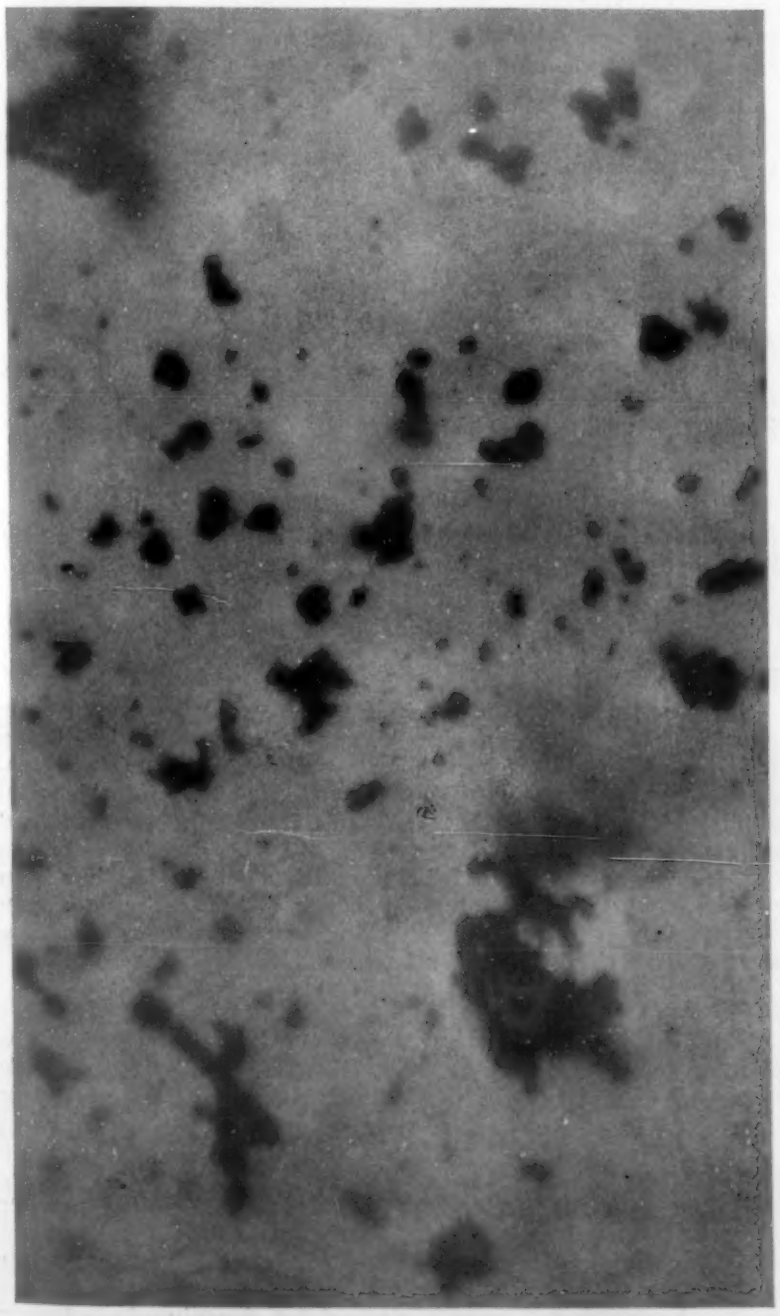

Fig. 1. Zirconium, Grade CM; magnification 2500×; particle size from <0.4 μ to 8 μ.

ZIRCONIUM

by Gordon H. Chambers*

WITHIN the past three years another element has joined the rank of commercial metals. As late as 1929 zirconium sold for $25.00 per lb. and the pure metal had no commercial use. The next year a sudden demand was created when several manufacturers of photographic supplies brought out a new "smokeless" flashlight powder. The new flashlight mixture contained roughly 13½% magnesium, 58% barium nitrate and 28½% of finely divided zirconium metal. The zirconium produced a brilliant flash with high actinic power but, more important, in burning it formed a heavy ash and the flashlight powder was therefore smokeless. Instead of depositing white magnesia dust on the curtains, the ardent photographer now put zirconia ash on the rugs. This flashlight powder became popular and a real market for zirconium metal was created. In response to this an American manufacturer began to produce it. The price dropped to about $8.00 per lb. in late 1930.

However, the infant zirconium industry soon received a severe blow. Photoflash bulbs were introduced and the flashlight powder business almost vanished, taking with it the principal market for zirconium. The photoflash bulbs created a new use for zirconium but a very small one. It is used in the ignition composition which is coated on a fine bridge wire. The mixture flashes when an electric current heats the wire and the flaming zirconium ignites the aluminum foil in the lamp.

Fortunately, the untimely death of the flashlight powder business was only a temporary setback. Other uses for zirconium were developed as the manufacturers gradually realized the unusual properties which the metal possessed.

Physical Properties

Zirconium Metal Powder is extremely fine, screen tests showing only 1% held on 325 mesh. The photomicrograph (Fig. 1) gives a general idea of the structure. The high magnification of the picture shows that the metal particles are extraordinarily small. One investigator estimated that the grains of commercial zirconium metal were only 0.4 μ to 8. μ in size (1μ = 0.001 mm.). An ultra-microscopic examination by the Bureau of Mines showed that the metal was of colloidal fineness and had a marked tendency to form flocculent aggregates. The Bureau reports that many of these aggegates were of sufficient fineness to display Brownian movements in aqueous suspension.

Zirconium metal is stable at ordinary temperatures but will ignite in air at temperatures ranging from 210° to 275° C. The manufacturers and larger consumers of zirconium have found ignition point tests to be the most effective method of checking the uniformity of the metal. The ignition point is proportional to the fineness of the metal particles, the larger grains having higher ignition points. For certain uses an ignition point of 210° C. is preferred and therefore each batch of this grade is allowed a tolerance of about 5°. It must ignite between 205° C. and 215° C. Other grades are controlled in the same way.

Zirconium is black or dark gray in color. It is quite hard, the hardness on Mohs scale being 6.5. The melting point of commercial zirconium is at least 2130° C. and is probably higher. The atomic weight is estimated to be 91.2 or 91.3 which is close to that of molybdenum, 96. Our laboratory recently checked the specific gravity of the powdered metal and reported it to be about 5.855.

Chemical Properties

The chemical stability of finely divided zirconium metal is remarkable. This is, perhaps, its most unusual and valuable property. The metal does not deteriorate in air and in this respect is superior to powdered aluminum, magnesium, the rare earths and almost all other powdered metals. In one test zirco-

*Secretary, Foote Mineral Company, Inc., Philadelphia.

nium was kept in a saturated atmosphere at a temperature of 125° F. for a period of 9 months and at the end of that time it did not show the slightest perceptible oxidation and its physical characteristics were unchanged. At least 10 industrial laboratories have made tests on the stability of zirconium and all of them have found it stable under heat, humidity and when mixed with alkaline salts or acids. It resists the action of hydrochloric and nitric acids in all concentrations and is also resistant to dilute sulphuric acid. Hydrofluoric acid is the only really good solvent for pure zirconium metal.

In sharp contrast to its stability at room temperatures, zirconium is a very reactive metal when heated. It combines with all gases, except the rare gases. It is rapidly oxidized when ignited and burns in less than 0.001 second, liberating a tremendous amount of heat. The heat of combustion is about 1956.7 calories per gram. It has a great affinity for oxygen and is peculiarly efficient in rapidly extracting this gas from somewhat sluggish oxidizers such as barium nitrate.

Other oxidizers which have been used with zirconium are potassium chlorate, lead peroxide, red lead, lead nitrate and the double salt of barium nitrate and potassium nitrate. The relative efficiency of several of these oxidizers with zirconium is shown in the following table of comparative impact tests. The mixtures are loaded into caliber .30 primer cups and tested on a drop test apparatus. In the first test the drop ball weighed 10 ounces and fell from a height of 18 inches. The mixtures were tested in lots of 25, the figures indicating the number in each lot igniting on the first drop, then the number igniting on the second drop, etc.

Series I. 10 oz. Ball Dropped 18 Inches.

	32% Zr Metal 48% $Ba(NO_3)_2$ 20% Granulated Glass	32% Zr Metal 48% PbO_2 20% Granulated Glass
Ignited on 1st drop	13	23
" " 2nd "	1	0
" " 3rd "	0	2
" " 4th "	4	0
Missfire	7	0

This test shows that lead peroxide is a more efficient oxidizer for zirconium than is barium nitrate.

Series II. 8 oz. Ball Dropped 15 Inches.

Oxidizer	Zirconium	No. Tested	No. Fired	No. Squibs
66.6% $KClO_3$	33.3% Zr	100	73	0
66.6% $Ba(NO_3)_2$	33.3% Zr	100	23	13
66.6% PbO_2	33.3% Zr	100	76	0

These tests indicate that potassium chlorate and lead peroxide are about equally efficient as oxidizers.

Production

Raw material will probably never be a limiting factor in the use of zirconium. It is encouraging to know that there are adequate and assured supplies of the ore for many years to come. Most of the ore is mined in Brazil and India but there are also commercial deposits in the United States which have produced several thousand tons. Both the silicate and oxide ores are relatively pure, the metal content ranging from 40% in low grade Zircon to 60% in high grade Baddeleyite. However, no simple method has yet been found to produce pure zirconium compounds from these minerals. The removal of iron and titanium is particularly difficult and expensive. Commercial zirconium dioxide can now be obtained in very pure form but unfortunately the price is relatively high due to the complex process which is used.

Almost all of the investigators have used some form of the thermit process to reduce zirconium compounds to the metal. The oxide and salts have been reduced by potassium, sodium, magnesium, aluminum and calcium. It is not possible to make the metal by reduction with either hydrogen or carbon.

Commercial zirconium metal is quite pure, containing less than 1% of metallic impurities. The chief impurity is zirconium dioxide, as each granule seems to be covered with a thin oxide layer.

Market Price and Packing

The present market quotation for zirconium metal powder is $6.00 per lb. in 100 lb. lots. It is usually packed in new, heavy kegs containing about 35 lbs. of the metal. As zirconium is quite inflammable when dry, large shipments are usually moistened with water and in this state it is inert and safe to handle.

Uses

The commercial uses of zirconium can be divided into two major classifications. The first group comprises various metallurgical uses for the powdered metal. The second group includes a number of fields in which zirconium is employed because it ignites at a relatively low temperature and burns rapidly with a high heat of combustion. At the present time this latter classification is the more important one.

Ammunition Primers

Zirconium is particularly adapted for use in ammunition priming compositions. The most conclusive proof of its excellence in this field is the fact that during the past two years a considerable percentage of the ammunition manufactured in the United States has contained zirconium metal. Several patents have recently been granted and several more are pending which cover the use of zirconium in primers. Its advantages for this purpose are listed below, as each one emphasizes a particular characteristic of the metal.

1. It ignites at a relatively low temperature, about 210° C., which is slightly above the ignition point of mercury fulminate.
2. It has a heat of combustion and flame temperature greatly in excess of any material heretofore used in primers. This makes it very efficient in igniting all types of propellant powders.
3. Zirconium seems to be the only sensitive, finely divided metallic element which does not deteriorate. It is stable in the presence of moisture and does not react with the other primer components. It will not form an amalgam with mercury and therefore does not decompose the mercury fulminate used in many priming compositions.
4. Although quite stable at ordinary temperature, zirconium is rapidly oxidizable when ignited. It burns so rapidly and with such heat that an addition of 5% zirconium in the priming composition frequently effects a marked reduction in "gun barrel time." Barrel time is the interval between the blow of the hammer and the departure of the bullet from the gun. One test showed:

   Barrel time without zirconium — 0.0036 second
   Barrel time with 5% zirconium — 0.003 second
   Reduction in barrel time — 16.7%

   Another test on a different primer composition gave this result:

   Barrel time without zirconium — 0.0051
   Barrel time with 5% zirconium — { 0.0046 / 0.0045
   Reduction in barrel time — 10.8%
5. Zirconium has marked friction sensitivity.
6. Zirconium, upon burning, produces an oxide which is chemically inert and non-hygroscopic so that it will not cause the corrosion or rusting of gun barrels.

A typical primer composition is given below:

Mercury Fulminate — 40%
Barium Nitrate — 30%
Antimony Sulphide — 20%
Zirconium Metal Powder — 4 – 10%

Flashlight Powder

We have already mentioned the use of zirconium in smokeless flashlight powder. This was first described in German Patent No. 336,004 which suggests the following composition:

9 grams Zirconium Metal
5 grams Barium Peroxide
6 grams Barium Nitrate

However, commercial flashlight powder usually has approximately this formula:

Zirconium Metal — 28½%
Magnesium Metal — 13½%
Barium Nitrate — 58 %

Electric Blasting Caps

The igniting composition in an electric detonator usually consists of mercury fulminate or lead azide mixed with an oxidizer such as potassium chlorate and a binder such as nitrocellulose. Many successful tests have been made in which zirconium was substituted for the mercury fulminate or lead azide. The advantages of using zirconium for this purpose are the same as those listed for ammunition primers. It has been used only to a limited extent in this field due to the danger in changing large scale manufacturing processes over to a new type of explosive composition.

Photoflash Lamps

The use of zirconium in this field has been described in the opening paragraph. A mixture of zirconium and lead peroxide is coated on a fine bridge wire and is ignited by the electric current.

Pyrotechnics

The employment of zirconium in smokeless flashlight powder suggested its use in other forms of pyrotechnics. It has been tested in various military and naval flares, in Very signals, in airplane landing flares, in movie flares and in commercial fireworks. A particularly promising field for zirconium is in tracer ammunition. It has the advantage of being quite stable in a moist atmosphere whereas both powdered aluminum and mag-

nesium deteriorate. Furthermore, it ignites easily, produces no smoke and gives a great deal of light. However, the price of zirconium metal is much higher than that of magnesium or aluminum and this has limited its use to special types of pyrotechnics.

Torpedos and Firecrackers

A considerable quantity of zirconium is used in penny torpedos. When mixed with an oxidizer such as barium nitrate, zirconium has sufficient friction and impact sensitivity to ignite explosively when the torpedo is thrown against a hard surface. Small boys want plenty of noise, and a zirconium torpedo gives it to them. Only half as much of the zirconium mixture is used and yet it produces a louder detonation than the standard torpedo composition. It is also considerably more reliable as it was difficult to control the impact sensitivity of the old mixture.

A new type of firecracker containing zirconium has recently appeared on the market. In this case, the zirconium and barium nitrate are ignited by a fuse and not by friction or impact. Zirconium is also used in several other noise-making novelties.

Zirconium Getters

Because of its high reactivity with gases, zirconium metal powder has been used on a small scale in vacuum lamps as a getter. At a moderately high temperature it flashes and cleans up traces of oxygen, nitrogen, hydrogen, carbon dioxide, water vapor and other common gases. Zirconium is also used in this field because of the vigorous manner in which it reduces and volatilizes many metallic compounds. Thus mixtures of zirconium and caesium dichromate are placed in evacuated radio or photoelectric tubes and the tube is heated. The zirconium flashes, releasing metallic caesium in the lamp.

Portion of the Zirconium Metal Refining Unit
Plant of Foote Mineral Company

Metallurgical Uses

Zirconium alloys readily with both copper and nickel and it is probable that its use in Monel, nickel silver and copper alloys will increase in the near future. One example of its present use in this field is in a complex nickel alloy which is used as the electrode for one brand of spark plugs. It has recently been tried in Monel metal to increase the ductility and tensile strength at lower working temperatures. In certain tests from .2% to 1% zirconium was added to the melt and analysis of the finished metal showed from .09% to .44% zirconium content. The results of these tests were said to be very satisfactory. The domestic manufacturer of zirconium metal made a number of zirconium-nickel alloys about a year ago and found that the two metals reacted rather violently.

Zirconium also alloys with silicon, aluminum, titanium, manganese and iron. This last alloy, ferrozirconium of ferrosilicon-zirconium, has been widely advertised and widely used as a scavenger in steel-making. Like its alloys, the pure metal is a vigorous reducing agent and deoxidizer. It has been used on a small scale to degasify a high melting alloy of platinum and other metals. It has also been employed in making aluminum-free metals by a thermit reduction of the oxides.

Zirconium Carbide Tools

Several manufacturers of sintered tungsten carbide cutting tools use small quantities of metallic zirconium. It is mixed with other powdered metals such as tungsten and cobalt and the mixture is then converted to a complex carbide. Zirconium carbide is quite hard and refractory but its principal value in the tool is said to come from its low heat conductivity. A small percentage of zirconium reduces the heat transmission to a considerable extent and suggests that zirconium may have value in other fields because of its heat insulating quality.

Chemical Resistant Metal

A number of possible uses for zirconium have been suggested and tested in this field. The metal powder can be hydraulically compressed into bars, plates or small shapes for acid-resistant and alkali resistant work but so far no commercial applications have been found. As it has a definite and controllable ignition point, its use as a temperature indicator in corrosive baths might be feasible. Zirconium metal powder has also been tested as a catalyst in hydrogenation and in the synthesis of ammonia.

Ductile Zirconium

This article is concerned only with the history, properties and uses of finely divided zirconium metal. This form of metal is not ductile and cannot be rolled or worked into sheets, wire or special shapes. Dr. J. H. DeBoer of Philips Radio, Holland, has developed a thermal decomposition process in which non-ductile zirconium metal powder is converted to zirconium tetraiodide and then decomposed to form a ductile rod of zirconium metal. This ingenious process is now operating on a commercial scale and it is possible to secure zirconium filaments, sheets, rods, spinneret cups and plates. A brief description of the chemical resistance of the ductile metal may interest a number of readers. Sulphuric acid will not affect ductile zirconium. In one test the metal was immersed in 68% sulphuric acid at a temperature of 72° C. and after 100 days the zirconium was still bright and was not corroded. There was no loss of weight during this period. The ductile metal is also resistant to alkalies. As a matter of fact, zirconium is, in this respect, far superior to other metals used in rayon spinnerets. It is not attacked by molten NaOH and is only slightly affected by molten KOH. A test was made by immersing it in 4 N alkali hydroxide at 72° C. and there was no loss of weight or brightness after 25 days. A more complete description of the physical and chemical properties of ductile zirconium is found in an article by Dr. J. H. deBoer.

Summary

There has been a steady increase in the industrial uses of zirconium during its short career as a commercial metal. Its unusual and desirable properties will probably suggest many other commercial applications.

Chromium-Nickel as a Corrosion Resistant Alloy

(Concluded from November issue)

by Robert J. McKay*

PART III. WORKING PROPERTIES

Forging

The high temperature properties of Inconel adapt it to the production of shapes regularly forgeable in steel. (Fig. 11.) The ordinary precautions as to low sulphur fuels, reducing atmospheres with completed combustion are to be observed as on all high nickel alloys. The major part of the work should be done between 2400° and 1850° F. Light working without tensile or bending stresses can be continued as low at 1600° F. but no work should be attempted between this point and 1200° F. because of low ductility. Below 1200° F. work can be done but should be classed as "cold work."

Rolling and Drawing

In usual production for rolling and forging, Inconel is chill cast into 14″x14″ ingots weighing 3,200 lbs. or 10″x10″ ingots weighing 1,000 lbs. Ingots are milled, chipped and thoroughly overhauled and hot forged into blooms. The heating temperature is about 2300° F.

Hot and cold rolled sheets and strip and hot rolled and cold drawn rods are produced following much the same practice as in steel. Also cold drawn tubes are produced according to steel practice with especial attention to dies and lubricants.

In cold press drawing of shapes the series of operations and product obtained are roughly parallel with steel practice. Good lubricants and dies are necessary. Heat treated chrome-nickel cast iron, chrome plated steel, or hard bronze dies are suitable for large work and tungsten carbide steel for small work. Power consumption is somewhat higher than in drawing Monel metal and nickel but not as high as the chromium iron alloys. Shapes can be drawn in a satisfactory range (Fig. 12).

Casting

The metal for Inconel castings (Fig. 13) is melted in the electric furnace. The charge is made up of electrolytic nickel and low carbon ferro chrome. Carbon content in the finished casting is kept below .5%, the usual mark aimed for being .25%. The metal is deoxidized with magnesium.

The molds should be made up of a strong open sand which generally should be dried before pouring the metal. Cores should be fairly soft and the core compound should be one that produces a minimum of gas. Risers should be heavy as shrinkage is high and ample provision to take care of this feature must be made. The metal should be poured fast and at the lowest temperature at which it will run easily and fill the mold.

Machining

The alloy is machinable both in the rolled and cast form. In its normal composition without modification for free machining considerable heat is generated in machining. High speed tools are used and should be carefully heat-treated and sharp. Low speeds are necessary for ordinary lathe work. For instance, where with ⅛″ cut and 1/32″ feed a speed of 70 ft./min. is suitable for Monel approximately two-thirds this speed would be right for Inconel. It machines uniformly and does not drag or stick badly. Sulphur base oil should be used as a lubricant.

Heat Treatment

A considerable range of strength and hardness properties are obtained by proper combination of cold-working and annealing. In its normal composition Inconel does not age-harden and cold-working is the only hardening process.

When heavily cold-worked only the slightest effects on the physical properties are observed in heating up to 1000° F. At about this temperature internal stresses begin to be relieved. They are almost completely relieved by heating 1½ hours at 1400° F. with only slight softening. Softening by annealing begins at about 1400°, is distinctly perceptible at 1600° F., and is reasonably complete in 10 to 15 minutes heating at 1800° F. Above this temperature grain growth is liable to be objectionable although very short heating at 1900° F. will cause complete softening without undue grain growth. The rate of cooling is unimportant as affecting the physical properties and either quenching or furnace cooling will produce proper softening. Quenching in water or dilute alcohol may aid the time control of annealing and will reduce oxidation somewhat.

The furnace atmosphere should be free from active oxygen and should be low in sulphur. Many oxygen compounds, including steam, will produce chromium oxide on Inconel surfaces and even the best atmosphere from the common fuels will produce some oxide. Such oxide is removable chiefly by grinding or pickling. In an atmosphere of dry hydrogen no oxide will be produced but such an atmosphere must be maintained at all times when the metal is over 700° F. to insure complete freedom from oxide. The oxide does not scale off.

Welded joints in Inconel are not subject to intergranular deterioration, and do not require heat treatment to bring out

*In charge of Technical Service on Mill Products, International Nickel Company.

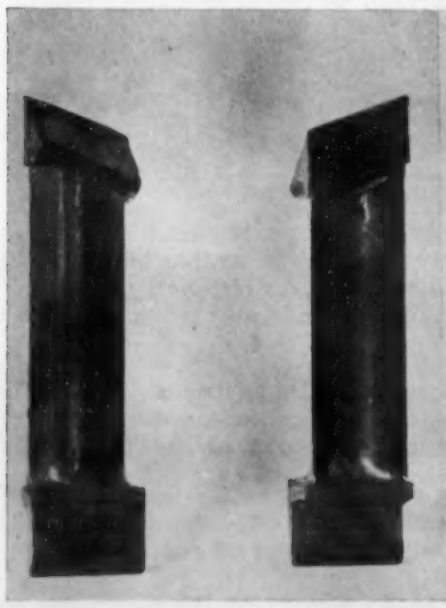

Fig. 11. Turbine Blading as Drop Forged.

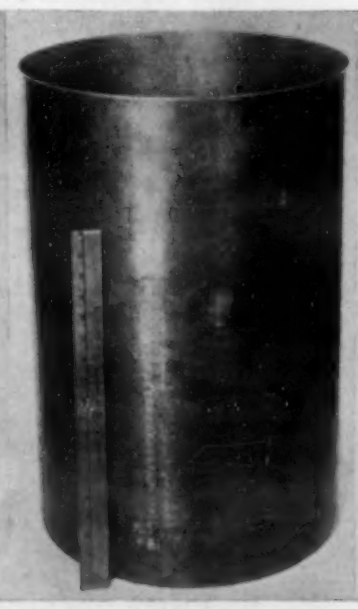

Fig. 12. Cylindrical Drawn Shape. Spun to Size.

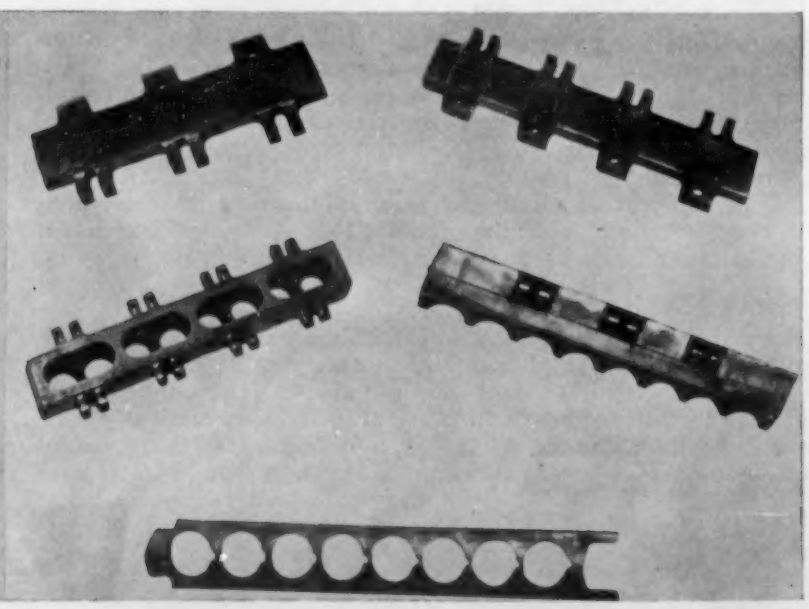

Fig. 13. Typical Header Castings for Milk Circulation unit.

best corrosion resistance. In fact an important characteristic of Inconel is its freedom from the deteriorating type of structure change associated in the case of some chromium-nickel-iron alloys with the heat of welding.

Pickling

The corrosion resistant properties are evident in this process and pickling must be done with active acids combined with oxidizing agents. Oxides are, of course, formed rapidly in the presence of free oxygen and less rapidly in atmospheres where oxygen is in combination with carbon. Oxide formed in an atmosphere containing free oxygen is more easily dissolved than that formed when the oxygen is in chemical combination, since the latter contains a higher percentage of chromium oxide. However, the heavier oxide of oxidizing atmospheres may leave a rough surface after pickling and, therefore, in most cases, the high chromium oxide is produced and must be removed. Hot solutions of dilute nitric acid with the presence of fluorides or chlorides are reasonably effective. Scrubbing the surface during pickling produces more rapid effects and therefore smoother pickling. Paste pickles have been found very useful in handling large plates or where equipment is not available for handling these very corrosive liquids. For such work a mixture of 1 part lampblack, 10 parts Fullers' earth, 25 parts 20° Be' HCl and 2 parts cupric chloride is a good one.

Joining

The facility with which this alloy may be joined is very useful to the fabricator. Practically any of the standard joining

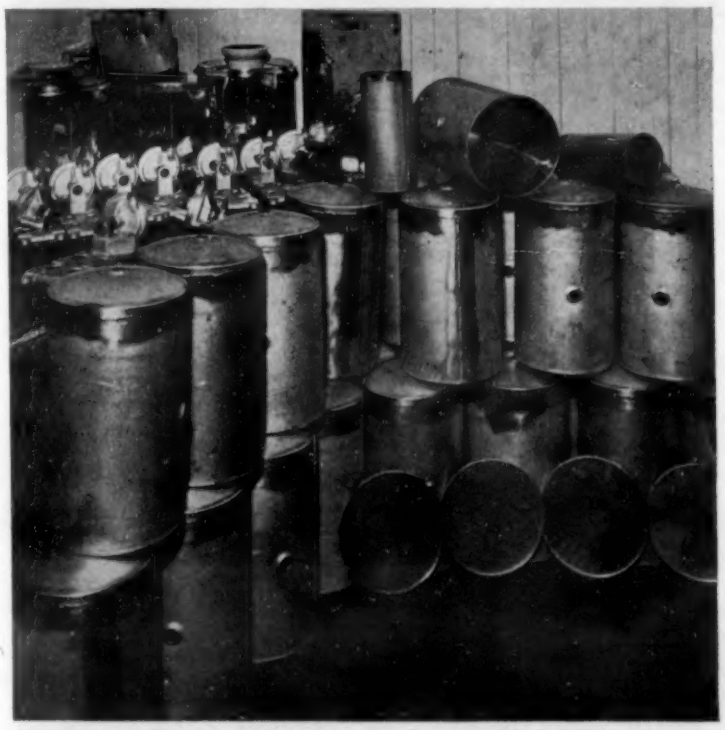

Fig. 14. Metallic Arc Welded Orange Juice Containers 12" diameter 0.050" wall.

methods, lock seaming, riveting, bolting, soldering, silver soldering, brazing and welding are readily accomplished.

The facility of welding is particularly interesting in that electric arc welding is easier and produces better results than on pure nickel. Sheet metal of 18 gage and heavier can be readily arc welded. (Fig. 14.)

In the table below are given the results of tensile tests on welded joints in Inconel:

Table VI. Physical Properties of Metallic Arc Welds on 1/8" Sheet

Type of Weld	Breaking Strength—lbs. per sq. in. Broke in plate	Elongation across fracture %
Unwelded sheet	96,000	47.8
As welded	97,200	31.7
Machined	95,625	34.5

The quality of the weld metal is expressed by the values for dressed welds, in which the weld was machined on both sides not completely flush with the plate. Even in these tests the greater number of fractures occurred in the plate.

The values for the raw metallic arc welds give the strengths obtainable from the joint as a whole, such as would be encountered in practice.

The ductility of welds has been tested thoroughly in bend tests, with the bend across the weld. No fractures occur even when the specimens are hammered back to back along the entire length.

Oxy-acetylene welding (Fig. 15) also produces strong ductile welds. Bare rods are used with a slightly reducing flame or, if oxidation is to be prevented, a flux mixture of boric acid, borax and sodium fluoride is used.

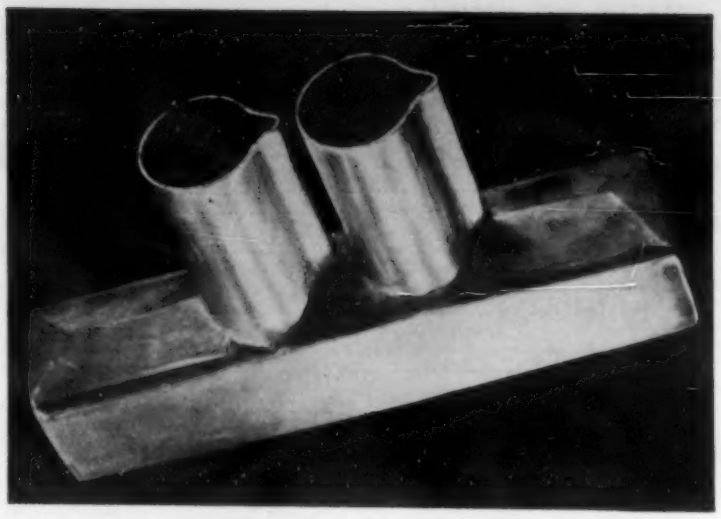

Fig. 15. Milk Cooler End Detail, Welded and Solder Filleted.

Automatic gas welding is well adapted to the production of tubing. By this process tubing is made which is welded completely through but lies flat on the under surface with no projection or "bead." Such tubing can be annealed, drawn, swaged and bent without failure. It approaches the soundness of seamless tubing and is superior to it in uniformity of wall thickness, surface finish and freedom from die scratching or adhering foreign metals.

All ordinary hand gas welding operations, such as flange or edge welding and butt welding of sheets, welding of round sections for chain, etc., are readily accomplished.

Spot and electric seam welding give strong and durable results. "Shot" welding is satisfactory but not necessary to prevent deterioration.

Brazing and silver soldering with the use of the oxy-acetylene torch are useful for joining where the higher temperatures of fusion welding produce buckling or other undesirable effects. This work is usually done with the use of a flux of the same ingredients as are used for gas welding. Joints are usually designed so that the slightly lower physical properties of the filling metals do not produce low structural strength. For instance, a sleeve joint is recommended in tubing with sufficient lap to give adequate strength to the soldered joint. The different corrosion resistance of the brazing or silver soldering materials should be considered in designing such joints. For invisible joints, a nickel bearing brazing rod, such as Oxweld No. 20, is necessary for color matching, or a white silver solder, such as Handy & Harman's RT solder. The high copper brazing materials are not as resistant to many types of corrosion. Properly designed joints are not liable to be seriously weakened mechanically from this cause, but may become visible in time if exposed to corrosive atmospheres or foods without frequent cleaning. Silver solders are tarnished easily by sulphur compounds and neither type of joint can be expected to retain a brilliant lustre as long as Inconel itself. Brazing compounds should have a relatively high melting point, as with Oxweld No. 21 (or No. 20 for white brazing), and silver solders should have a low flow point to insure freedom from cracks which may occur during cooling if molten metals are in contact in the range 1600° to 1400° F.

Fig. 16. Soldering Practice, Milk Unit.

Soft soldered or lead filleted joints are useful, for instance in sanitary corners in dairy and chemical equipment (Figs. 15 & 16) and for work where even brazing temperatures are too high. The joints have the usual properties of soldered joints. Thorough bond with the metal must be insured by care, usually by "tinning" with an iron, and the more active fluxes, such as Spear's Soldering Fluid* and Johnson's Soldering Fluid** are recommended.

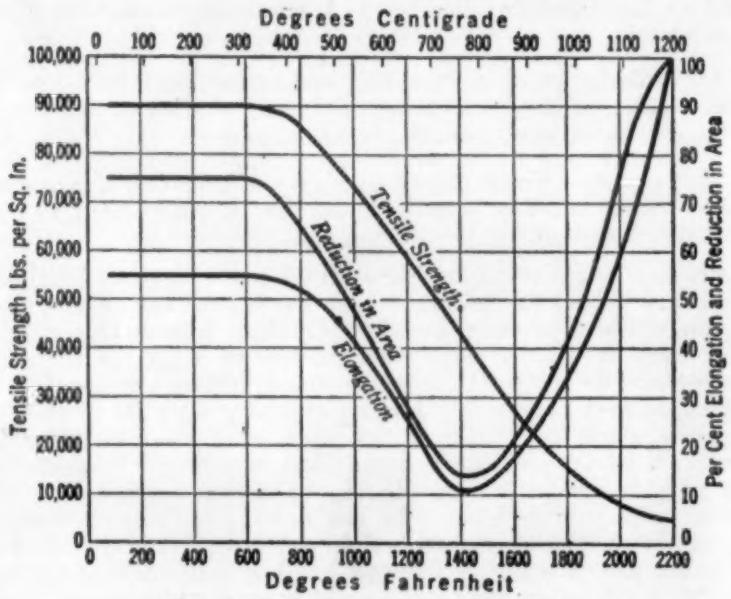

Fig. 8. High Temperature Properties

Inconel is one of the nickel-chromium group of alloys that has the highest resistance to oxidation at high temperature, and as well, the highest degree of strength in the elevated temperature range. It furthermore has the important property of being free from intergranular deterioration in the high temperature range.

The tensile properties of annealed Inconel at elevated temperatures are given in Fig. 8.

Strength tests [Tapsell and Bradley, Eng'g. Vol. 120 (1925) 614-615] made on an alloy (unannealed) closely similar to Inconel gave the curves of Fig. 9.

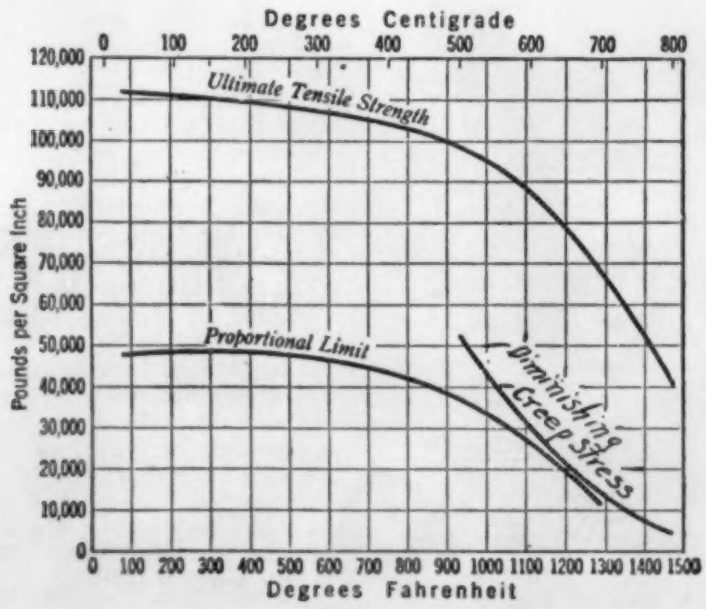

Fig. 9.

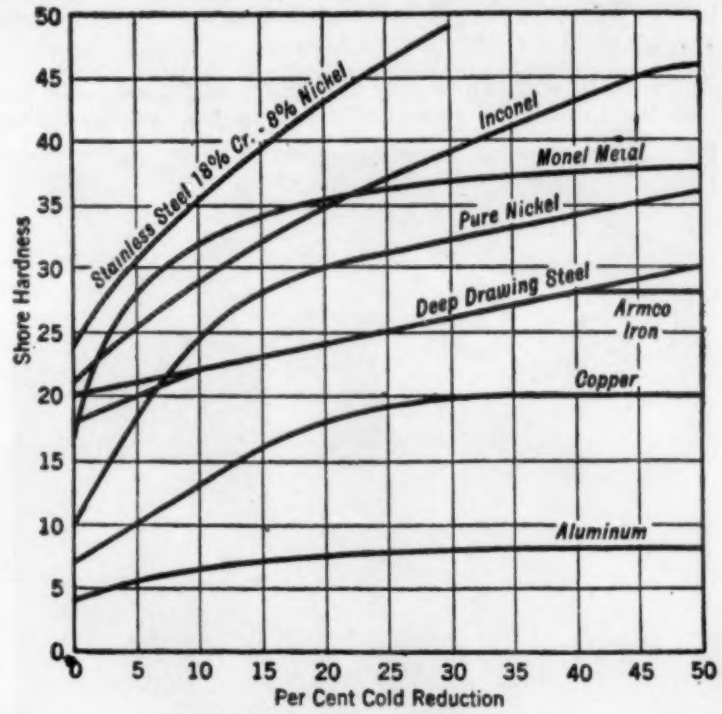
The creep tests were made by observing the stretch of a series of specimens held at a single temperature but under different loads. The stresses were so chosen that the higher stresses caused fracture over a period of time, and the lower stress would not cause determinable creeping at the end of a 50-day period. From these results the authors estimated the stress at a given temperature which would not cause continuous creep. The curve given shows this value as it varies with temperature. Certainly the results are useful as indications, if not as accurately established values.

Impact Toughness

Impact tests made on Inconel specimens using the Charpy test ing machine, gave results averaging 200 ft.-lbs. Even with energy absorption of this high order the specimens failed to fracture. These results indicate a toughness that ranges considerably higher than the steels and higher than other non-ferrous alloys.

TABLE VIII. Erickson Ductility

	Depth of cup at fracture—in.	Bean load at fracture lbs.
7/8" ball and 1" vertical side mandrel	.470	13,500
7/8" ball and 1 1/8" tapered side mandrel	.550-.600	



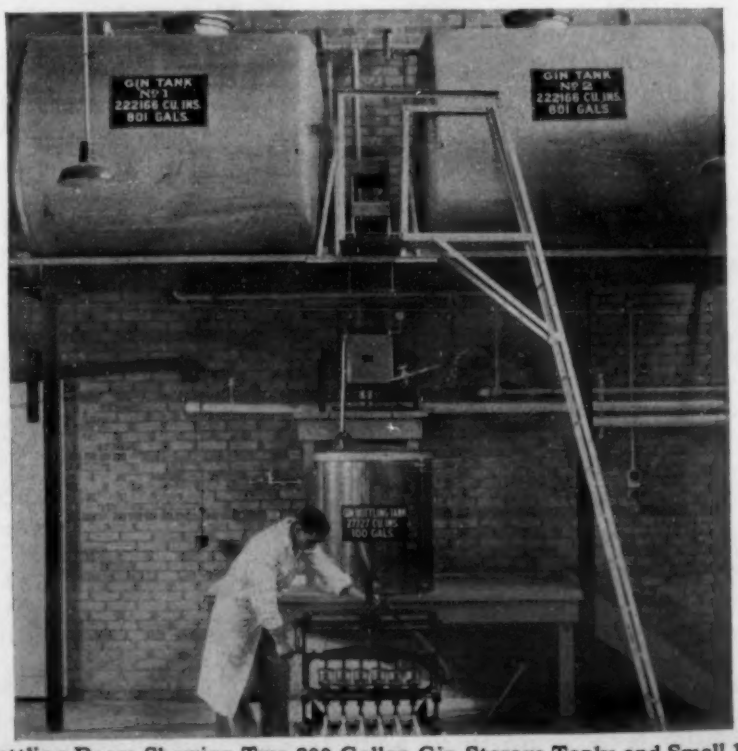


Fig. 10. Hardening with Cold Rolling

The combination of high physical properties, wide corrosion resistance, ease and variety of fabrication methods, and freedom from intercrystalline deterioration by heat or corrosion it is believed make the availability of this metal in the usual shapes a useful advance in engineering.

Bottling Room Showing Two 800 Gallon Gin Storage Tanks and Small 100 Gallon Bottling Tank. Storage Tanks are Inconel, Bottling Tank is Nickel.

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Sixty section editors and abstractors cover over 700 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstract appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important.

Note:—The markings between the columns of abstracts will be there each month from now on. When the next index is made the references will be to tenths of pages, right or left, and the rule will simplify finding the material desired.

The readers of METALS & ALLOYS will be interested to know that 5234 abstracts appeared in Current Metallurgical Abstracts in Vol. III of METALS & ALLOYS. As mentioned above the service now covers over 700 publications. An effort is made to have each abstract present the data appearing in the original article. The length of the abstract permits presenting all essential information, as the average number of words per abstract is 160 words. For most purposes the reading of the abstract can substitute for reading the article.

PROPERTIES OF METALS (1)

Magnesium. J. A. Gann. *Metal Progress,* Vol. 21, Apr. 1932, pages 33-38, 48.

The author traces the development of the use of Mg and its preparation during the last 20 years in which time the price has been reduced from $5.00 to $0.30 per pound. The present process of manufacture consists of electrolysis of $Mg Cl_2$ dehydrated in an atmosphere of HCl gas. The metal so produced has the following analysis, Al 0.022%, Fe 0.034%, Si 0.012% and Mg 99.93%. A table gives the properties of various Mg alloys. WLC (1)

Mechanical Properties of Nickel Wires. C. E. Ransley & C. J. Smithells. *Institute of Metals, Advance Copy* No. 615, Sept. 1932, 12 pages.

High-purity Ni was prepared by redepositing electrolytic Ni in a chloride bath and melting in H. Wires were prepared from commercial Ni (99.39%), refined Ni (99.91%), Ni plus 0.34% Mn, Ni plus 0.07% Mg, and Ni plus 2.33% Fe. Most of the wires tested were 0.0423″ in diameter. Softening tests were made by tensile tests of samples annealed at temperatures up to 1000° C. Recrystallization temperatures of wires reduced 75% by cold drawing were 480° C. for refined Ni, 580° C. for the Fe alloy, 620° C. for the Mn alloy, 640° C. for the Mg alloy, and 640° C. for the commercial Ni. High annealing temperatures resulted in low elongation values in some wires due to the formation of grains occupying the entire cross section of the wire. Creep tests in which the time to fracture with a given load at temperatures between 600° and 1000° C. were made. The curves obtained were similar to those obtained by other creep-test methods. JLG (1)

Oxidation-Reduction Potentials. LV. The Determination from Equilibrium Data. B. Ferric-Ferrous Electrode. Stephen Popoff, Vernon B. Fleharty & Edwin L. Hanson. *Journal American Chemical Society,* Vol. 53, May 1931, pages 1643-1651.

The oxidation-reduction potential of the ferric-ferrous electrode has been calculated from the equilibrium constant and found to be —0.7473v. This value based on a chemical study is in agreement with —0.7477v. as found previously by the same authors using the e. m. f. method. MEH (1)

The Photoelectric Properties of Silver. Ralph P. Winch. *Physical Review,* Vol. 37, May 1931, pages 1269-1275.

Ag was carefully outgassed and its photoelectric properties were studied during outgassing and after stable conditions were reached. An outgassing curve is plotted for 1200 nours of heat treatment before final readings were taken. For thoroughly outgassed Ag curves are plotted showing photoemission as a function of temperature for fixed wave lengths of incident light. These curves show that for wave lengths near the long-wave limit there is a marked increase in emission with temperature; for wave lengths farther away there is no change with temperature; and for wave lengths still more remote there is a slight decrease in emission with increased temperature. Curves for emission per unit of incident light intensity as a function of wave length show that the long-wave limit at 600° C. is 2700 ± 20 A. U. while at room temperature it is 2610 ± 30 A. U. WAT (1)

The Diamagnetism of Bismuth. S. Ramachandra Rao. *Indian Journal of Physics,* Vol. 7, Part I, Apr. 1, 1932, pages 35-42.

Colloidal Bi when melted and recrystallized shows an increase of diamagnetic susceptibility. This result confirms the observation that the susceptibility decreases with decreasing particle size. Attention is drawn to the work of Goetz (*Proceedings National Academy of Science,* Vol. 16, 1930, page 99; *Physical Review,* Vol. 38, 1931, page 2075) who found that a microscopic structure is superposed on the lattice structure of Bi crystals. There probably exists a relation between this mosaic and the variation of the diamagnetic susceptibility with particle size. 18 references. GN (1)

The Nuclear Moment of Se^{80}. (Das Kernmoment von Se^{80}.) K. Wurm. *Die Naturwissenschaften,* Vol. 20, Jan. 1, 1932, page 85.

The Se-band spectrum in the blue range of the visible spectrum and in the adjacent ultra-violet range has been taken with a large prism spectrograph for the following wave range: $\lambda = 4000 — 4200$. Based on his measurements the writer concludes that Se^{80} has no nuclear moment. EF (1)

Magnetic Materials in the Year 1931. T. D. Yensen. *Engineering,* Vol. 133, Feb. 19, 1932, page 235.

Abstract of paper read before the American Iron and Steel Institute, New York, October 23, 1931. See *Metals & Alloys,* Vol. 3, May, 1932, page MA 115. LFM (1)

Corrosion Proof Aluminum. (Korrosionsbeständiges Aluminium.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, May 1, 1932, page 239.

The properties of a new highly corrosion resistant Al alloy which has recently been developed in Germany are described. Its applications for many purposes are given. The alloy probably will replace pure Al in many instances. The new alloy is known in Germany under the symbol A W 15. GN (1)

Contributions to the Physical Chemistry of Rhenium. (Beiträge zur physikalischen Chemie des Rheniums.) W. A. Roth & G. Becker. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 159, Mar. 1932, pages 27-39.

The heat of formation of Re_2O_7 at 20°C. and constant pressure amounts to 295.5 ± 2 kcal and the heat of formation of Re_2O5 is 169 kcal. The following value was computed for $KReO_4$: + 262 kcal. Determinations on the solution heats yielded the following data: $KReO_4$: at 16.7°C. = — 13.93 ± 0.03 kcal and at 21.7°C. = — 13.80 ± 0.03 kcal. $KReO_4$ is a very strong acid and the saturation concentration at 18°C. is 0.0329 N. 10 references. EF (1)

Selenium in Canada. *Canadian Mining Journal,* Vol. 53, June 1932, page 249.

Se was first produced in Canada early in 1931. It is generally sold at $1.80-2.00/lb. in the form of an amorphous powder, or as small rods and buttons. WHB (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Improvements in Non-Ferrous Metals and Alloys for Chemical Engineering Purposes. *Industrial Chemist,* Vol. 7, Nov. 1931, pages 435-437.

12 references. Requirements are (1) suitable mechanical properties, (2) resistance to corrosion and (3) weldability. Interest was shown in a recently developed Cu alloy with an elastic limit of 4 or 5 tons/in.². The overcoming of manufacturing, as well as welding difficulties is making Al bronze more desirable. Everdur and P.M.G. are the most noteworthy of the Cu-Si alloys. A new Ni-clad steel plate offering corrosion-resisting and high strength properties is still in the development stage. The advantages of Ag, Pb and Ta as well as Al and some of its alloys, are discussed. Mechanically incorporating small particles of foreign metals such as Ag, Bi or Fe into the surface of Pb sheet has been found to increase the resistance of Pb to corrosion. Alloys for high temperature service and electrodeposited coatings are also discussed. RAW (2)

Aluminium Alloys and Their Heat Treatment. *Metallurgist,* May 1931, pages 67-69.

Extended abstract of a paper by M. J. Suhr. See "Thermal Treatment is Indispensable for Aluminum and Light Aluminum Alloys," *Metals & Alloys,* Vol. 2, May 1931, page 95. (2)

Aluminium-Silicon Alloys as Piston Materials. *Engineering,* Vol. 133, Feb. 5, 1932, pages 172-173.

Outlines the various properties of Al-Si alloys which make them suitable for pistons. By proper heat treatment the Brinell hardness of Y-alloy can be increased from 80 to 125. The high thermal conductivity, the low density which is the lowest of all commercial Alloys, and the very low coefficient of linear expansion of these high-Si Al alloys are excellent properties for piston materials. LFM (2)

Properties and Composition of Sand-Cast Aluminum Alloys. *Machinery,* Vol. 38, Nov. 1931, page 200A.

Table and brief notes compiled by the High Pressure Tank Car Dept. of General American Tank Car Corp. RHP (2)

Magnesium Alloy Finds Varied Uses in Germany. *Iron Age,* Vol. 128, Nov. 12, 1931, page 1240.

Mg alloys are widely used by German aircraft manufacturers in motors, wings, fuselage and for interor furnishings. The alloy mostly used is the elektron developed in Germany in 1909. Elektron has a specific gravity of 1.8, melting point of 625°-650° C. and electric conductivity of 12-18. Tensile strength ranges from 14,000 to 31,000 lbs./in.² for castings and 35,000 to 60,000 lbs./in.² for rolled material. Brinell hardness is from 45-70. VSP (2)

A New Light Alloy. *Engineer,* Vol. 153, Jan. 15, 1932 page 70.

The new alloy described is called "MG 7" and is made by James Booth and Co., Ltd., of Birmingham, England. The alloy is composed mainly of Al in combination with Mg and Mn. Exact composition is not given. Its principal physical properties are: specific gravity 2.63, annealing temperature 380° C., forging temperature 400-420° C., fatigue range ± 9.5 - ± 10.25 tons/in.², Brinell hardness 90-115, Izod impact value 17 ft.-lb. As the metal cannot be heat treated, changes in strength must be brought about by varying amounts of cold work. It has a very considerable toughness, can be shaped satisfactorily and since it contains no Cu it can be welded. It is resistant to atmospheric and sea-water corrosion and is entirely free from liability to intercrystalline corrosion. See also *Metals & Alloys,* Vol. 2, Oct. 1931, pages 238-239. LFM (2)

Magnesium and Its Alloys. *American Machinist,* Vol. 75, Nov. 19, 1931, pages 795-796; Nov. 26, 1931, page 833.

Briefly summarizes some information on properties, alloy composition, strengths, casting, heat-treating, forging, machining and working, welding and surface treatment and finishing. RHP (2)

Some Attempts at Making Beryllium-Magnesium Alloys. Ronald J. M. Payne & John L. Haughton. *Institute of Metals, Advance Copy* No. 614, Sept. 1932, 2 pages.

Several methods for preparing Be-Mg alloys were tried without success. JLG (2)

Nickel Alloys and their Application (Nickellegierungen und ihre Verwendung.) A. Pauwen. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 65, Apr. 10, 1932, page 49

The paper deals with the properties and the use of Ni case carburizing steels, Ni bronzes, and Ni-Al. GN (2)

Iudustrial Alloys of Copper. Reginald G. Johnston. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 55-57.

Brief mention is made of Cu rich alloys, their physical properties and exceptional uses. PRK (2)

The New Aluminum Light Alloy "Chlumin." (Die neue Aluminium- Leicht- Legierung "Chlumin.") W. Keil. *Zeitschrift für Instrumentenkunde,* Vol. 52, Aug. 1932, page 377.

Abstract of a paper by I. Iitaka in *Journal Society of Mechanical Engineers* of Japan, Vol. 33, 1930, pages 203-208. The new Al alloy contains Cr and small amounts of Mg and Fe. Density: 2.71. It is used in cast and rolled state. The mechanical properties are similar to duralumin. The corrosion resistance against sea water is claimed to be superior to any other known Al light alloy. Chlumin is more readily machinable than duralumin. GN (2)

Aluminum-silicon-magnesium Casting Alloys. R. S. Archer & L. W. Kempf. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 448-479.

See *Metals & Alloys,* Vol. 1, Dec. 1930, page 898. (2)

The Heat-Treatment of Non-Ferrous Metals. D. Hanson. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 83-85, 108.

The recent improvements in physical properties of nonferrous alloys, obtained by combinations of cold working, age-hardening, and heat treatment, are discussed. PRK (2)

Ordinary and Special Bronzes. (Les Bronzes Ordinaires et les Bronzes Speciaux.) Leon Guillet. *Cuivre et Laiton,* Vol. 5, May 30, 1932, pages 223-225.

The influence of quenching on the quality of bronzes is discussed; a quenching temperature of about 600°-650° C. gives a maximum of tensile strength and elongation in almost all bronzes with 5 to 20% Sn. Annealing after quenching increases the hardness, but this method seems to be practiced only for musical percussion instruments; the author recommends it also for industrial processes. Ha (2)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Recent Developments in Corrosion Prevention of Ferrous Metals. V. V. KENDALL & F. N. SPELLER. *Industrial & Engineering Chemistry,* Vol. 23, July 1931, pages 735-742.

Presented before the Western Metal Congress, San Francisco, Calif., Feb. 1931. 28 references. This is a review of the principal outstanding developments in corrosion work during the past 2 years, and is treated under the following heads: film formation in relation to physical properties, potentials and continuity; atmospheric corrosion; methods of testing corrosion; underwater corrosion; reconditioning of water pipes and water-cooling apparatus; steam boiler problems; soil corrosion; and corrosion in the oil industry. MEH (4) 1

Some Recent Papers on Corrosion Research. (Einige neuere Beiträge zur Korrosionsforschung.) E. H. SCHULZ. *Stahl und Eisen,* Vol. 52, June 23, 1932, pages 614-616.

Summary of recent literature on corrosion research. 10 references. DTR (4) 2

Coöperation in the Fields of Corrosion and Corrosion Protection. (Gemeinschaftsarbeit auf dem Korrosions-und Korrosionschutzgebiet.) *Farben Zeitung,* Vol. 37, Nov. 7, 1931, page 200.

4 leading German Engineering and Chemical Societies held the first corrosion meeting in Berlin. Among the papers presented, 2 are reviewed in the present article: E. Groos, "Causes, Manifestation and Extent of Corrosion and Corrosion Prevention in Ship Building," and W. Krumbhaar, "On Application of Coatings as Corrosion Protection." In the latter the speaker largely refers to American experiences. EF (4) 3

Safety in the Chemical Industry. J. DAVIDSON PRATT. *Journal Society of Chemical Industry,* Vol. 51, May 13, 1932, pages 420-427.

The subject is divided into the main headings of fire and explosive risks, gassing risks and corrosive risks. Consideration is also given to design and layout of plant. VVK (4)

Products of Corrosion of Steel. Factors Determining Their Composition and Its Influence on Rate of Corrosion in Oxygenated Water. H. O. FORREST, B. E. ROETHELI & R. H. BROWN. *Industrial & Engineering Chemistry,* Vol. 23, June 1931, pages 650-653. 4

The corrosion products having a major influence on ultimate corrosion rates are gelatinous ferric hydroxide and granular magnetic oxide of iron; the former, under the conditions in which it is formed, is very resistant to the diffusion of oxygen and the various ions present, while the latter is essentially non-resistant. The influence of pH on the character of the precipitated film is discussed. MEH (4)

The Protection of Iron and Steel From Corrosion. Part I.—The Principles of Protection. ERNEST S. HEDGES. *Metallurgia,* Vol. 6, July 1932, pages 87-89.

Deals with action of O and behavior of Fe anodes. JLG (4) 5

Equilibrium in the Iron-Oxygen-Hydrogen System at Temperatures above 1000° C. WALTER E. JOMINY & DONALD W. MURPHY. *Industrial & Engineering Chemistry,* Vol. 23, Apr. 1931, pages 384-387.

A method for the determination of the iron-iron oxide-hydrogen-water equilibrium at various temperatures has been developed in which a gaseous mixture of H and water vapor is allowed to flow past a sample of metallic Fe. The ratio of H to water vapor is controlled so that the mixture will be either oxidizing or non-oxidizing to the Fe and at any temperature the true equilibrium ratio will lie between the closest oxidizing and non-oxidizing points. The equilibrium data when plotted show a break in the curves at about 1357° C. which may be taken as the melting point of the ferrous oxide. 16 references. MEH (4) 6

On the Galvanic and Potentiometric Determination of the Corrosion Process (Über die galvano- und potentiometrische Bestimmung des Korrosionsvorganges.) M. TH. MICHAILOFF. *Korrosion und Metallschutz,* Vol. 8, Apr. 1932, pages 85-89.

Opens with a discussion of the various factors playing a significent role in corrosion and deals at some length with the galvanometric testing methods. Experiments with 3 grades of cast Fe (no analyses given) in 87, 92, and 97% H_2SO_4 at 20°, 60°, 90° and 300° C. were carried out with the object of discovering some relationship which would furnish a corrosion rate criterion. A ground cast Fe rod with a newly prepared surface is immersed into the acid in connection with a Pt-electrode. The e.m.f. rapidly drops as can be seen from the diagrams accompanying the paper. After 30-50 min. a characteristic value is attained which could be reproduced with the same kind of sample. An almost constant e.m.f. value was determined for each acid concentration and at each temperature. Further testing results are compiled in tables which prove that the rate of dissolution at various temperatures and acid concentrations is not proportional to the e.m.f. although the same material was employed. No correlation of the maximum current density to the corrosion degree (average thickness of layer dissolved during one month) could be established at different temperatures and concentrations of the corroding medium. Different testing samples submitted to the same testing conditions also did not yield a relation between the dissolution speed and maximum current density. The writer concludes that the galvanometric principle involved in Tödt's Corrosimeter does not hold true for Fe tested in H_2SO_4 of high concentrations and therefore strongly advises to directly determine the losses in weight instead. EF (4) 7 8 9

The Corrosion Problem. II. Iron. (Zur Korrosionsfrage. II. Eisen.) E. NAUMANN. *Gas und Wasserfach,* Vol. 75, May 7, 1932, pages 349-351.

Three types of Fe corrosion are discussed: uniform destruction of the surface, local attack, corrosion of cast Fe (sponginess). The corrosion in the interior of water pipes is then discussed. CO_2 and O are of the greatest importance. All other substances contained in water range next in importance as to their significance for causing corrosion. The corrosion of the outside surface of pipes (effect of the soil) is discussed with reference to the substances contained in the soil, the underground water, and stray electric currents. The remedies are considered: suitable composition of the pipe material, surface coating, purification of the water, special measures in the soil. GN (4) 10

DURIRON
AND
DURIMET
FOR
Corrosion Resistance

DURIRON is a high-silicon iron more universally resistant to acid corrosion than any other commercially available alloy. Duriron is very hard, strongly resistant to abrasion and scouring, and is of the same quality and properties throughout. It is practically unaffected by sulphuric, nitric, acetic and most other commercial acids, at any strength or temperature.

Duriron is procurable in a wide range of cast forms for the handling of corrosives, both gas and liquid. Pumps, valves, pipe, fittings, fans, and such general equipment are made of Duriron, as well as much special equipment to suit individual requirements.

DURIMET

DURIMET is a high nickel-chromium-silicon steel possessing great resistance to many corrosives, especially sulphuric acid at the lower concentrations at all temperatures. Durimet is stronger than mild steel, and at high temperatures, has greater strength and does not scale.

DURCO NIROSTA ALLOYS

DURCO NIROSTA KA2S and KA2SMo are 18/8 alloys of low carbon content (below .07%). The low carbon is assurance against intercrystalline corrosion.

Consultation Invited

The Duriron Company has had twenty years of experience in the manufacture of corrosion-resisting materials. Consultation on problems of this nature is invited. Bulletin No. 150 describes Duriron and Bulletin No. 171 gives the chemical and physical characteristics of corrosion-resisting steels. These will be sent upon request. Write THE DURIRON COMPANY, Inc., 432 No. Findlay St., Dayton, Ohio.

Thermodynamic Investigations of the System Iron-Carbon-Oxygen. (Thermodynamische Untersuchungen zum System Eisen-Kohlenstoff-Sauerstoff.) H. DUENWALD & C. WAGNER. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 199, No. 4, 1931, pages 321-346.

The equilibrium of CO_2 (gas)+C (dissolved in γ Fe) = 2 CO (gas) was investigated between 940° and 1070° C. The saturation concentration of C in α-Fe was determined to about 0.008%. The tests show that the solubility of O in α-ferrite and γ-ferrite is smaller than 0.01% at both 800° and 1000° C. The method of measuring the equilibria by means of an electromagnetic balance is described. Ha (5a)

Optical Hints for the Metallographer. L. V. FOSTER. *Heat Treating & Forging,* Vol. 18, Mar. 1932, pages 201-202; Apr. 1932, pages 265-266.

Discusses magnification, curvature of the field, resolving power and use of filters. MS (5a)

A Study of Aluminum-Iron-Chromium Alloys. (Contribution à l'étude des alliages aluminium-fer-chrome.) CH. TAILLANDIER. *Revue de Métallurgie,* Vol. 29, June 1932, pages 315-325; July 1932, pages 348-356.

A comprehensive study of Al-Fe-Cr alloys prepared from commercially pure metals. A series of 9 alloys was investigated containing 0.42%-2.29% Cr, 0.74%-4.18% Fe, 0.12%-0.21% Si. Thermal and metallographic analysis indicated the presence of a ternary eutectic point around 2% Cr and 1% Fe. The second modification of Al above 560° C. was not found and could probably be attributed to the presence of Si. With Fe and Cr content greater than 5%, the solidus-liquidus range prevents the production of a uniform cast alloy. Resistance study established the presence of a ternary solid solution. Only alloys with less than 2-2.5% Fe and Cr appear to be of interest. JDG (5a)

Structural Changes in Annealing of Mild Steel. (Gefügeänderungen beim Glühen von weichem Stahl.) W. BRENSCHEIDT. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns,* Vol. 1, July 1931, pages 127-139.

If commercial Fe is subjected to annealing of longer duration in an atmosphere of oxidizing gases the edges are decarburized and the grains sometimes grow and assume a pillar or column-like appearance, if tensions and C are present. The greatest columns are formed at 3% deformation, at 6% the formation ceases. The conditions of these formations are discussed in detail on the basis of the experiments and the results illustrated. Ha (5a)

The Solubility of Aluminium in Magnesium in the Solid State at Different Temperatures. P. SALDAU & M. ZAMOTORIN. *Institute of Metals, Advance Copy* No. 596, Mar. 1932, 5 pages.

1 Determined the solid solubility of Al in Mg by microscopic examination of heat-treated specimens. The Mg was 99.68% pure. The solubility was found to be 12.6% at the eutectic temperature of 436° C., 10.9% at 400° C., 6.08 at 300° C. and constant below 300° C. Although the solubility was apparently constant below this latter temperature, this was thought to be somewhat improbable. The particles precipitated at low temperatures may have been too small to be visible in the microstructure, or the time of annealing may have been too short to allow complete precipitation. Results of other investigators are discussed. 3 references. JLG (5a)

The System Gold-Mercury. (Das System Gold-Quecksilber.) I. N. PLAKSIN. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, page 89.

2 The results of thermal analyses of Au-Hg alloys is expressed in a constitutional diagram. 2 compounds are present, Au_2Hg and $AuHg_2$, both melting with a peritectic reaction, at 402° (420°?) and 310° C. resp. The approximate solubility of Hg in solid Au is 17%; solid Hg shows no solubility for Au; the 2 metals are completely miscible in the liquid state. Besides 2 peritectic points the system shows a eutectic on the Hg side with only a trace of Au; the eutectic temperature is 0.1° below the freezing point of Hg. RFM (5a)

The Transformation of Austenite Below the Critical Range. J. M. ROBERTSON. *Carnegie Scholarship Memoirs, Iron & Steel Institute,* Vol. 20, 1931, pages 1-64.

3 44 references. The author gives a theoretical discussion of prior work on the decomposition of austenite touching upon the different definitions of martensite held by various investigators. The tetragonal structure of martensite between the α and γ lattice structures is discussed. A series of 8 steels from 0.10% to 1.73% C have been examined after various quenches with varying rates of cooling from which the mechanism of the various changes is developed. It is shown that for a given C content there is a definite temperature at which martensite begins to form on cooling. Martensite forms while austenite is being cooled; it is practically stable at constant temperature. WLC (5a)

The System Iron-Cobalt-Molybdenum. (Das System Eisen-Kobalt-Molybdän.) WERNER KÖSTER & WILLI TONN. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 627-630.

Report of Research Institute of Vereinigte Stahlwerke, A.-G., Dortmund. In amounts of Mo equal to those represented by the section Fe_3Mo_2-CoMo, the 3-phase system Fe-Co-Mo was investigated from a thermal, dilatometric microscopic basis. Up to the equilibrium concentration the data shows fairly good agreement with the phase diagram of the Fe-Co-W alloys. The 2 compounds Fe_3Mo_2 and CoMo form a continuous series of δ- Solid Solutions, duplicating those formed with W. The ternary α- and γ- Solid Solutions precipitate out, and a ternary eutectic could not be found. The eutectic equilibrium of the border systems Fe-Mo and Co-Mo as well as the peritectic equilibrium in the phase system Fe-Co were all lowered by addition of the third element and at 1300° C. establish a 4-phase equilibrium: melt + α-solid solution $\rightleftarrows$ γ-solid solution + δ-solid solution. From this proceeds two 3-phase equilibriums, of which one results in a decomposition: melt = γ-solid solution = CoMo; while the other: α-solid solution = γ-solid solution + δ-solid solution, determines predominantly the transformations in the solid state. The range of concentration in which the α- γ- conversion occurs, was determined closely. Studies on precipitation or separation hardness show that the annealing temperature, at which the maximum hardening is produced, varies with the structural components of the alloy. In the partial system, CoMo-Fe_3Mo_2 still more solid solution of FeMo and Fe_3Mo_2 or CoMo were observed, and accordingly, they indicate the approximate course of the equilibrium curve. DTR (5a)

Application of the Binary and Ternary Diagrams in the Study of the Influence of Sulphur on Steels and Cast-Irons. (Applications des Diagrammes Binaires et Ternaires à l'Etude de l'Influence du Soufre sur les Aciers et les Fontes.) JEAN R. MARECHAL. *Revue Universelle des Mines,* Series 8, Vol. 7, Apr. 15, 1932, pages 389-397; May 1, 1932, pages 417-423.

The following systems were investigated and earlier literature on this subject reviewed: Fe-S, Mn-S, Fe-Mn-S, Fe-S-C, FeS-FeO, Fe-FeS-Fe_3O_4, MnS-Mn-O and FeS-FeO-MnS-MnO. S is always present in the form FeS; its solubility at low temperatures is insignificant both in Fe and in Fe_3C. FeS is found in most cases in the eutectic which is formed at the ternary eutectic point. With low C content, S exists in a binary eutectic and consists mainly of FeS. The solubility of S in austenite at low temperature is so weak that with decreasing temperature FeS is precipitated when the percentage of S exceeds 0.015%. With high C content, S is present as ternary eutectic. The eutectic Fe_3O_4-FeS is found in the diagram near FeS and contains only 0.25-0.5% FeO. The solubility of Fe_3O_4 in S is very weak even at temperatures of 1400°-1500° C. which is very likely the reason that in industrial analyses of samples magnetite has seldom been found. At very high temperatures, FeS and Fe_3O_4 form 2 liquid phases with a fairly weak solubility of Fe_3O_4 in the S and also in FeS in Fe_3O_4. The influence of admixtures of Si, P, Al, Ni, Cu, Zr, Ce and Ti on the other systems is briefly reviewed from literature and diagrams and micrographs reproduced. 32 references. Ha (5a)

THE LEITZ WORKS now offer for Micro-Metallograph "MM-1" and "MM-2" a novel darkfield illumination device and a series of objectives, contributing very materially to the efficiency of microscopical diagnosis of metal structures. These new products make possible a much more positive revelation and study of characteristic details which until now could not be observed.

THE POSITIVENESS with which the structure is revealed under Darkfield makes it extremely useful in research work for studying new alloys as well as in rechecking observations made in Brightfield. One of the most striking features of Darkfield observation and photomicrography is the extreme contrast coupled with maximum detail. It is practically impossible to obtain a Darkfield photomicrograph of mediocre contrast and the oblique illumination from all sides reveals to the best advantage all the intimate details of the surface being examined and this in a manner impossible to effect with the same degree of control by means of Brightfield illumination.

Equilibrium data are given for the Fe-Fe_4N system at 400° and 575° C. MEH (5a)

The Silver-Gold Alloys as a Type of Continuous Solid Solution (Les Alliages or-argent comme type de solutions solides continues). W. Broniewski & K. Wesolowski. *Comptes Rendus,* Vol. 194, June 6, 1932, pages 2047-2049.

The authors have studied 15 parameters of the alloys of this system as a function of their composition. The alloys were melted in vacuo in a high-frequency furnace. In order to obtain sufficient homogeneity in the samples the ingots were submitted to annealing at 800° C. for 50 hours. They were then drawn into wire 5 mm. in diameter, these wires being annealed finally for 1 hr. at 550° C. for the purpose of removing all the effects of cold work. Measurements of the 15 parameters were made and the results reproduced in a series of diagrams. The authors point out that the diagrams can be divided into 2 groups of curves: (1) those in which the curves rise and fall uniformly (without maximum or minimum) and (2) those in which the curves show a flat maximum or minimum. In the first group can be classed the melting point, e.m.f. of solution, the coefficient of dilatation, and the temperature coefficient of dilatation. All the other curves—electrical conductivity, temperature coefficient of electrical conductivity, thermo-electric power and its temperature coefficient, percentage elongation, hardness, tensile strength, elastic limit—belong in the other group. The characteristics of the curves in the second category are typical, then, of solid solutions; those of the others, with the exception of the fusibility curve, do not allow of solid solutions being distinguished from mixtures. OWE (5a)

The $\gamma-\eta-$Martensite as Widmannstätten Structure. (Der $\gamma-\eta-$Martensit als Widmannstättensches Gefüge.) Heinrich Hanemann. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 625-626.

Report of Metallographic Institute der Technischen Hochschule, Berlin. By a study of two γ- η- martensite polished sections, in planes running perpendicular to each other in the same crystal, it was established that the η- needles lie on correlated octahedral and cubic surfaces or planes. For this reason it is possible to designate the η- γ- martensite crystal structure as a representative "Widmannstätten" structure according to N. T. Belaiew's metal crystallization outline. The 7 directions to be expected were all to be found in the identical crystal section. The deviations from the ideal directions or bearings are less than in the case of the Widmannstätten structure of ferrite, the cubic plane spurs being more abundant. DTR (5a)

Metallographic Examination of Electric Arc Welds. (Metallographische Untersuchung von Lichtbogenschweissungen.) H. Hanemann & A. Hilpert. *Elektroschweissung,* Vol. 3, June 1932, pages 101-108.

The results of metallographic examinations of V- and X-welds made on 6 steel plates (C: .06-.50%) with 3 types of non-coated electrodes are reported. The microscopic examination particularly studied the effect of heat on grain size, formation of pores and structural uniformity of the joint. Mechanical tests were also performed. In the average the joint of all of the samples shows the same tensile strength as the base plate. The notch toughness, however, of all samples is considerably decreased and amounts to not more than 10% of that of the non-welded plate. GN (5a)

Metallography and Macrography. (Précis de metallographie microscopique et de macrographie.) Leon Guillet & Albert Portevin. Dunod, Paris, 1932. Paper 6½ x 10 inches. Price 128 Fr.

This is a standard text book of high value, which first appeared in 1914 and was translated into English by Tavener in 1921. Of course the fundamental principles and facts needed by students do not change much, so that it is perhaps not necessary that the book be revised much to serve its purpose. Yet it is certainly not as good a book as the authors could write today in the light of the metallurgical advances of the last 18 years. It is a misnomer to call this a third "edition," for it is primarily a reprinting with very minor changes and the addition of a few appendices which are largely rehashes of papers published elsewhere by Portevin. Even in the appendix, a paper published in 1920 is referred to as very recent. Aside from some generalities on corrosion, the main thing added in the appendix is a few equilibrium diagrams showing gamma loops. There is no alphabetical index. The paper used is not adequate to show up the micrographs well.

It is disappointing that these able authors did not really revise the book, retaining its valuable features, but incorporating recent advances in metallurgical knowledge in their logical positions in the book. There is no incentive for English-speaking readers to get the "new" edition if they already possess Tavener's translation.

H. W. Gillett (5a)-B-

Examination of the System Copper-Beryllium. (Untersuchung über das System Kupfer-Beryllium.) Heinz Borchers. *Metallwirtschaft,* Vol. 11, June 3, 1932, pages 317-321; June 10, 1932, pages 329-330.

The work of other investigators, given in 8 references, is discussed and irregularities are pointed out. It was found that Cu-Be alloys slightly attacked SiO_2 and C crucibles, so the tests were made in pure MgO crucibles, sometimes with a protective layer of BeO in an atmosphere of H_2. The constitutional diagram of Cu-Be was investigated up to 33% by weight of Be by thermal analysis, microscopic examination, dilatometry and electrical resistance measurements. CEM (5a)

Structure & X-Ray Analysis (5b)

X-Ray Crystal Analysis in Industrial Problems. *Engineering,* Vol. 133, Jan. 8, 1932, pages 29-30.

Brief summary of a report of a committee of the Department of Scientific and Industrial Research entitled "The Application of X-Ray Crystal Analysis to Industrial Problems." Examples are given of the type of work being done and the results obtained. X-ray photographs are reproduced. LFM (5b)

X-Rays for the Detection of Faulty Welds. *Welder,* Vol. 3, June 1932, pages 26-29.

Brief description of an X-ray apparatus and its application in the Babcock & Wilcox Works. Ha (5b)

X-Ray Diffraction Patterns. *Welding Engineer,* Vol. 17, Apr. 1932, pages 35-37.

A number of photographs explain the 3 principal types of diffraction patterns of metallic structures: (1) Patterns showing preferred orientation, indicating directional properties which will persist until the metal is heated sufficiently to normalize it. (2) Patterns showing a strained condition due to the banding of the crystals. Such a condition is characteristic of cast metal and can be considered as due to the amount of heat used, which naturally would be affected by the various rates of cooling. (3) Patterns showing random orientation of the crystals, indicating a state of equilibrium and consequently a more plastic or ductile material. Patterns produced in investigations of welds and welded structures usually belong to the second and third class showing strained conditions and the equilibrium condition. Welds which have been worked show preferred orientation because of the directional properties imparted by the working. The method of taking these patterns is described. Ha (5b)

Poly-Antimonides, Poly-Bismuthides and Their Transition into Alloys. III Communication on Metals and Alloys. (Polyantimonide, Polywismutide und ihr Übergang in Legierungen. 3 Mitteilung Über Metalle und Legierungen.) E. Zintl & W. Dullenkopf. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 16, Mar. 1932, pages 183-194.

Reports on a new set of experiments in Zintl's program of determining, when the complex structure of solid Na-compounds is going to change into the alloy structure with atomic space lattices, by alloying Na with S, Se, Te, As, Sb, Bi, Sn and Pb. The chemical preparations of the various compounds are given and special attention is called to the alloy Na-Bi. The powder photograms disclose a regular body-centered arrangement of atoms, of which 2 go into the unit cell. The density is $\delta = 6.63$. The various possible arrangements of the Na and Bi atoms are listed. No clues are furnished by powder photograms with reference to Na-Sb. Experiments with the Weissenberg-Bohm Röntgen-goniometer showed that Na-Sb crystallizes in the monoclinic system and that there are 8 atoms of Na and Sb to the unit cell. Higher poly-antimonides and poly-bismuthides decompose to Na-Sb and Sb and Na-Bi and Bi respectively. The X-ray investigations confirm the thermo-analytically determined constitutional diagrams Na-Sb and Na-Bi between 0 and 50 atomic % Na. EF (5b)

X-Ray Study of the System Gold-Platinum (Röntenuntersuchen im System Gold Platin.) W. Stenzel & J. Weerts. Festschrift zum Fünfzigjährigen Bestehen der Platinschmelze (1881-1931). G. Siebert, G. m. b. H. Publisher, G. M. Alberti's Hofbuchhandlung, Hanau. Pages 300-308.

Previous researches on this and related systems are briefly reviewed. The Au-Pt alloys were made from chemically pure metals by melting in magnesia crucibles in a Tamman furnace and then rolling. It was necessary to anneal certain alloys at a high temperature to complete the rolling. Specimens containing 50 to 60% Pt could be rolled cold after annealing several hours at 800°C. A specimen containing 75% Pt was brittle after this treatment; even after remelting, solidifying in the crucible, annealing 1 hr. at 1200°C., and quenching the alloy could not be rolled. In the study of the lattice constant of homogeneous alloys specimens .4 mm. thick and 2 cm. square containing approximately 10, 25, 40, 50, 65 and 90% Pt were quenched after annealing 1 hr. at 1020, 1020, 1160, 1190, 1275, and 1100°C. respectively. Cu radiations were used, and values were corrected to 20°C. by using theoretical coefficients of thermal expansion. The lattice constant for Pt was redetermined using specimens which had been treated in 5 different ways: (1) annealed 1 hr. in high vacuum at 930°C.; (2) same at 1200°C.; (3) heated 1 hr. at 1020°C. in air and quenched in water; (4) annealed 1 hr. in argon; (5) annealed 1 hr. in high vacuum, cooled, and then annealed 1 hr. at 1000°C. in argon. The average value found was 3.915 A.U., and there was little variation due to the different treatments. Using the value 4.070 for gold it was found that the lattice constant for the homogeneous alloys varied practically as a linear function of the atomic % concentration, the maximum deviation found being .002 A.U. As a means of studying the extent of the mutual solubility of these metals at lower temperatures, alloys containing 40, 50, and 60% Pt were heated to temperatures of 1108, 1065, 985, 875, and 675°C. for 1, 1½, 4½, 40, and 170 hrs. respectively, quenched in water, and the crystal lattices of the resulting structures determined. From the previously determined lattice parameter for Au-Pt alloys, the Au and Pt contents of the Au-rich and Pt-rich phases in the duplex structures were calculated, a change of .001 A.U. in parameter corresponding to a change of about .65 atomic %. The maximum temperature of the field of limited solubility was found at about 1180°C. and at about 60% of Pt. At 1100, 900, and 700°C. the solubility of Pt in Au was found to be 43, 30, and 25 atomic % respectively, while the corresponding solubilities for Au in Pt were 19, 7, and 3½ atomic %. The results found by this method of investigation agreed well with those previously reported by Johansson and Linde. The solubilities below 675°C. were not investigated. OEH (5b)

IF FLAWS ARE CONCEALED THE X-RAY WILL REVEAL THEM

THE manner in which the x-ray is utilized varies in different industries. Most boiler manufacturers radiograph all welded seams as routine procedure. An aluminum foundry reports that it is employed "both in determining the foundry technique which will give the most satisfactory casting and as a production check in order to maintain the original standards." Wire drawing and rolling mills use it to analyze, by means of diffraction patterns, the effect of various treatments on materials.

Nine years ago the General Electric X-Ray Corporation established a special department for the study of the industrial application of the x-ray and to develop apparatus and methods which would adequately meet the increasing requirements for the examination of fabricated materials. This Industrial X-Ray Department is continually devising and installing specialized apparatus for the examination of welds, castings, rolled and drawn metals, hidden assemblies—in fact, for every industrial product in which invisible defects present a problem.

Are you interested in this use of the X-Ray? If so, we will be pleased to send you the latest literature on the subject.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Modern Theoretical Foundations of Materials-Testing of Metals. (Die heutige theoretische Grundlage der Materialprüfung der Metalle.) W. ENGEL. *Danmarks Naturvidenskabelige Samfund*, Copenhagen, 1931. Paper, 6¾ x 9¾ inches, 67 pages. Price 3 Kr. In German.

1 A brief discussion of crystal structure and slip in single crystals and polycrystalline material in their bearing on testing; of the influence of test bar shape, speed of testing, etc. Creep fatigue, "Trennfestigkeit," etc. are mentioned as well as tensile and impact tests. The problem of yield strength is quite fully discussed. A useful feature is an explanation of what the German and the Danish terms relating to mechanical testing really refer to. H. W. Gillett (6) -B-

Portable Weld-Testing Machine. A. EYLES. *Mechanical World & Engineering Record*, Vol. 89, Mar. 27, 1931, page 295.

2 The new Southwark-built Oxweld portable testing machine is an accurate, reliable, inexpensive machine for routine testing or for small laboratories and welding shops, where the investment in a large universal machine would be unwarranted. The machine, which is illustrated and described, weighs 165 lb., measuring 28" in overall length and 6¾" in diameter. The load is applied by means of a small hand pump, operating a piston, carrying one set of grips, the other set being held in a holder rigidly attached to the machine. The stress is measured directly in lb./in.² (standard size specimens by suitable calibrated pressure gage. WHB (6)

Magnetizability of Mixed Substances. (Ueber die Magnetisierbarkeit von Mischkörpern.) E. GEROLD. *Archiv für Elektrotechnik*, Vol. 26, Mar. 22, 1932, pages 168-176.

3 A revised measurement of alloyed substances in which a ferromagnetic material is embedded in very fine distribution in a non-magnetic material led to the conclusion that the magnetized particles do not act on one another as long as the ratio of the average distance of their centers to their average diameter is larger than about 1.6 to 2. For mixed substances where this ratio < 1.6 the specific magnetization per g. of the ferro-magnetic constituent increases with the decrease of the ratio if the shape of the sample and the shape

4 of the ferro-magnetic constituent are different; if both have the same shape this effcet disappears and for the saturated state the shape has no influence on the magnetization for all ratios of mixture. The magnetization curves permit conclusions with regard to the ratio of length to diameter of the ferro-magnetic particles. Ha (6)

The Hardness of a Steel Tube Along Certain "Lüders" or "Piobert" Lines. HENRY FOWLER. *Engineering*, Vol. 132, Sept. 4, 1931, page 299.

Contribution to the Report of the Committee on Stresses in Overstrained Materials presented to Section G of the British

5 Association for Advancement of Science, Sept. 1931. LFM (6)

Indentation Hardness of Test Pieces Resulting from Plastic Flow. HENRY FOWLER. *Engineering*, Vol. 132, Sept. 25, 1931, pages 420-421.

Contribution to the Report of the Committee on Stresses in Overstrained Material presented to Section G of the British Association for Advancement of Science, Sept. 1931. LFM (6)

Portable Hardness Testing Instruments

THE DUROSKOP

4⅛" x 4⅛" x 1¼"
Weight 13 ozs.

Falling pendulum principle with pointer held at highest point of rebound.

Can be used on vertical, inclined or horizontal surfaces, wherever the piece may be. Very rapid for exploring large pieces for soft spots. Very valuable for determining dynamic quality of metals. Useful for other materials—ceramics, rubber, fibre board, plastics, wood, stone. Modified form for testing wires. Also Laboratory Duroskop provides variable height of fall of pendulum.

Ask for Bulletin H-4 describing this and a Dwarf Brinell Press.

THE R. Y. FERNER CO.
1133 Investment Bldg. Washington, D. C.

INDUSTRIAL USES & APPLICATIONS (9)

Investigating Machinery Performance and Design. Louis Jordan. *Commercial Standards Monthly*, Vol. 8, Apr. 1932, page 301.

The design and performance of machinery reflects promptly and in great detail current advances in knowledge of the fabrication and treatment of metals. All research in physical metallurgy is, either immediately or ultimately, of interest to the builders and users of all types of machines. Among the active research projects of the Division of Metallurgy at the Bureau of Standards several of the problems are of rather immediate interest in this survey of machinery. The various metallurgical research problems under consideration are briefly enumerated. Among these are investigations on the wear and machinability of metals; the properties of metals at high and low temperatures; the changes in volume of metals during casting; the fluidity of metals during casting; methods of controlling the conditions of foundry sands; the corrosion of metals; the failure of metals by fatigue, popularly but erroneously described as failure by crystallization. WAT (9)

The Rail Question. (Zur Schienenfrage.) A. Hasch. *Stahlbautechnik*, Supplement to *Montanistische Rundschau*, Vol. 24, Mar. 16, 1932, pages 5-7.

The article deals with the testing of rails by the Vienna Street Railway System. The successful practical application of rails depends on the elimination of failures due to frosty weather, a high resistance to wear and good weldability. GN (9)

The Value of Chromium Plated Screws in the Chemical Industry. (Über den Wert verchromter Schrauben in der chemischen Industry.) Carl Hütter. *Die Chemische Fabrik*, Feb. 24, 1932, pages 59-60.

The use of Cr plated screws and nuts in HNO_3 manufacturing plants has prolonged the life of the screws, reduced repair costs and eliminated shutdowns. Cr is plated direct on steel at low current density, without preliminary Ni plating. Cr deposited in this way is comparatively soft but free from porosity. The screws are tested by boiling in HNO_3 for 2 to 3 weeks and should show no loss in weight during this test. CEM (9)

The Application of Nitrided Steel Parts in General Engineering. J. E. Hunt. *Iron & Steel Industry & British Foundryman*, Vol. 5, Mar. 1932, pages 235-239.

A brief discussion of the nitriding process. The application of nitrided steels for valve parts, cams and gears, machine tool and textile machinery parts, and wear and fatigue resistant parts are described. CHL (9)

Metallic Construction of Airplanes (La Construction Métallique des Avions). G. R. Hamel. *Aciers Spéciaux, Métaux et Alliages*, Vol. 7, Mar. 1932, pages 93-98.

Mechanical features of airplane construction are generally discussed. GTM (9)

An Electrically Welded Airplane Hanger in Brazil (Eine elektrisch geschweisste Flugzeughalle in Brasilien.) H. Hinden. *Elektroschweissung*, Vol. 3, Apr. 1932, page 79.

Short description of an airplane hangar recently built at Rio de Janeiro, Brazil. The hangar has a span width of 34 m. and is completely welded. GN (9)

Service Pipe Practices. H. A. Harris. *Water Works Engineering*, Vol. 85, Apr. 20, 1932, pages 430-432.

Standardized methods employed by a large water company in making service installations with Cu and cast iron pipe. Studies were based upon a great many soil and water conditions. CBJ (9)

Some Notes on Steel Shipbuilding. N. M. Hunter. *Advance Paper, Institution Engineers & Shipbuilders*, Newcastle-on-Tyne, Mar. 1932, 15 pages.

Although the various parts of a ship's structure and also the methods of fabricating and putting them together have been standardized to a great extent there remain still some special jobs where this is not possible and which the author discusses and illustrates by a great number of drawings. Electric welding is applied very extensively as it combines strength with lightness, eliminates all danger of leakage and the necessity of caulking. This latter especially is a source of weakening the riveted structure. Ha (9)

Metallurgy and the Motor Car Industry. Robert Hadfield. *Heat Treating & Forging*, Vol. 18, Jan. 1932, pages 24-27; Feb. 1932, pages 102-103.

Progress in the automobile industry has been made possible largely by the discoveries and products of the metallurgist, particularly in the field of alloy steels. Performance of the modern car is due to the fact that the working parts which are subject to severe stresses and vibration are made from modern special steels. Their use is more economical than ordinary steel, notwithstanding their higher cost per lb., as a great reduction in weight is obtained, as well as improved physical properties. Knowledge gained from the development and use of these materials has favorably influenced the manufacture and treatment of C steels. Heat-resisting and stainless steels are finding important applications. The former are used in the valves of internal-combustion engines and the rotors of exhaust-gas turbines and improve engine efficiency. Author's firm in collaboration with several others, has developed a Ni-Cr steel having a tensile strength of 21.5 tons/in.^{2} at 800° C. Si-Mn steel is superior for springs. The rolled eye is to be favored for the master leaf of springs. A combination of various methods of testing is necessary to arrive at an idea of the quality of a material. Best results can be obtained only by paying the most careful attention to all stages in the manufacture of steel. Gives results of some comparative tests on Ni-Cr steels containing different total amounts of S and P. For example, a Ni-Cr steel with 0.64% C and 0.08% S+P, and having a Brinell hardness of 600, withstood 60,000 blows in a repeated impact testing-machine. A similar specimen containing only 0.027% S+P with the same hardness, withstood 167,000 blows before fracture. In the Stanton repeated impact testing-machine, the first steel withstood 52 blows, while the second withstood over 160 blows. One outstanding lesson of recent metallurgical progress is the importance of continual research. MS (9)

Research and Practice with Widia Metal Used in Chisels for Cutting Coal. (Versuche und Erfahrungen mit Widia-Schrammeisseln.) J. Menke. *Glückauf*, Vol. 68, Apr. 9, 1932, pages 337-343.

1 Widia metal is prepared by mixing pure W and pure C in weight proportion to form tungsten carbide, WC. The mixture is kept at a definite temperature for a time, until WC has formed. The WC is pulverized, 4 to 6% Co is added, and carefully mixed together. The desired shapes are pressed out under extremely high pressures, sintered in an electric furnace at 1400 to 1600° C., with air excluded. The Co fuses and acts as a binder for WC. The product is Widia metal and is ready for use as tool metal in coal cutting machines. Production of Widia metal coal-cutting chisels and bar picks is described. Shaft of the tool is Cr-Ni-Mo Steel with T. S. minimum 150 kg./mm.^{2} Cutting or working end is Widia metal. The latter is brazed to the shaft 2 at 850° C., a thin bronze sheet or strip is placed in between shaft and cutting end, to take care of variations in expansion. Comparisons were made of cost, life, amount of sharpening work for W-Steel, Stellite and Widia metal. After extensive series of practical tests, running over number of months, it was demonstrated that Widia cutting tools give: (1) simplified cutting work with decreased costs; (2) with very hard coal, especially when pyrites and clay bands are present, considerable savings in compressed air and labor is possible; (3) since Widia chisels never become as dull as steel chisels, and since the coal cutting machine 3 is driven carefully, less trouble occurs to the machine, with resulting increased life and decreased use of spare parts; (4) less amount of small coal sizes are produced due to narrower cut. DTR (9)

Metal Baths for Heating, Distilling and Similar Apparatus. (Metallbäder für Koch-Destiller und Ähnliche Apparate.) M. Grellert. *Apparatebau*, Vol. 43, Oct. 2, 1931, pages 229-230.

The article refers to a former publication (T. Melz, Metallbad zur Wärmeübertragung für Koch-, Destillier und ähnliche Apparate, *Apparatebau*, Vol. 43, Apr. 2, 1931, pages 76-77) in which a new heating method has been described. The 4 author states from his own experience that the new method is disadvantageous and doomed to failure. GN (9)

Material for Diesel Cylinder Liners. M. E. Greenhow. *Power*, Vol. 75, Apr. 12, 1932, pages 546-547.

A general review is given of cast Fe composition and properties. AHE (9)

Oxy-Acetylene Welding Applied to Scales. F. C. Hasse. *Scale Journal*, Vol. 18, May 1932, pages 5-6.

The properties of O and C_2H_2 are briefly described and the apparatus and methods for welding explained. The advantages of welding the rails on scales are stated to be: 5 smooth running of cars over scale, impacts to joints are eliminated, angle bars and the necessity for tightening bolts that hold rails and become loose due to impacts at joints are eliminated. Ha (9)

Welding of A Bridge. (Ausführung einer geschweissten Fachwerksbrücke.) L. Gerstenberg. *Stahlbautechnik, Supplement* to *Montanistische Rundschau*, Vol. 24, Mar. 16, 1932, pages 1-2.

Description of the welding of a bridge in the harbor of Hamburg. GN (9)

Metal Pipe and Flexible Tubing in Auxiliary Ventilation of Metal Mines. Oscar A. Glaeser & S. H. Ash. *Mining Congress Journal*, Vol. 18, Apr. 1932, pages 24-26.

6 Auxiliary ventilation of dead ends of drifts in metal mines, and in boring of large and small tunnels, has become an important phase of driving operation. In tunnel driving standardized practice now exists, but in metal mines, little attention has been paid to efficient operation of auxiliary ventilating equipment. Some doubt has existed as to whether metal pipe or flexible tubing should be used and also relative economy. Zn-coated Fe, 22 to 14 gage, is most commonly used as metal tubing or pipe, depending upon size of pipe and mining conditions. 20-gage metal is considered too light 7 for 16" pipe. An example giving comparative cost of a typical installation is shown: Assume that during a 12-month period 15,000 ft. of duct is installed:

	16" flexible tubing		16" pipe	
Item	Total	Per ft., cts.	Total	Per ft., cts.
Labor	$ 711.00	4.74	$ 1,992.00	$ 13.28
Depreciation & Shrinkage, 20%	1,830.00	12.20	645.00	4.30
Material	9,150.00	61.00	12,900.00	86.00
	$11,691.00	77.94	$15,537,00	$103.58

10 **Construction of an Overcrossing on Steel Piles.** Milo S. Farwell. *Engineering News-Record*, Vol. 108, Mar. 31, 1932, pages 463-464.

A highway structure 1,380 ft. long was constructed in California. Welded connections were used for the first time on a major highway structure by that state. Complete details are included. CBJ (9)

Heat Insulation with Metal Foil. J. L. Gregg. *Product Engineering,* Vol. 3, May 1932, pages 204-206.

The rather paradox phenomenon of the use of metals as heat insulators can be brought about by 2 methods which are described in detail. In one way flat sheets of foil are held apart by suitable spacers between which the air acts as insulator as it is held stationary and, therefore, can not conduct heat by conduction. In the other way, foil sheets are slightly crumpled and stacked one on top of the other to form irregular air layers with the same effect as before. The foil used has a thickness of 0.00025". Foil covered paper is used to give the metal sufficient mechanical stiffness. The heat insulation compares very favorably with the more generally used heat insulating materials, for instance 0.34 B.t.u. as compared with 0.38 with corrugated paper or 0.32 for cork. Several methods of practical application are explained. Ha (9)

Experiences in Building Nickel Apparatus. (Erfahrungen im Bau von Nickelapparaten.) M. Grellert. *Apparatebau,* Vol. 43, Jan. 9, 1931, pages 1-5.

The article deals with the difficulties which were encountered in building chemical vessels of pure Ni which had to stand a pressure of 50 atmospheres and a temperature of 250° C. The difficulties were in particular caused by the customer's demand that a 98% Ni be used. GN (9)

The Application Possibilities of Aluminum in Modern Structures. (Ueber die Verwendungsfähigkeit des Aluminiums im neuzeitlichen Bauwesen.) W. Elsner von Gronow. *Aluminium,* Vol. 14, Feb. 29, 1932, pages 2-5.

The uses and advantages and economies possible are discussed quite generally with reference to buildings, in particular for roofing and window fixtures where Al and its alloys have found great use. Ha (9)

The Tungsten Lamp. W. E. Forsythe & E. M. Watson. *Journal Franklin Institute,* Vol. 213, June 1932, pages 623-637.

Use of W for incandescent lamp filaments is narrated. Outstanding properties that make W valuable for this special purpose are: (1) favorable radiating characteristics; (2) lower vapor pressure and high melting point; (3) high tensile strength; (4) its ductility. Sufficient supply of this metal exists so that filament costs are not excessive. Originally there was no ductile W wire, and in 1910 Dr. Coolidge discovered a method of making ductile W wire of almost any diameter. This was the most important step in lamp making. W was not chosen as the material for the present day lamp filament by any accident or guess, but it was chosen because it possessed outstanding and suitable metal properties for this purpose. Brief mention is made of Nernst flower, Ta, Os, filamentless lamps. Efficiency of W as a light source as a function of its temperature is given. At 2000° Kelvin, efficiency is roughly 3 lumens/watt and at 3600° Kelvin, 50 lumens/watt. This is a slightly higher efficiency than that of a black body with similar temperature variation. Other characteristics, lamp efficiencies and losses, frosted lamp bulb studies are discussed. DTR (9)

Alloys in Machine Tools. D. M. Gurney. *Heat Treating & Forging,* Vol. 18, Feb. 1932, pages 113-114; Mar. 1932, pages 185-186.

Paper presented before the Conference on Metals and Alloys, Case School of Applied Science, Cleveland. See *Metals & Alloys.* Vol. 3, July 1932, page MA 215. MS (9)

Beryllium and Its Alloys. (Beryllium und seine Legierungen.) H. Fischer & G. Masing. *Die Naturwissenschaften,* Vol. 19, July 3, 1931, pages 590-595.

Discovery, relative distribution on earth, natural occurrence, chemical preparation according to Wöhler, Stock, Goldschmidt, and commercial production methods (Siemens & Halske) are covered in the introduction. The utilization of Be in light metals and alloys proved to be commercially unimportant, whereas fargoing effects were noticed in heavy metals due to Be-additions. The age-hardening prerequisition in regard to the course of the solid solution line was met with in the following binary systems; Cu-Be, Ni-Be, Co-Be and Fe-Be at concentrations between 2-4% Be. The commercial significance of Cu-Be alloys is shown by comparing the strength data of these alloys with bronze. Great fatigue strength and elasticity predict the use of Be-bronze for springs. The Ni-Be alloys are under development, their remarkable strength being emphasized. The addition of Be to Fe with a low content of Ni is discussed. The use of Cu-Be alloys for deoxidizing purposes is urged and the superiority to P, Mg, Ca, Al is claimed. The advantageous utilization of Cu-Be alloys as bearing metals is considered. The paper concludes with the theoretical results of investigations into precipitation hardening in Be-alloys. EF (9)

Beryllium. K. G. Frank. *Scientific American,* Vol. 146, May 1932, pages 270-271.

Metallurgical research and investigation has succeeded in definitely putting Be on the list of metals for commercial use. The improvements obtained by additions of 1-1½% of Be to Cu alloys is briefly described. The commercial production of Be is outlined. The present cost of Be is about $80 per lb. a substantial reduction from $225 per lb. in 1930. WAT (9)

Architectural Metals. I. R. Disbro. *Case School of Applied Science Conference on Metals & Alloys,* Cleveland, Nov. 1931, 17 pages. Mimeographed.

Discussion of artistic architectural effects obtained with various alloys. Solid metals are preferred to plated ones, by the architect. Corrosion is important in choosing a metal for exterior use. Wrought Fe is characterized as prone to rust, needing oiling or waxing. Stainless steel requires care not to put other metals in contact that would set up electrolytic action. Monel is said to be free from this difficulty. Pb, Al bronze and Al are among the metals least affected by outdoor exposure. The green patina on Cu is pleasing, but the black tarnish on brass is not. The use of bronze dates from antiquity, and it is doubtful if any of the newer metals, despite temporary vogues, will ever be able to do more than compete with it where the best in architectural decoration and utility is required. For some exterior uses, bronze should either be lacquered yearly or waxed every month. The contrast between matt and shiny Al makes it especially useful in decoration. Stainless steel is assured of a continued demand. Modern tendencies are toward simplicity rather than ornateness. HWG (9)

Concrete Culverts Lengthened with Corrugated-Iron Pipe. H. A. Pabst. *Engineering News-Record,* Vol. 108, June 16, 1932, page 859.

When highway was widened to meet new standards existing concrete culverts were extended by special corrugated-iron pipe with expansion end. CBJ (9)

All-Welded Factory Extensions at Murex Welding Processes, Ltd. F. O'Connor. *Welder,* Vol. 3, May 1932, pages 7-21.

The design and construction details of a factory building covering 37,000 ft.² having a length of 231 ft. and a span of 160 ft. is described. Ha (9)

The All Metal Monoplane "Breda 32" (Il monoplano interamente metallico "Breda 32") A. Parano. *Alluminio,* Vol. 1, Jan.-Feb. 1932, pages 36-40.

The stress-carrying members and the fuselage and wing coverings of this tri-motored transport plane are duralumin. Motor cowling, window frames, chairs, and many secondary parts are of wrought or cast elektron. No metallurgical details are given. HWG (9)

Aluminum Alloy Conductors, Aldrey. (Conduttori in lega di alluminio, I conduttori in Aldrey). C. Pramaggiore. *Alluminio,* Vol. 1, Mar.-Apr. 1932, pages 80-107.

Electrical conductors of Aldrey, 0.60% Si, 0.45% Mg, 0.25% Fe, which have been given the precipitation hardening or accelerated aging heat-treatment are compared with steel cored, unalloyed Al cables and with Cu conductors. One Aldrey line has been up 7 years, and its corrosion-resistance is considered equal to that of commercial unalloyed Al. The hardness of Aldrey makes it less liable to damage during erection than Al. Its tensile strength is about 47,000-50,000, its yield strength (0.05% set) 42,500 and 38,500 (0.2% set), and its permanent load-carrying ability about 40,000 lbs./in.², with 6 to 7% elongation in 8", 90 to 100 Brinell. Its endurance limit, rotating beam, 20 million cycles, is 14,500 to 17,000 lbs./in.². Conductors of equivalent conductivity are Cu 94, pure Al 153, steel cored Al (30 Al, 7 steel wires) 178, Aldrey 171, mm.². These, carrying the same current, will give the following temperature rise in deg. C., Cu 40°, Al or Al-steel 36°, Aldrey 32°. Proper mounting of conductor cables will avoid failure from repeated stresses. Various methods of mounting on rigid insulators and of anti-vibration mountings of oscillating suspensions, of connecting Cu and Aldrey cables with insulating washers to avoid contact corrosion, and methods of jointing, as by right and left handed turn trickle connections, by twisted sleeves and by sleeves forced on by wire drawing, swaging or compression methods, are illustrated by photographs. The corona effect and loss of energy in transmission, etc. on lines of different materials discussed. Author with firm producing Aldrey. HWG (9)

Steel Plates with Welded Joints Seal Rockfill Dam. H. I. Reid. *Engineering News-Record,* Vol. 108, May 26, 1932, pages 761-763.

An unusual application of welding was made in constructing the steel-plate facing for a rockfill dam for the new water supply for the Broadmoor Hotel, which is about 5 miles from Colorado Springs, Colo. Structural-steel plates 20 ft. long and 8½ ft. wide containing not less than 0.2% Cu were used. All joints and all assembling bolt heads were welded to insure watertightness. CBJ (9)

A New High-Pressure Cast Joint for Gas and Water Transmission Pipes. (Eine neue Hochdruck-Gussrohrverbindung für Gas- und Wasserleitungen.) C. Pardun. *Das Gas- und Wasserfach,* Vol. 75, Jan. 30, 1932, pages 89-91.

Necessity has led to a demand for joints which cannot be damaged and hence cause economic loss and trouble. High-pressure joints in the past have been made of Pb covered with hemp. Today the effects of corrosion and higher pressures require something better. Solders or welds have not proved satisfactory in the United States. The cast Fe in pipes lacks sufficient elasticity, and this causes fractures. Steel tube joints have to be supplied with a muffle or similar equipment with packing gland. Hence to supply both density and strength in length and cross-section, a cast piece is placed over joint. Rubber is used as a packing agent. MAB (9)

Nickel and Nickel Alloys in Marine Engineering. J. McNeil. *Metal Industry,* London, Vol. 39, Dec. 18, 1931, pages 583-585; Dec. 25, 1931, page 609; *Iron & Coal Trades Review,* Vol. 124, Feb. 12, 1932, page 277.

From a paper read before the Institute of Marine Engineers, Dec. 1931. Thick deposits of Ni of BHN 320-350 are used for repair work and for corrosion prevention of expansion sleeves subject to the action of superheated steam. Ni plated cast Fe propellors are being tried out in service tests. Ni-Cu 70:30 alloys find use because of high limiting creep values at high temperatures. Cu-Ni 70:30 alloys are used in water tube boilers. Monel metal finds use for propellor shafts, turbine blading, valve parts in steam lines, etc. Ni bronze is a successful development for propellors of fast multiple-screw ships. Alloys of 65 Ni, 15 Cr and Fe, with special additions to increase sulphur corrosion resistance at high temperatures are used for superheater tube supports, baffle plates of furnace doors, furnace arch supports, etc. Ni in cast Fe is being experimented with. PRK+Ha (9)

Future Fields for Alloy Steels. J. M. Schlendorf. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 31-32.

Alloy steels will find extensive application where strength is important and in the making of stampings. Trend toward the use of alloying elements in small amounts is increasing, particularly for purposes of uniformity, and it is to be expected that much wider use of Si, Cu, Mn, Cr and similar elements will be made in the future. Perhaps the greatest future development of alloy steels lies in their ability to resist atmospheric corrosion. These steels will be of a simpler nature with lower alloy content than the present highly alloyed stainless steels. An equally great field for alloy steels lies in their use as heat-resisting materials. Not only do they resist scale formation, but they possess high strength at elevated temperatures. MS (9)

Hardening a Clock Balance Staff, Development of Present Practice. J. A. Reinhardt. *Metal Progress,* Vol. 21, May 1932, pages 55-60.

Gives the history of metallurgy in the clock factory. Modern heat treating and testing to specifications of balance staffs are described. Extensive tests indicate that plain C steel parts wear longer than Cr and Mo alloy steels. WLC (9)

HEAT TREATMENT (10)

Annealing (10b)

Effect of Gaseous Atmospheres in the Bright Annealing of Metal. R. J. Cowan (Surface Combustion Corp.). *Fuels & Furnaces,* Vol. 9, Nov. 1931, pages 1307-1308.

From a paper read before the American Gas Association and published in *Steel,* Vol. 89, Aug. 13, 1931, pages 34, 36, 38. See *Metals & Alloys,* Vol. 3, May 1932, page MA 131. MS (10b)

Bright Annealing of Metals with Hydrocarbon Gases. E. G. de Coriolis & R. J. Cowan. *Industrial & Engineering Chemistry,* Vol. 24, Jan. 1932, pages 18-20.

See "Use of Hydrocarbon Gases for Bright Annealing of Metals," *Metals & Alloys,* Vol. 3, May 1932, page MA 131. MEH (10b)

The Annealing of Steel Castings. W. R. D. Jones & P. Field Foster. *Proceedings South Wales Institute of Engineers,* Vol. 48, Apr. 7, 1932, pages 43-66.

Annealing medium C steel castings at 875° C. for 1 hr./inch of cross-section is satisfactory. Prolonged exposure to the annealing temperature is not an advantage but no serious damage is done to the static properties. Tensile tests are not affected seriously by inclusions present, but they have a very pronounced effect on resistance to fatigue. Annealing at 875° C. lowers the fatigue-resisting properties, and the longer the annealing the lower is the fatigue limit. This is due probably to the accentuating of the bad effect of inclusions by prolonged exposure to the high temperatures of annealing. Annealing at 760° C. gave more regular results in the fatigue experiments. AHE (10b)

Electric Furnaces for Bright-Annealing Process. H. C. Kloninger, G. Keller & H. Meuche. *Engineering,* Vol. 132, Sept. 18, 1931, pages 390-393.

Condensed from paper entitled "Applications of the Electric Furnace for Non-Ferrous Metals, with Special Reference to the Bright Annealing Process" read before the Institute of Metals, Zurich, Sept. 14, 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 308. LFM (10b)

Case Hardening & Nitrogen Hardening (10c)

Studies on the Formation of Different Carbides with Methane. (Untersuchungen über die Bildung verschiedener Metallkarbide mit Methan.) Rud. Schenck, Fr. Kurzen & H. Wesselcock. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 203, Dec. 30, 1931, pages 159-187; abstract, *Stahl und Eisen,* Vol. 52, June 2, 1932, page 545.

The nature of the action of C on metals at high temperatures was studied. Equilibrium between different C-phases and Fe was found at 0.47, 0.74 and 0.99% C. Action of CH_4 on Cr results in Cr_5C_2 and solid solutions between 600 and 800° C., and Cr_3C_4 and Cr_3C_2 are found under certain conditions. The carbonization of W produces the unstable W_5C_2 and an unstable solid solution phase, which contains in addition to W_5C_2 still another unstable higher carbide, apparently W_3C_2. At 800° C. the stable WC only is formed. Above 800° C. the rate of transformation of the unstable carbide is very high and only a single carbide, the stable WC is formed One stable carbide Mo_2C resulted from action of Mo with CH_4. At 700° C. a metastable phase seems to exist. In the case of Re only a few tenths % of C is taken up by the metal, the reaction with CH_4 being very slow. 12 references. Ha+DTR (10c)

Nitrogenization of Steel by Ammonia and Aging Phenomena. (Azotowanie stali przez amoniak i zjawiska starzenia.) I. Feszczenko-Czopiwski & Wojcik. *Prace Badawcze PWU,* 1931, No. 1, pages 51-122.

48 references. Based on the results obtained it is suggested that the solubility of N in Fe is greater than that indicated by Fry in his Fe-N diagram. The only steels practically suitable to nitrogenization are the Al and Cr steels; although hard C steels containing an admissibly great amount of Si and Mn can be nitrided in some cases. The following conditions were found to be the best for nitriding of Al and Cr steels: 540° C. as the temperature of process, during 30 hours and at 20% of dissociation of ammonia. The next table gives the results of aging of some nitrided steels.

Analysis C%	Cr%	Al%	Hardness in Brinell units after nitriding and hardening	aged during 40 days
0.34	1.6	1.04	800	890
0.36	15.6	...	750	820

ZJ (10c)

Some Experiments on the Nitrogen-Hardening of Cast Iron. J. E. Hurst. *Iron & Steel Institute, Advance Copy* No. 9, May 1932, 10 pages.

The properties of nitrided Al-Cr cast iron were determined. An iron suitable for nitriding used for cylinder linings is marketed under the trade name of "Nitricastiron." Centrifugally cast and sand cast specimens were used. The former had the greater hardness. The iron was heat treated before nitriding. The nitrided iron had a hardness of 982 and a penetration of 0.018 in. The hardened layer on the centrifugally cast specimen was greater than that on the sand cast specimen, but not as great as the case on Nitralloy. The iron contained 2.6% total C, 2.5% Si, 0.6% Mn, 1.6% Cr and 1.4% Al. The centrifugally cast material contained 1.55% combined C and the sand cast 0.85%. JLG (10c)

What is Carburizing? (Ou en est la cémentation au carbone?) Bernard Jousset. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Jan. 1932, pages 2-11.

An exposition of advantages and disadvantages of the many existing processes of cementation of steels. GTM (10c)

1 **The Theory and Practice of Nitrogen Case-Hardening.** A. Fry. *Iron & Steel Institute, Advance Copy* No. 8, May 1932, 22 pages.

Bibliography of 26 references. Reviews his development of the nitriding process, and discusses some of the recent work on the Fe-N system. The stability of the various nitrides was determined by heating in vacuo. The nitrides of Fe and Mn decompose at comparatively low temperatures. Cr nitride decomposes at about 900° C. Al and Ti nitrides are stable up to at least 1100° C. The extreme hardness of the nitrided layers in special steels is attributed to slip interference produced by nitride particles formed on treatment with NH_3.

2 The case is shallow because of the great stability of the Al and Cr nitrides formed as an extraneous phase in the Fe lattice. If nitriding is carried out at too high a temperature the nitride particles produced are too large to produce a case with the best properties. The nitride particles prevent diffusion of the NH_3 into the steel, and the case is therefore thin. The effects of nitriding on the fatigue limit and corrosion resistance are mentioned. JLG (10c)

Case Hardening with Nitrogen. J. E. Magoffin. *Sibley Journal of Engineering,* Vol. 46, Apr. 1932, pages 89-90.

The nature of nitrogen or case hardening is explained and the usual methods are briefly described. A great advantage of nitrogen hardening is that because of low temperature and short time of exposure, no heat treatment of the steel is necessary. Grain growth is avoided and the piece has become stronger by a less expensive process; it equals purely carbon hardened steels. 5 references. Ha (10c)

5 **Rugged and Dependable Nitriding Steel.** *Heat Treating & Forging,* Vol. 18, Feb. 1932, page 112.

Union Carbide & Carbon Research Labs., Inc., has developed a nitriding steel containing 0.50-2.50% Cr, 0.30-2.50% V and up to 0.70% C, depending upon physical properties desired. It has many of the physical properties of the S.A.E. 6100 series. About 0.30% V in excess of that required to form VC is necessary, as the presence of this amount of V in the unbound form is important in securing surface hardening with N. Best results are obtained by NH_3 nitriding, particularly where a comparatively heavy case is required. A case as thick as 0.04" can be obtained by this method.

Purest Steels Develop Soft Spots if Carburized and Quenched. F. Duftschmid & Edouard Houdremont. *Metal Progress,* Vol. 21, May 1932, pages 30-33, 92.

The authors have produced very pure Fe-C alloys from Fe produced by the decomposition of the carbonyl and pure gas carbon. Such steels show in hypo- and hypereutectoid composition the "abnormal" tendency to agglomerate the cementite. The grain size of such very pure alloys is not small as in commercial abnormal steels which the authors explain by the entire absence of any centers of crystallization in the form of alumina or other non-metallics present in commercial steels. Thermal study shows the hysteresis at A_1 point to be very small. Ac_1 1314° F. and Ar_1 1292° F. The addition of transformation retarding elements to these pure alloys, such as Mn and Cr, have entirely removed the tendency to agglomerate the cementite. The presence of "abnormal" features in badly segregated areas of high S and P is according to the authors due to presence of some regions

8 of very pure Fe. The rapid transformation of pure alloys results in agglomerations of the cementite but slow or retarded transformation due to Mn, Cr or other alloy allows time for the formation of plate pearlite and cementitic grain boundaries in hypereutectoid steels. WLC (10c)

The Loss of Carbon from Iron and Steel When Heated in Decarburizing Gases. A. Bramley & K. F. Allen. *Engineering,* Vol. 133, Jan. 22, 1932, pages 92-94; Jan. 29, 1932, pages 123-126; Feb. 19, 1932, pages 229-231; Mar. 11, 1932, pages 305-306.

Quantitative tests were made to determine the relationship between the extent of decarburization and the C gradient within the steel. Attempt was made to discover

9 whether the removal of C by decarburizing agents is governed by laws similar to those which apply to the introduction of C during the cementation process. Several series of tests were made. The C content of the steels used varied from 0.85 to 2.00%. Tests were made using dry and moist hydrogen and a mixture of CO and CO_2 as decarburizing agents. The results are shown graphically. One series of tests was made to determine the effect of temperature on the rate of decarburization, the temperatures used varying from 800° to 1100° C. An examination was made of the

10 microstructures of the steels treated, photomicrographs being given showing the structure. One section of the paper deals with the application of Fick's law of diffusion to the movement of C in steel. Decarburization tests at various temperatures made on a 2.0% C steel proved that there is a definite maximum solubility of C in the combined state in γ iron, the value of which depends on temperature. Transformer Tanks Constructed by Welding. JAMES LYALL. *Welding*, Vol. 3, June 1932, pages 373-374.

Some details of construction and welding procedure for welded tubular type transformer tanks. TEJ (11c)

Gas Welding as a Construction Means in Fokker Aircraft Design. (Das autogene Schweissen als Konstruktionsmittel im Fokker-Flugzeugbau.) H. LEHBERT. *Zeitschrift für Schweisstechnik*, Vol. 21, Oct. 1931, pages 228-238.

In the introduction, Fokker's adoption of welding in his airplane designs is historically reviewed. The welded fuselage as a whole as well as the single welded members as landing gear, rudders, engine mounting, etc., are fully considered and well illustrated. Next the difficulties associated with the welding performance in regard to the rather thin-walled tubes, to welding of differently gaged tubes and to non-destructive tests are critically discussed. The precautions during this kind of welding are summed up. Regarding the most suitable material, the importance of the yield point and weldability are considered. Touches upon the testing of welded aircraft parts and calls attention to the welding of non-ferrous metals and alloys also employed in airplane design. Elektron metal can be welded under certain precautions, while Al offers some difficulties with respect to the strength properties. Cu, brass and bronze are usually soldered. The advantages of welding adopted in aircraft construction are summarized as follows: low weight, simplicity and flexibility of design, unlimited possibilities in repair work, low costs due to mass production. EF (11c)

Welding of Pipe. S. LEWIS LAND (Heating & Piping Contractors National Association). *Journal American Welding Society*, Vol. 11, Mar. 1932, page 11.

A tentative outline for a course in pipe welding. TEJ (11c)

Electrodes and Plates for Pressure Vessels. E. DACRE LACY. *Welding*, Vol. 3, June 1932, pages 351-355.

The author discusses a report of welding investigations made by the British Engine Boiler and Electrical Insurance Co. Ltd. Etched sections of flanges welded on by the metallic arc, carbon arc and forge welding processes are shown and compared. Six different qualities of plate were welded, several types of electrodes being used. Although the use of a good flux coated electrode was found to be advantageous, bare wire may in some cases be preferable to a rod with an inferior covering. TEJ (11c)

The Advance of Electric-Arc Welding. EDWARD DACRE LACY. *Metallurgia*, Vol. 6, May 1932, pages 21-22.

Discusses applicability of welding to ship construction. Predicts extended use when ships are built. JLG (11c)

What does Gas Welding Promise in Bridge Construction? (Was verspricht die Acetylenschweissung im Brückenbau?) H. KRUSE. *Zeitschrift für Schweisstechnik*, Vol. 21, Dec. 1931, pages 281-286.

The favorable elongation and strength properties of oxy-acetylene welded seams with reference to the requirements in bridge construction are emphasized. The writer discusses at length, why a material reduction due to welding is secured and furnishes 2 instructive examples in which savings in material of 13 and 25% respectively were attained by the adoption of welding. Furthermore, inaccurate fitting-together during assembling can easily be eliminated, a greater flexibility from an architectural view-point is possible, simple performance of repair work or later reinforcements, and short times of erecting are the more outstanding advantages of welding. Further examples showing the possibilities of welding in regard to bridge construction are given with the object of revealing the new ways opened by this method of joining. The development of new profiles more suitable for welding are foreseen. EF (11c)

Savings in Maintaining Rail Systems by Means of the Welding Torch. (Ersparnisse bei der Instandhaltung von Eisenbahn Geleise Anlagen mit dem Schweissbrenner.) C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Jan. 1931, pages 8-9.

Article critically discusses 3 recent publications on the subject: first that of Tracy stating that gas-welding proved to be materially cheaper than electric-welding for building up battered ends of rails, the average ratio being $0.81 to $2.10 for each welded rail end. The most economically electric-welded rail end amounted to $1.17. With reference to a paper of Titger (*Mitteilung des Neuen Internationalen Verbandes für Materialprüfung*) the writer denies that the gas welding requires 2.2 m.³ oxygen and 1.9 m.³ acetylene per 1 kg. welding material. One m.³ of both gases is sufficient, the welding time being half an hour. Regarding a paper of Schmitt (same reference) a decided superiority of gas welding is claimed. EF (11c)

Some New Suggestions Concerning Welded Vessels and Tubes. (Einige neue Gedanken für geschweisste Gefässe und Röhre.) C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Apr. 1931, pages 73-75.

The new method of increasing the strength of a welded boiler with longitudinal and circumferential seams is characterized by the use of a continuous longitudinal strap outside of the shell right on top of the original longitudinal seam. This method of strengthening by a strap can also be applied to tubes and to joints of tubes among each other. EF (11c)

Electric Arc Welding in Ship Construction. J. FOSTER KING & JAMES MONTGOMERIE. *Welding Journal*, Vol. 29, Mar. 1932, pages 83-86, 89.

From an abstract of a paper read before the Institution of Naval Architects, Mar. 16, 1932. The authors briefly relate the history of arc welding as applied to ship construction and give physical properties of deposited weld metal. With good electrodes and proper procedure, weld metal shows 25 tons/in.² T.S. or more and 16 to 18% elongation. The key to good welding is proper relationship between current, size of electrode, mass of material adjacent to the joint, rate of deposition from the electrode and length of run made with each electrode. Proper fit-up is essential and proper inspection is the most important factor in the success or failure of electric welding. Includes discussion. TEJ (11c)

—

Change of A Rolling Mill Housing with the Aid of Electric Arc Welding. (Änderung eines Walzenständes mit Hilfe der elektrischen Lichtbogenschweissung.) K. JURCZYK. *Elektroschweissung*, Vol. 3, Feb. 1932, pages 33-36.

1 The paper gives an interesting example of the application of electric arc welding in increasing the width of a rolling mill housing. The welding offered no difficulties though the parts to be welded had a width of 100 mm. GN (11c)

Magnetic Influence on Electric Welding. J. E. KENNARD. *The Welder*, Vol. 3, Feb. 1932, pages 27-28.

— Sputtering and blowing of the electric arc occurs fairly frequently and is mostly due to magnetic influence; magnetic fields are set up by the welding current passing through the electrode, the arc and the work, the direction of the magnetic field depending on the direction of the current. The influence of the magnetic field can be reduced greatly by

2 properly placed backing plates or cross pieces of steel to provide better conditions of magnetic reluctance in magnetic paths and get steadier welding conditions. Ha (11c)

The Replacement of Castings by Gas-Welding in Machinery. (Die autogene Schweissung im allgemeinen Maschinenbau an Stelle der Giesserei.) C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Nov. 1931, pages 253-259.

— The handicaps of castings in regard to the properties of the casting material, to restrictions of design and to complicated making of the pattern and the casting are pointed out. Tests performed in the Eidgenössische Materialprüfungsanstalt, Zürich, yielded for material welded with a low

3 carbon welding rod: elasticity coefficient = 2,150 t./cm²., proportional limit = 2.2 t./cm²., yield point = 2.45 t./cm²., tensile strength = 3.9-4.2 t./cm²., mean elongation = 24%, quality factor = 0.95. Savings of material up to 50% by replacing castings by welded steel are reported. The frame of a surface grinding machine, stamping machine, and gear

— wheel cutting machine are shown in cast iron and in welded construction. The other illustrations refer to supplementary parts of machinery, to cases of gasoline supply pumps, milling, filing, grinding machines, frame of a hack-saw, under-frame of a butcher shop equipment, drilling machine

4 and a large steel valve. In conclusion the author critically discusses and denies the lower rigidity of welded machinery in comparison with castings. EF (11c)

Gas Welding of Long Vessels. (Die autogene Schweissung von langen Kesseln.) C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Dec. 1931, pages 286-290.

— Saving of 25% on pressure vessels up to 200,000 liters capacity due to welding are reported. The single steps of the operator's welding performance on such large units including detailed instructions on the making of the manhole, are covered. EF (11c)

5 **Up-to-date Equipment of an Oxy-Acetylene Welding Shop. (Moderne Einrichtung einer Acetylen Schweisserei.)** C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Mar. 1931, pages 50-54.

— Looks first into the more recent viewpoints concerning the most favorable gas pressure, the generation of the acetylene pressure, the utilization of a pressure reducing valve, and the kind of oxygen supply. The balance of the paper pertains to a detailed description of the various features of a modern gas-welding shop. The characteristics of the author's proposals are (1) the acetylene pressure is increased to 1-1.5 atmospheres, (2) a centralized oxygen supply. EF (11c)

6 **Up-to-date Installation of a Welding Shop. (Moderne Einrichtung einer Schweisserei.)** *Zeitschrift für Schweisstechnik*, Vol. 21, May 1931, pages 100-107.

Two critical discussions on a previous paper of Keel (see abstract above). The first author lays stress on an equal

— pressure of O_2 and C_2H_2 and shows an automatic regulator for this purpose. Advantages claimed: the flame need not be adjusted by the welding operator, since the pressure in both gas pipe lines is regulated in a central station. The flash back of the flame is entirely eliminated. The greater economy of the "Uniform Pressure System" is considered

7 at length, based on appreciable savings in time, gas, wages (unskilled operators can be employed). The efficiency of oxy-acetylene welding shops has been increased by 30 % due to this centralized pressure regulation. The second writer in the discussion calls attention to the constant pressure welding equipment of the Carba A. G., Bern, Switzer-

— land, incorporating the principles outlined in Keel's article. EF (11c)

Repair Welding on Cast Iron Water Hydrants. (Reparaturschweissungen an gusseisernen Strassenarmaturen der öffentlichen Betriebe.) H. JÜRGENS. *Gas- und Wasserfach*, Vol. 75, Feb. 6, 1932, pages 108-110.

8 Discusses the methods, materials, and kinds of welds used in repairing water hydrants in Mannheim, Germany. MAB (11c)

Fusion Welding with a High Pressure Mixture of Acetylene and Illuminating Gas. (Autogen-Schweissen mit einem Hochdruckgemisch von Azetylen und Leuchtgas.) E. KALISCH & W. GIUDICE. *Die Schmelzschweissung*, Vol. 11, Jan. 1932, pages 14-17; Mar. 1932, pages 49-51.

— In order to reduce the high cost of welding with pure acetylene, tests were made with a mixture of acetylene and city gas. With the usual low pressure in the gas mains no

9 satisfactory results were obtained but a compression to 3000 mm. water gage and a mixture of 1:1 of both gases gave a good result. Tests are described for welding of sheets from 2 to 14 mm. thickness which gave the same heat consumption and welding velocity with a saving of 10 to 15% against acetylene alone. Similar results were obtained for

— other ratios of gas to C_2H_2. An installation for this method is described. Microphotographs show the good condition of the weld. Ha (11c)

Comparison between Gas and Electric Welding Costs. (Kostenvergleich autogener und Elektrischer Schweissungen.) C. F. KEEL. *Zeitschrift für Schweisstechnik*, Vol. 21, Apr. 1931, pages

10 75-81.

An economical comparison between oxy-acetylene and arc-welding is fully detailed with reference to prices prevailing in Switzerland. The calculation, which of course is relative, discloses slightly greater cost for electric welding. EF (11c)

Gas Welding in Aircraft Construction. (Die Autogenschweissung im Flugzeugbau.) H. Haeberli. *Zeitschrift für Schweisstechnik*, Vol. 21, Mar. 1931, pages 54-58.

The progress in air-plane design due to the great economy and flexibility offered by gas welding technique is emphasized. Designing a joint connection in wood, steel tubes (two welded designs) and Duralumin (screwed and riveted) are compared, demonstrating the great possibilities of gas welding in aircraft construction. EF (11c)

Discussion of Paper on "Large Welded Everdur Pressure Vessels." Ira T. Hook & M. Powell. *Journal American Welding Society*, Vol. 10, Dec. 1931, pages 36-37.

Discussion of paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Paper published in the *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 39-47. See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA43. TEJ (11c)

Weld Ductility Requirements for Welded Pressure Piping. T. W. Greene. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 55-59.

Paper presented at the Annual Meeting of the American Welding Society in New York, April 1932. A ductility of 10% to 12% seems sufficient to meet all requirements of pressure piping. While ductility far exceeding this range can be readily secured in fusion welds, there appear to be no requirements in piping service which would justify the establishment of higher ductility specifications. Strength in the weld metal equivalent to the base material and freedom from imperfections are of far more importance than relative high ductility. TEJ (11c)

A Study of the Transformation Points of Fusion Welded Metal. F. R. Hensel & E. I. Larsen. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 28-32.

Paper presented at the Annual Meeting of the American Welding Society in New York, April 1932. By means of dilatometer readings, A_3 transformation points were determined for bare wire weld metal, coated wire weld metal, atomic hydrogen weld metal, oxy-acetylene weld metal, ingot iron and other steels of varying N content. It was found that: (1) Increasing the N content in the weld metal causes, (a) lowering of the A_3 transformation point, (b) increase in temperature range of α-γ transformation, (c) changes in expansivity above 600° C. (2) The magnetic transformation point is not appreciably affected by a variation of the N content in the weld. (3) The transformational characteristics of various types of weld metal are so altered by a severe hydrogen anneal that they become similar to those of pure Fe. TEJ (11c)

Spot Welding of Stainless Steel as Applied to Aircraft. Carl De Ganahl. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 60-62.

Paper presented at the Annual Meeting of the American Welding Society in New York, April 1932. Cold rolled 18-8 strip having a tensile strength of 175,000 lb./in.^{2} and 10% elongation is fabricated into airplane structure by spot-welding. Carbide precipitation is prevented by carefully adjusting electrode pressure, current and time of current flow. TEJ (11c)

Welding on U. S. S. New Orleans. J. O. Gawne. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 9-22.

Paper presented at the Annual Meeting of the American Welding Society in New York, April 1932. The author discusses the welding being done in the construction of U.S.S. New Orleans, a vessel of 10,000 tons standard displacement. Welding is used in construction of bulkheads, decks and platforms, shell, inner bottom, longitudinals, transverse framing, deck erections, fittings, foundations and auxiliaries. Most of this is direct current arc welding, both bare and heavily coated electrodes being used. Design values for weld metal are 36,000 lb./in.^{2} in tension and 29,000 lb./in.^{2} in sheer. Recent developments making possible welds in medium steel with tensile strength of weld metal superior to and elongation equal to that of the base metal, remove many of the design difficulties in the way of an all-welded war vessel. TEJ (11c)

The Uses of Carbon in Arc Welding. K. L. Hansen. *Welding*, Vol. 3, Apr. 1932, pages 222-225.

A discussion of the applications of arc welding where carbon constitutes one or both of the electrodes. Includes filling in blow holes in castings, description of the Electronic Tornado process and the carbon arc torch. The carbon arc is particularly adaptable for the welding of Cu and its alloys. TEJ (11c)

Welding as Applied to the Electrolux Refrigerator. W. R. Campbell & R. S. Taylor. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 48-52.

Paper presented at the Annual Meeting of the American Welding Society in New York, April 1932. Description of the construction and manufacture of an absorption type household refrigerator unit. There are 78 individual welds in each unit making a total of 150 inches of welding in steel ranging from 17 to 11 gage. Most of the welding is done by the oxy-acetylene process, the welds being made while the parts are moving on a conveyor. TEJ (11c)

Welding of Tool Steels. (Les Aciers à outils et la Soudure.) C. Franche. *Aciers Spéciaux, Métaux et Alliages*, Vol. 7, Apr. 1932, pages 147-149.

Brazing and welding of tool steels is briefly discussed. GTM (11c)

Fusion Welding in Steel Structures. (Die Autogen-Schweissung im Stahlbau.) E. Greger. *Die Schmelzschweissung*, Vol. 11, May 1932, pages 100-104.

The construction of a factory building of 87 m. length, 25 m. width and 9.14 total height welded together and the details of design with the procedure of assembling is described and illustrated. Tests made on the joints showed almost the same strength as the parent material. Ha (11c)

Welded Storage Tanks. Orville Adams. *Welder*, Vol. 3, Apr. 1932, pages 25-30.

Welded Barge Construction at Federal Shipbuilding and Dry Dock Company. Gordon G. Holbrook. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 5-8; *Welding*, Vol. 3, May 1932, pages 285-289.

1 Paper presented at the Annual Meeting of the American Welding Society, in New York, April 1932. A description of an all-welded steel barge design which may be built at a price competitive with wooden construction. The outstanding advantage of the welded barge over the barges of conventional riveted construction lies in the absence of rivets to become loosened, leak and corrode away. 67 to 80% of the welding is done by the automatic shielded carbon arc process. The basic principle of this design is the joining of rolled structural channels with intermediate flat bars, all united with a double seam of electric welding. TEJ (11c)

Rules and Regulations for Electrically Welded Steel Construction in Germany. P. V. Jankov. *Journal American Welding Society*, Vol. 11, Mar. 1932, pages 29-30.

2 New rules on welded steel construction have been published under the title "Vorschriften für geschweisste Stahlbauten." Explanations to these rules with examples for calculation of welded construction have also been prepared by Dr.-Ing. O. Kommerell and published by Wilhelm Ernst & Sohn. Results of a few tests of welded joints are included. TEJ (11c)

Cutting with Oxygen. (Oxycoupage.) L. de Jessey. *L'Usine*, Vol. 41, Jan. 11, 1932, page 31.

3 A brief review of the changes taking place in the zones in and near a cut made with the oxygen flame. Micrographic examinations show that the thickness of the tempered zone is not more than 1 mm., that of the transition zone 2 mm. The mechanical properties of a metal cut with oxygen are about the same as a metal worked with tools. An after-treatment is not necessary for mild steels. Ha (11c)

Ductility and Penetration—Two Fallacies. C. J. Holslag. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 47-48.

4 Paper presented before the Annual Meeting of the American Welding Society in New York, April, 1932. The author believes that enough ductility must be obtained in weld metal to withstand the welding contracting strains, but beyond this it is foolish to go. Penetration in steel other than enough to get good fusion is not desirable. TEJ (11c)

Descriptive History of Covered Electrodes. C. J. Holslag. *Industry & Welding*, Vol. 3, Mar. 1932, pages 22-24.

A short treatment of the reason for covering the welding pencil and the influence of the type of covering on the weld. Ha (11c)

What the Welding Industry Must do to Receive Engineering Acceptance. S. C. Hollister. *Welding*, Vol. 3, May 1932, pages 298-300, 324.

5 Paper presented before the Thirty-second Annual Convention of the International Acetylene Association. It is the author's opinion that stress distribution and fatigue under repetitive loading are fundamental subjects upon which engineering research must concentrate before welding is generally applicable to engineering structures. An adequate method of field inspection is necessary. TEJ (11c)

Constructing a 500-Gallon Welded Everdur Tank. C. B. Jacobs, Jr. *Journal American Welding Society*, Vol. 11, Mar. 1932, pages 17-18.

6 Everdur, a readily weldable Cu-Si-Mn alloy possessing the strength of mild steel and having the general corrosion resistance of Cu, is increasing rapidly in use as a tank material. The author describes the procedure used in metallic arc welding of a large Everdur hot water storage tank. TEJ (11c)

The Welding of Bi-Metal. (Ueber Schweissung von Bimetall.) Hans A. Horn. *Autogene Metallbearbeitung*, Vol. 25, May 15, 1932, pages 145-147.

7 Welding of a bi-metal (composed of a layer of a noble metal united to a base metal by pressure welding and then rolled to the desired thickness) to a similar or different piece of metal was investigated. Recently a third layer is placed between the 2 forming the actual bi-metal in order to maintain the purity of the nobler metal during heating; this third layer has a higher melting point than the 2 other metals. It was found that welding of both sides of the bi-metal is not feasible. The Ag is best welded with Ag and the Cu hard-soldered with an easily flowing flux. In general, it is rather difficult to make a perfect weld with such double or triple metals. Ha (11c)

Modern Spot and Relief or Projection Welders and Their Application to Production Problems. P. W. Fassler. *Journal American Welding Society*, Vol. 11, May 1932, pages 12-15.

8 Paper presented before the Annual Meeting of the American Welding Society in New York, April 1932. The author traces the development of spot welders and describes the modern spot welding machine. The theory of relief or projection welding and the major variables for a given welding problem are discussed. TEJ (11c)

Why Ductility of Welds is Important in Welded Pressure Vessels. E. R. Fish. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 32-33; May 1932, pages 25-26.

9 Paper presented at the Annual Meeting of the American Welding Society, April 1932. The author is of the opinion that ductility in weld metal is highly desirable, if not absolutely necessary to assure welds, the integrity of which can be depended on with reasonable certainty. TEJ (11c)

Measuring Methods and Measurements in Electric Arc Welding. (Messmethoden und Messungen bei der elektrischen Lichtbogenschweissung.) P. Flamm. *Elektroschweissung*, Vol. 3, Mar. 1932, pages 50-52.

A new acoustic method has been developed by the author which permits accurate study of the course of welding. Experiments were carried out to test the new apparatus practically. The behavior of various electrodes has been studied under a great variety of conditions. GN (11c)

10 **Electric Arc-Welded Ships' Watertight Transverse Bulkheads.** Stanley E. Evans. *Welder*, Vol. 3, Apr. 1932, pages 4-7.

The points to be taken into account in their design are explained and the angle, bulb angle or channel sections used in their construction are described. A diagram for the proper selection of the materials is added. Ha (11c)

Arc-Electric Welding of Aluminum (Ueber das bogenelektrische Schweissen Aluminium). M. Zack. *Aluminium, Hauszeitschrift V.A.W. und Erftwerk,* Vol. 4, Mar. 1932, pages 75-76.

A new method of welding Al with 3-phase current is described. 2 electrodes are used, one serves mainly for preheating the piece and the other for welding. The welding generator supplies current of 200 to 250 cycles as hereby the arc is more constant than with the usual low frequency; one phase is connected to the piece, the second to a carbon electrode for preheating and the third to an Al-rod for welding. This arrangement gives 3 arcs (joined to a common neutral point) which are independent of each other. The difference between the arc-electric welding and gas welding is that in the former the heating is only local while in the latter a more extended area is heated; this must be taken into account by the welder. Ha (11c)

Sheet Lead Welding Procedure. *Sheet Metal Worker,* Vol. 23, Mar. 18, 1932, pages 124-126, 132.

The various working methods of lead-burning or lead-welding are discussed and illustrated by examples of tank linings and architectural uses, as roofing, spandrels, ornamentation, etc. Ha (11c)

Electric Arc-Welding in the Construction of Buildings in Italy. *The Welder,* Vol. 3, Feb. 1932, pages 14-17.

Technical and economic reasons compelled the evident application of electric welding for large structures as well as for small residence buildings in Italy. Ha (11c)

Gas-Welded Ships on Lake Geneva. (Autogen geschweisste Schiffe auf dem Genfersee.) *Zeitschrift für Schweisstechnik,* Vol. 21, Aug. 1931, pages 182-184.

Diesel engine powered ferry boats of 24 m. length assembled by oxy-acetylene welding are described and illustrated. EF (11c)

Bronze Welding Locomotive Cylinders and Frames. *Welding,* Vol. 3, Jan. 1932, pages 13-14.

Article from data furnished by Air Reduction Sales Co. Tabulation of repair costs of 2 jobs show considerable saving by use of the oxyacetylene welding process. TEJ (11c)

Hard Surfacing Reduces Machinery Maintenance. Francis A. Westbrook. *Welding,* Vol. 3, June 1932, pages 355-360.

A number of hard-surfacing applications on mining and crushing machinery. TEJ (11c)

Gas Welded Mine Buggies. (Acetylengeschweisste Gruben Förderwagen.) *Zeitschrift für Schweisstechnik,* Vol. 21, Apr. 1931, pages 70-72.

The weight of mine buggies is greatly reduced, their stability materially improved, the repair work expenses cut from 18 Groschen to 8 Groschen due to the application of welding instead of riveting. Owing to the rugged service in mines the loosening of rivets in former buggies was the source of much trouble. A new design of welded carriages is illustrated. The frame can also be welded. The reduction in weight amounts to 15%. A table is included compiling all the expenses for making a gas-welded and a riveted buggy. The ratio is 362.96 Zloty to 403.94 Zloty in favor of welding, or a saving of 11%. EF (11c)

Welding in Shipbuilding. (Schmelzschweissung im Schiffbau.) *Werft, Reederei, Hafen,* Vol. 12, May 15, 1931, pages 164-166.

General. WHB (11c)

Adoption of Welding Codes Is Stamp of Acceptance. *Steel,* Vol. 90, Jan. 4, 1932, pages 160-161, 170.

The adoption of codes by the various engineering and welding societies approving the fusion welding of unfired pressure vessels and power boilers has given an impetus to structural welding in general. Improvements in welding technique and welding tests, the production of better welding wire, and the perfection of a superior type of heavily-coated electrodes have made possible the production of welds possessing high ductility and high resistance to corrosion. Wider use of welding is anticipated in building construction, shipbuilding, aircraft construction, pipe line construction and other fields. JN (11c)

Gas-Welded Columns Made Up of Shapes. (Autogengeschweisste Säulen aus Profileisen.) *Zeitschrift für Schweisstechnik,* Vol. 21, Oct. 1931, pages 238-241.

Goes into great detail in regard to making columns of shapes joined by welding and illustrates the incorrect and proper accomplishment of the welding operation. A wider use of welding for this purpose is predicted if the multiple flame torch is employed in the making of V-seams and butt seams. The information is based on tests carried out in the Schweisstechnische Lehr und Versuchsanstalt des Österreichischen Acetylenvereins Wien. EF (11c)

The Admissible Straining of Gas Welded Seams. (Die zulässige Beanspruchung von autogenen Schweissnähten.) *Zeitschrift für Schweisstechnik,* Vol. 21, Mar. 1931, pages 58-59.

Urges the substitution of the more up-to-date safety coefficient 0.7-0.8 for the present one of 0.5-0.6 on account of the recent progress of gas welding in case of sheets of 6 mm. thickness and above. Advocates the omission of hammering and annealing of welded seams. The utilization of strengthening straps is accompanied by new stresses. However a ridged (Verdickung) seam is recommended and if a welded rod of greater strength is applied, strength of seam amounts to 0.7-1.0 strength of welded sheet. EF (11c)

Welded Steel Constructions. (Geschweisste Stahlkonstruktionen.) *Zeitschrift für Schweisstechnik,* Vol. 21, Nov. 1931, pages 261-262.

The riveted framework of a continuous silver plating bath is compared with one which is welded. EF (11c)

Stresses Set Up in Cutting and Fusion Welding. (Spannungen beim Brennschneiden und Schmelzschweissen.) *Zeitschrift für wirtschaftliche Fertigung,* Jan. 1932, pages 10-11.

General discussion. GN (11c)

Tests on Welded Seams with Strengthening Straps. (Versuche an Schweissnähten mit Verstärkungslaschen.) *Zeitschrift für Schweisstechnik,* Vol. 21, Aug. 1931, pages 175-177.

Data are reported from tests carried out in the Eidgenössische Materialprüfungsanstalt on samples cut from welded sheets which were provided with a strengthening strap. It is remarkable that fracture exclusively occurred with all samples at some distance from the seam, thus proving that the strength of the welded sheet can be insured by welding methods. A small pressure vessel provided with a "covered longitudinal seam" is discussed and illustrated. EF (11c)

Fusion Welding of the Aluminum Alloys. Wm. Rogerson. *Industry & Welding,* Vol. 3, Apr. 1932, pages 24-30; May 1932, pages 22-26, 32.

1 The most widely used process for welding Al and its alloys is the oxy-hydrogen or oxy-acetylene method. The equipment required is described. The proper selection of flux is of greatest importance. It must possess the following characteristics: It must melt at a temperature just slightly below Al; in the molten condition it must quickly dissolve or break up the Al oxide with which it comes into contact; the specific gravity of the molten flux containing the Al oxide must be sufficiently below that of the molten Al to insure that it quickly rises to the surface of the weld carrying out all impurities. It must be stable under the temperatures employed and should not deteriorate with age, nor be too deliquescent. The methods of applying the flux, the proper size of welding pencils, handling of the flame and preparation of the seams, are fully explained. Part II. Discusses the care that must be taken in order that the welds be successfully completed without distorting the original shape of the casting; the method is described and it is further explained how to clean and finish the weld. The appearance of a weld in a micrograph is explained. The arc welding of Al, preparation of the piece and electrodes to use are discussed. Ha (11c)

Ductility: A Measuring of Cleanliness. E. Chapman. *Journal American Welding Society,* Vol. 11, May 1932, pages 29-32.

3 Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author shows, by means of photo-elastic studies, stress distribution in various types of welds, explaining why a clean, ductile weld metal is necessary for highly stressed parts. TEJ (11c)

Introducing Welding into a Structural Fabricating Shop. Paul B. Covey. *Welding,* Vol. 3, Apr. 1932, pages 231-233, 256-257.

Some problems to be encountered in (1) estimating, (2) design and detailing, (3) fabrication, (4) inspection of welded structural steel, and suggestions as to how they may be solved. TEJ (11c)

Crawler Tractor Construction Improved by Welding. L. R. Canfield. *Welding,* Vol. 3, May 1932, pages 296-297; *American Machinist,* Vol. 76, Feb. 11, 1932, page 224.

4 Description of some welded tractor parts and discussion of the advantages of welded construction. Ha+TEJ (11c)

Fundamentals of Electric Resistance Welding. (Grundlegendes über die elektrische Widerstandsschweissung.) W. Brueck. *Elektrowärme,* Vol. 2, Apr. 1932, pages 89-91.

The 3 kinds of electric welding methods, butt welding, spot welding and seam welding, are discussed in their different modifications, their proper fields of application, the preparation of the pieces and a few examples are given for comparison with flame welding; especially in chain welding great savings can be made by electric welding. Ha (11c)

5 **British Practice in Welding of Steel Structural Work.** James Caldwell. *Welding Journal,* Vol. 29, May 1932, page 140; *Iron & Coal Trades Review,* Vol. 124, May 27, 1932, pages 880-881.

Summary of a paper read before the International Association for Bridge & Structural Engineering, Paris Congress, May 1932. Welding by means of the oxy-acetylene blowpipe has not met with much support in Great Britain for the assembly and the reinforcement of steel structures, but electric arc welding has developed into general practice. Ha+TEJ (11c)

How Welding Revolutionized a Fast Growing Industry.

6 Ernest D. Chabot. *Welding,* Vol. 3, Apr. 1932, pages 220-221.

Because of the many advantages of this type of construction, the steel frames for greenhouses are now practically all welded despite former opposition by florists and growers. TEJ (11c)

Should Metal Work in the Decorative Arts be Fusion Welded? (Sollen kunstgewerbliche Metallarbeiten autogen geschweisst werden?) Hans Casse. *Die Schmelzschweissung,* Vol. 11, Apr. 1932, pages 70-71.

The question is emphatically answered in the affirmative and several examples illustrate the trend. Ha (11c)

7 **Redesigning Fitted Pipe Lines for Welding.** A. L. Byfield. *Welding,* Vol. 3, May 1932, pages 311-314.

Redesigning screwed and flanged pipe lines for welding has been characteristic of the last 2 or 3 years during the transition period from fittings to welded joints. Many pieces are eliminated and much weight saved through the application of manufactured welded pipe fittings. TEJ (11c)

The Distribution of Stress in Fillet Welds. G. N. Borrow. *Welder,* Vol. 3, May 1932, pages 33-36.

The different forms in which a fillet weld can be made are discussed and 6 papers referred to for the calculation of the stresses. Ha (11c)

8 **Use of Welding in Plate Fabrication.** T. F. Bright. *Journal American Welding Society,* Vol. 11, Mar. 1932, pages 5-10.

Paper presented at the Jan. 8th meeting of the Chicago Section of the American Welding Society. Discussion of the transition from riveted to all-welded gas holders and the relative merits of the caulk welded and tool caulked joints. It is believed that the provision for caulk welding in the A.S.M.E Fusion Welded Code for Unfired Pressure Vessels should be revised. The author gives his experience in changing over from bare to covered electrodes and suggests a way to accomplish this change. Test procedure for new electrode is given. TEJ (11c)

9 **Some Limiting Factors in Metallic Arc-Welding.** E. V. Boorne. *Welder,* Vol. 3, Apr. 1932, pages 18-20.

The means by which arc-welding, and particularly manual welding, may be speeded up to reduce manufacturing costs is discussed. The only means would be the application of higher currents, either with higher current densities in the usual electrodes of No. 4 S.W.G., or with larger electrodes of ¾" to 1" diameter. The nature of the metal to be welded is an important factor in this as great metallurgical changes due to the greater heat produced must be avoided. A higher degree of heating would also result in a more rapid degree 10 of cooling and would have a harmful effect on the grain structure which can only be remedied by a process of normalizing which in practice would usually be impracticable. Speeding up the welding process is therefore connected with certain dangers which in every case should be given most careful consideration. Ha (11c)

Ductility in Metal Structures. C. A. ADAMS. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 46-47.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author discusses ductility of metal, particularly weld metal and stresses the importance of obtaining weld metal having a certain amount of ductility. For many types of structure high ductility is not essential. Our knowledge of the importance of ductility is very limited. Further research in this field is necessary. TEJ (11c)

Duralumin Tanks with Riveted Joints—Comment. F. V. HARTMAN. *Machinery,* Vol. 38, Jan. 1932, page 398.

Discussion of "Points on Making Duralumin Tanks with Riveted Joints" published in *Machinery,* Oct. 1931, page 135. Duralumin sheets used in aircraft work are always heat-treated to improve their mechanical properties and also their resistance to corrosion. Al tanks do not corrode at welded joints if properly welded. Rivets should be heat-treated. They should be driven before they age. RHP (11d)

The Effect of Ductility on Security in Welded Connections—Methods of Its Measurement. D. ROSENTHAL. *Journal American Welding Society,* Vol. 11, May 1932, pages 5-9.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. Overstressing may occur in a welded joint during the shrinkage following fusion or under applied loads in service. The author describes notch tests and X-ray diffraction patterns of welds varying in ductility. To prevent overstressing, both the parent and deposited metals must be ductile. The more ductile they are, the safer the structure. The notch test seems to be the most suitable for measuring the effect of overstressing in welds. TEJ (11c)

Automatic Resistance Welding Machines. (Selbsttätige Widerstand-Schweissmaschinen.) E. RIETSCH & S. SANDELOWSKY. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Apr. 9, 1932, pages 375-376.

Describes construction and operation of a few modern automatic welding machines of the A E G—Berlin. Ha (11c)

The Arc Welding of Structural Steel. J. H. PATTERSON. *Welding Journal,* Vol. 29, May 1932, pages 147-148; *Welder,* Vol. 3, Apr. 1932, pages 8-15.

Paper read before the Institution of Welding Engineers, London, March, 1932. The paper discusses the reasons for the growth of arc-welding, its weakness, the precautions necessary for welding practice and special problems encountered. The regulations issued by the British Corporation of Welders require the following standards of mechanical behavior of the weld metal: tensile strength 26-29 tons/in.^{2}, elongation 16-20% in 8 in., bend 120° on a standard test piece without showing surface flaws, impact value of 20-35 ft.-lb., and fatigue limit 11-13 tons/in.^{2} A few examples of tests made on building structures are cited. TEJ+Ha (11c)

The Welding of Copper with the Oxy-Acetylene Flame. L. C. PERCIVAL. *Welding Journal,* Vol. 29, Apr. 1932, pages 102-104; *Industrial Gases,* Vol. 13, Mar. 1932, pages 5-9.

Paper read before the Members of the North-Western Branch of the Institution of Welding Engineers, March 15th, 1932. After a brief outline of the metallurgy and physical properties of Cu, the author describes proper Cu welding procedure. The welding rod is of deoxidized Cu. A neutral flame is used and a suitable flux is necessary. Ordinary Cu contains a small amount of copper oxide which is detrimental to good welding. Advantages of Cu and Cu welding are cited. Includes discussion. DTR+TEJ (11c)

Ductility: What is Its Significance? How Test for It? H. F. MOORE. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 35-36; discussion, May 1932, page 26.

Paper presented at the annual meeting of the American Welding Society in New York, Apr. 1932. Discusses the mechanism of failure of metals due to repeated stress. It is highly necessary that welded joints, including the weld metal, the base metal and the metal in the junction zone, should be ductile. It is necessary that the metal should have ordinary ductility for steady loads and to withstand the strains of erection, and as the use of welding is extended to pressure vessels, tall buildings, railway structures and some machine parts, it is becoming increasingly necessary that welds should have "crackless plasticity." TEJ (11c)

A Welding Magna Charta. H. M. PRIEST. *Industry & Welding,* Vol. 2, Oct. 1931, pages 2-6.

Report of the American Bureau of Welding. See "Strength of Structural Welds," *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 42. Ha (11c)

Load Chart for Fillet Welds. V. A. PRINCE. *The Welder,* Vol. 3, Feb. 1932, pages 34-36.

A chart is given for the determination of allowable loads per inch of fillet welds without resorting to the necessity of obtaining the throat dimension and making the subsequent calculation. The chart shows the loads for fillets from ⅛ to ½". Ha (11c)

Arc Welding Oil and Gas Pipe Lines. HAROLD C. PRICE. *Welding,* Vol. 3, May 1932, pages 315-317.

The author gives some interesting data based on experience of arc welding over 1000 miles of steel pipe. TEJ (11c)

Thyratron Control for Resistance Welding Machines. SAMUEL MARTIN, JR. *Welding,* Vol. 3, May 1932, pages 293-295; June 1932, pages 361-363, 366.

Thyratron tubes used as current interrupters for continuous spot welding give a greater number of interruptions per minute and do away with contacts or moving parts in the power lines. The author describes the general theory and characteristics of the thyratron tubes and their application to resistance welding. Part II. With the aid of wiring diagrams, the author explains the operation of thyratron tubes as applied to current control in resistance welding. Oscillograms show results obtained. TEJ (11c)

Mechanical and Physical Properties of Weld Metal. J. H. PATTERSON. *The Welder,* Vol. 3, Feb. 1932, pages 6-10.

The harmful influence of oxygen and particularly nitrogen in welds when made with bare wire electrodes is shown in curves from tests made by several authors; to eliminate this harmful influence coated electrodes are now universally used. The mechanical properties of welds made with different kinds of coated electrodes are given in a table. Ha (11c)

Oxy-Acetylene Welding and Cutting. STUART PLUMLEY. University Printing Company, Minneapolis, 1931. 2nd edition. Cloth 7½ x 11 inches, 410 pages. Price $5.00.

The purpose of the book is two-fold in that it is a manual for instructing the beginner in the operation of the oxy-acetylene torch regulators, cylinders, in general equipment, and a course of instruction for the beginner in welding various classes of metals. It is also an instruction book on the best methods for welding carbon and alloy steels and all metals of the non-ferrous group such as aluminum, copper, nickel, etc. Plant lay-outs and the details of generator design are shown, also job shop cost systems and instructions in the managerial side of job shop welding. Other items of interest include lead burning methods of building up surfaces for resistance to wear, methods for cutting copper and alloys, and other miscellaneous data. The important part of codes relating to welding as applied to boilers and pressure vessels such as the A.S.M.E., Department of Commerce, Underwriter's Rules, etc. are given. Also the methods adopted for welding tanks, pipe lines and aeroplane parts are described and illustrated. A great deal of valuable information covered by tables is also included.

C. A. McCune (11c)-B-

Welding Torches with Several Flames. (Schweissbrenner mit mehreren Flammen). E. ZORN. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Apr. 24, 1932, pages 225-226.

A welding torch has to fulfill the following purposes: (1) preheating of the base material, (2) melting of the base metal, (3) preheating of the filling material, (4) melting of the filling material. Since a welding torch has to fulfill these procedures simultaneously its efficiency is impaired; therefore, welding torches have been devised which are equipped with several flames to effectively meet the above requirements. There are described welding torches with several flames as constructed by the Griesheim Works of the German Dye Trust. There is in particular pointed out that such welding torches essentially increase the velocity of welding. Examples as to the successful application of such torches are given. The historical development of torches with one or several flames is briefly sketched. GN (11c)

A Reply to the Discussion on Paper by Wilmer E. Stine on "Factors Affecting the Weldability of Steel." W. E. STINE. *Journal American Welding Society,* Vol. 11, Mar. 1932, pages 18-20.

Stine's paper was presented at the 1931 Fall Meeting of the American Welding Society and was published in the Journal of the American Welding Society, Vol 10, Sept. 1931. The author explains more fully some of the points mentioned in his paper and answers some of the criticisms. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 71. TEJ (11c)

Comments on Reply by Mr. W. E. Stine to the Discussion of His Paper on Factors Affecting the Weldability of Steel. F. T. LLEWELLYN. *Journal American Welding Society,* Vol. 11, Mar. 1932, page 20.

Llewellyn defends his previous statements made in his original discussion of Stine's paper. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 71. TEJ (11c)

Standards for the Pipe Welding Industry. JOHN ZINK. *Industry & Welding,* Vol. 3, Mar. 1932, pages 6-11.

Directions are given for fillet welds and miter welds; throat thickness, fusion width and shape are specified; a fillet weld should be designed not only to close or fill-in a void, but as a strength weld. This type of weld is useful for the manufacture of auxiliary assemblies such as pipe hangers, supports, etc. Ha (11c)

Testing of Electrical Welds and Usefulness of Shielding Welding Rods in the Ehn's Cementation Test. (Prüfung elektrischer Schweissungen sowie der Brauchbarkeit der Ummantelung von Schweissstäben durch die Ehnsche Zementations Probe.) WERNER ZIELER. *Stahl und Eisen,* Vol. 52, Mar. 10, 1932, pages 236-239.

Effect of various atmospheres on normal structure of weld seam are discussed and it is demonstrated that those atmospheres which produce a good weld seam, also yield a normal cementation structure. Condensed summary of literature is given. Sufficient structure micrographs are included to show that Ehn's Cementation is a valuable means for testing weld seams as well as demonstrating usefulness of providing shielded atmospheres around electrodes. DTR (11c)

Welding Cast Iron Locomotive Cylinders. JAMES M. VOSSLER. *Welding,* Vol. 3, Apr. 1932, pages 217-219, 225; May 1932, pages 290-292.

With proper preheating and proper control of cooling, the deposited metal and the adjacent parent metal will be of the same degree of softness as the rest of the casting. To preheat properly, the casting must be enclosed in a properly built furnace. The author describes in detail the design and erection of such a furnace and also gives valuable pointers on preheating. Part II. The author describes the proper oxy-acetylene equipment to use, the welding procedure to follow and how to cool off the casting in order to consistently obtain good results. TEJ (11c)

Welding of Non-Ferrous Metals. (Schweissung von Nichteisenmetallen.) Symposium held by the Deutsche Gesellschaft für Metallkunde and the Fachausschuss für Schweisstechnik of the Verein deutscher Ingenieure. *Zeitschrift für Metallkunde,* Vol. 24, Jan. 1932, pages 11-22.

Welding of Copper. (Praxis der Kupferschweissung.) E. WEESE. Pages 11-15.

Report upon the tensile strength and elongation of Cu welds; repair of locomotive fire boxes; all-welded fire-boxes; Cu-welding in chemical industries; experiments in arc welding; influence of Mn; X-ray radiography.

Welding of Nickel. (Die Nickelschweissung.) C. CANZLER. Pages 15-18.

Gas welding of Ni; influence of Mn; "arcatom" welding; "arcogen" welding; welding of Monel metal; pressure welding; practical applications.

Autogenous Welding of Aluminum and Its Alloys. (Das autogene Schweissen von Aluminium und seinen wichtigeren Legierungen.) H. BUCHHOLZ. Pages 19-22.

Melting & Refining (12a)

Bessemer Process and its Product. RICHARD S. MCCAFFERY (University of Wisconsin). *Blast Furnace & Steel Plant,* Vol. 19, Nov. 1931, pages 1448-1450, 1454; Dec. 1931, pages 1566-1571; condensed in *Fuels & Furnaces,* Vol. 9, Nov. 1931, pages 1273-1276, 1292; *Engineering,* Vol. 133, Feb. 19, 1932, page 235. 1

Paper read before the American Iron & Steel Institute, Oct. 23, 1931. See *Metals & Alloys,* June 1932, page MA 178. MS (12a)

Experiments on the Production of Malleable Pig Iron in the Brackelsberg Furnace by the Use of HK-Special Pig Iron. (Versuche über die Herstellung von Temperrohguss im Brackelsbergofen unter Verwendung von HK-Sonderroheisen.) M. PASCHKE & K. LANGE. *Die Giesserei,* Vol. 19, Jan. 22, 1932, pages 23-27. 2

The principal characteristics of the HK-special pig iron are very high C content, low Si content and a very low content of metallic Al. This composition made it very suitable for the production of malleable Fe, and illustrations show the very clean and exact castings obtained with it, due to its fluidity. The amount of waste was considerably reduced by melting this HK-iron in the Brackelsberg furnace. Ha (12a)

Electric Steel Furnaces in Belgium. (Les fours électriques à acier en Belgique.) R. PITAVAL. *Journal du Four Electrique,* Vol. 41, Mar. 1932, pages 91-92. 3

With the small production (15,500 tons in 1930) of special steels Societe John Cockerill and Socite d'Ougree-Marihaye found it to be much cheaper to use basic convertor-electric furnace duplex process than to build open hearth furnaces for production of the same quality of metal. JDG (12a)

Consumption of Brickwork Lining and Changes in Operating Conditions During a Converter Run. (Ueber den Verschleiss der Ausmauerung und Aenderungen der Betriebsverhältnisse während einer Konverterreise.) J. POSTINETT. *Stahl und Eisen,* Vol. 52, Apr. 28, 1932, pages 405-409. 4

Report 228 of Steel Mill Committee of Verein deutcher Eisenhüttenleute. Includes discussion. Test results illustrate consumption of converter lining in the course of the run. Causes are both mechanical and chemical. The brickwork of the main converter shell is protected against wearing away by the practically motionless steel bath. Chief causes which eat up the lining are: (1) mechanical agitation; (2) chemical attack in horizontal position of converter charge on the finish blow, which is so much greater if the slag does not have an excess of lime; (3) air, passing up from the bottom over the bath in the horizontal position of converter, burns the tarry components of the back lining. Tar-dolomite mixtures were used for lining around tuyères and after being set on converter bottom, tar-dolomite was poured all around tuyères and bottom. The bottom when burned was 45 to 50 cm. and lasted 45 to 50 charges. Graphs are given showing converter volume, bath, blowing time, rotating cross-section and weight against number of charges. In order to improve operating conditions during the blowing period it is recommended that the lower section of the converter be enlarged, best into an approximate ball shape. The weight of converter may then be decreased, and this in turn reduces construction costs. DTR (12a) 5

Desulphurization of Cast Irons and Steels by the Means of Acid and Basic Slags. (La desulfurations de la fonte et de l'acier au moyen de laitiers acides et basiques.) A. POSSENTI. *Revue de Metallurgie,* Vol. 28, May 1932, page 287. 6

See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 18. JDG (12a)

Practical Hints in Melting Silumin. (Praktische Winke beim Schmelzen von Silumin.) *Zeitschrift für gesamte Giessereipraxis,* Vol. 53, Mar. 20, 1932, pages 125-126.

In melting silumin the following points are to be considered: (1) the raw material, (2) the melting process which is suitably done in crucible furnaces, (3) the refining process with sodium. For refining 25 kg. of silumin 18 g. of sodium are used. The sodium is enclosed in an Al foil which is dipped in the molten silumin till the refining process is completed. GN (12a) 7

The Open-hearth Furnace as a Melting Medium for Malleable Cast Iron. G. R. SHOTTON. *Foundry Trade Journal,* Vol. 46, Mar. 24, 1932, pages 195-196.

Deals with the construction of the open hearth furnace and the working methods employed in the manufacture of malleable cast iron. The use of such a furnace is rare in Great Britain due to its high cost of installation and also its high cost of production unless working near maximum capacity. OWE (12a) 8

Manganese Equilibrium in Production of Steel in the Open-Hearth Furnace and its Practical Application. (Das Manganglelchgewicht bei der Stahlerzeugung im Siemens-Martin-Ofen und seine praktische Anwendung.) EDUARD MAURER & WILHELM BISCHOF. *Archiv für Eisenhüttenweisen,* Vol. 5, May 1932, pages 549-557; *Ergebnisse der angewandten physikalischen Chemie,* (1), 1931, pages 109-197.

A review, summary and discussion of the literature on Mn equilibrium for both acid and basic steel methods. In the acid method the effect of SiO_2 and CaO, and in the basic method the effect of CaO, SiO_2, MgO, Al_2O_3, and P_2O_5 on the Mn equilibrium are given, as well as effect of temperature. In the 2 methods are summarized the relation between Mn content of the steel and amount of Mn in charge, composition and amount of slag. Values based on theory according to mass action law were compared with values found in practical operation and agreed well. Use of Mn equilibrium for red-short tests, rolling scrap, and physical properties of the steel was explained. 33 references. Ha + DTR (12a) 9

Partition of Manganese Slag to Steel. Correspondence from E. MAURER & W. BISCHOF, Freiberg, Germany. *Metal Progress,* Vol. 21, Mar. 1932, pages 66-68. 10

A report on research to determine variations in the value of $k = Mn(metal) \times Fe(slag)/Mn(slag)$ with variation in slag analysis for the reaction $FeO + Mn \leftrightarrow MnO + Fe$. Portions of equilibrium diagrams are reproduced. WLC (12a)

FINISHING COSTS
OFTEN START
IN THE LADLE

The demand today is not for price alone, but for *quality at a price.* The quality of your castings is reflected throughout the entire process of finishing — grinding, polishing, buffing, plating, etc.

When you add Ferro Carbon-Titanium at the ladle you assure your customers cleaner, more uniform, pit-free, finer-structure castings.

Show your customers why finishing costs often start in the ladle. Titanium Engineers will gladly adapt Ferro Carbon-Titanium to your operating conditions.

On the Origin of Non-metallic Inclusions in Steel. (Ueber die Enstehung von nicht metallischen Einschlüssen im Stahl.) F. Latta, E. Killing & F. Sauerwald. *Kohle und Erz,* Vol. 29, Mar. 1, 1932, pages 64-66.

In studying the origin of non-metallic inclusions in steel, the authors carried on experiments on the velocity with which inclusions of fire clay and open hearth slag ascenu in the steel bath. Furthermore, they examined the occurrence of inclusions which are caused by the deoxidation process. The results indicate that the velocity with which foreign particles ascend in the steel bath is rather considerable, provided they are not present as small flakes. The velocity of separation of foreign inclusions is high in particular when the foreign particles coagulate to larger aggregates. At least the particles of fire clay and open-hearth slag disappeared from the steel bath much quicker than is to be expected from Stokes' law. The lively motion within the steel bath probably affects the separation to a large extent. In spite of the rapid separation it could be shown that the number of the inclusions decreases with increasing casting temperature. It may be, however, that this occurrence is related to the circulation within the bath, being slower in a colder steel. The separation of inclusions which are the products of the deoxidation process takes more time than that of the above artificial inclusions. The latter tests furthermore indicate that the velocity of the chemical reactions of deoxidation must be considered to arrive at correct conclusions. 3 references. GN (12a)

Addition of Sand to Thomas Slag. (Ueber den Sandzusatz zur Thomasschlacke.) Edgar Spetzler & Albrecht Harr. *Stahl und Eisen,* Vol. 52, Apr. 21, 1932, pages 389-392.

Report 227 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion. Following data represents Thomas slag analysis with and without addition of dry sand:

	Sand added	Total P_2O_5	% P_2O_5 soluble in citric acid	% Slag soluble in citric acid	% Fines in Slag	SiO_2	Factor $\frac{SiO_2}{P_2O_5}$	% Si in Pig Iron
Ordinary practice	Yes	16-18	15-16	90-92	78-80	8.0	0.45-0.5	...
Test 1	No	16.4	15.4	93.9	79.7	6.4	0.39	0.35
Test 2	No	16.6	15.0	90.8	78.4	6.1	0.37	0.31
Test 3	No	17.7	14.8	83.4	77.1	6.9	0.39	0.36
Test 4	Yes	17.0	15.6	91.8	75.1	9.1	0.536	0.36

Solidification of Thomas slag takes place in so many ways that solubility of P_2O_5 could not possibly be regularly uniform. P_2O_5 solubility is not dependent on definite $\frac{SiO_2}{P_2O_5}$ factors. Addition of sand to converter results in higher ferromanganese consumption to produce deoxidation. Average of 363 melts when sand was added required 11.5% more Mn than melts without sand. Sand also interferes with desulphurization as shown by average of 20 melts. 51% of total S was removed without, and only 37% with sand. Sand also increases amount of time spent in repairing and making new tap hole plugs. Time saving of 32% is made without sand addition. Apparently sand addition gives poor overall operation. DTR (12a)

Modern Converter Practice. W. R. Cooper. *Foundry Trade Journal,* Vol. 46, Apr. 7, 1932, pages 219-220.

Discusses at considerable length the value of the Tropenas converter in the production of steel castings and the methods employed in controlling heats. Particular attention is given to the control of S in steel. OWE (12a)

The Production of Basic Open-Hearth Steel in United States by the Duplex Method using Talbot Furnaces. (Die Erzeugung basischen Siemens-Martin-Stahles nach dem Duplexverfahren in Verbindung mit Talbot-Oefen in den Vereinigten Staaten von Nordamerika.) E. Goebel. *Stahl und Eisen,* Vol. 52, Apr. 7, 1932, pages 340-344.

Summary of American production methods for basic open-hearth steel. Production of this class of steel by duplex method is carried out in acid converters with basic open-hearth tilting furnaces. Duplex method is subdivided into the lime method and limestone method. In the former method calcined lime is used as flux, while in latter unburned limestone is used. Limestone method is superior, producing steel of slightly better physical properties. Up to present time no definite comparison of physical properties relating to strength has been evolved for steel produced by duplex method and steel produced by pure basic open-hearth method. However, tests are under way on this matter. From American practice the duplex method in producing commercial brands of steels has been found cheaper than the scrap pig-iron method. Tonnage of an open-hearth plant may be varied within wide limits if the possibility exists of applying duplex method. Complete operating data using duplex method are given. DTR (12a)

Duplex Operation: Cupola-Electric Furnace. (Marche duplex: cubilot-four électrique.) Albert Kayl. *Journal du Four Electrique,* Vol. 41, Apr. 1932, pages 130-132.

Many years practice showed that for speeding production about 25%, reducing the cost and preparation of a better steel for casting the use of the molten Fe from the cupola is advantageous in making electric furnace heats. Usually 73% scrap and 27% molten Fe were charged in a 4 ton furnace. A detailed description of the operation and costs is given. JDG (12a)

Modern Trend in Steel-Making Practice. Josiah W. Jones. *Iron & Steel Industry & British Foundryman,* Vol. 5, Nov. 1931, pages 45-49.

Developments in the Bessemer process are few and of little importance. The trend in the open-hearth practice is to explore the physical, chemical and mechanical operations with the view to determine the quantities and the time factors involved. CHL (12a)

The Draw in Small Castings. (Les Tassements dans les Petites Pièces.) L. Gasquard. *Revue Fonderie Moderne*, Vol. 26, Apr. 10, 1932, pages 113-116.

1 The draw or sinking of a casting is a defect which occurs during the solidification of the metal and is characterized by a deflection towards the upper part of the cast piece. It is usually explained that the poured metal in its contact with the walls of the mold cools suddenly by closely taking the shape of the mold; the solidification of the rest of the system takes place gradually in the remainder of the liquid. If an element is present which interferes with the law of cooling the solidification of the liquid which is still in the interior of the already solidified parts due to the contact with the walls can only take place by causing a draw or sinking. 2 reasons in particular cause this phenomenon: the chemical sulphurization occurring during melting and the sulphurization produced at the moment of pouring into the mold due to the materials employed. In order to avoid this defect which is more prevalent in small than in large castings it is advisable to use a great percentage of new pig iron, not to employ mottled iron or white iron, to use an excess of limestone or lime and fluorspar, hard coke of less than 1% S, to use scrap only judiciously and removing from it pieces of steel and pieces too strongly oxidized, to calculate the charge carefully with respect to contents of Si and Mn, to deoxidize the melt properly with Al or Ti-thermite and to add the Mn with the ladle in the form of powder which promotes the separation of S as MnS. The draw is usually a rough cavity and in taking off the crust in machining a metal of heterogeneous grain and of slight resistance is found. Micrographs, chemical analyses and testing methods for S are given. Ha (12b)

Properties of Steel Ingots as Affected by Conditions of Preparation.—The Harmet Method. (Untersuchungen über die Eigenschaften von Stahlblöcken in Abhängigkeit von den Herstellungsbedingungen unter besonderer Berücksichtigung des Harmet—Verfahrens.) Walter Eicholz & Johannes Mehovar. *Archiv für das Eisenhüttenwesen*, Vol. 5, Mar. 1932, pages 449-469.

2 Report 222 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion, 20 illustrations, 6 tables of data, and 38 references. (1) An explanation is given for the formation of visual cracks and of behavior on solidification of steel, mechanically still in motion. Effect of conditions of operation on cracks is pointed out. (2) In agreement with Klinger's work, solubility of CO in steel in any appreciable amount under ordinary casting conditions is viewed as improbable, and the explanation for the many phenomena in the formation of external cracks or blow-holes may be given by the reversible reaction $FeO + C \rightleftharpoons Fe + CO$. (3) Herzog's opinions from his research work were practically confirmed; formation of visual cracks and blow-holes during solidification is to be attributed to the mechanical action of steel movement during solidification. (4) Characteristic properties of almost motionless steel, as well as distinction between continuous casting and single casting on the side were studied. (5) After a summary of most important factors in formation of primary structure of motionless steel, comparisons were made between ordinary ingots and those prepared by the Harmet method. (6) Completely sound ingots can always be made with certainty by the Harmet method, confirming Kriz's work, even with alloyed steel. The real advantage of the Harmet method consists in positive avoidance of axial cracks together with the finer cast structure in center of ingot and lack of strong liquation. (7) The large latitude of possibilities for primary cast structure by Harmet's method and its extensive adaptability to the properties of various classes of steel were demonstrated. (8) Chemical and physical action of mold wash with definite ingot sizes are given. (9) Properties of concave castings for manufacture of seamless tubes of large diameter and limited wall strength are described. DTR (12b)

The Separation of Graphite in the Crystallization of Cast Iron. S. S. Steinberg & K. A. Malyshev. *Metallurg* (Russia), Vol. 6, 1931, pages 123-129.

3 The separation of the graphite was investigated in relation to the raw material (white or gray iron), the superheating of the Fe, the duration of such heating, and the velocity of cooling. Graphite separates from liquid cast Fe in 3 forms: (1) in the form of a graphite eutectic consisting of very fine graphite laminae (0.01 mm.), (2) in larger leaves (0.1 mm.), and (3) in the form of large aggregations and nests. Super-heating the Fe to 1600° C. and keeping it in the liquid condition a long time decreases the amount of graphite separating and favors the formation of the fine graphite eutectic. Slow cooling during the period of crystallization increases the amount of graphite separating and favors the formation of the coarser formations. After remelting the gray metal yields more graphite than the white. (12b)

Calculation and Measurement of the Volume of a Pipe. (Berechnung und Messung des Lunkervolumens.) P. Kroll. *Revue Technique Luxembourgeoise*, Vol. 24, Jan.-Feb. 1932, pages 18-19.

4 3 simple formulas are developed by means of the specific volume-temperature diagram showing the 3 physical states of the metal, that is, solid, doughy and liquid, which permit the exact study of the volume of each pipe formed in an ingot in order that conditions may be altered so that the pipes become a minimum. Ha (12b)

Progress in the Construction of Die-Casting Machines. (Fortschritte im Spritzguss-Maschinenbau.) A. Kaufmann. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 76, Jan. 30, 1932, pages 105-107.

6 The development of the last 5 years in machines for die-casting of Al, Zn and brass are discussed. A few details of such machines are given. Ha (12b)

Design of Die Casting Machinery. Correspondence from Sam Tour. *Metal Progress*, Vol. 21, Apr. 1932, page 75.

Comments on Ernst Seidewitz' article dealing with die casting machinery in the January *Mechanical Engineering*. Tour points out that the danger from squirting molten metal increases when parting lines of die are horizontal. WLC (12b)

Modern Casting Cars for Bessemer Steel Plants. (Neuzeitliche Giesswagen für Thomas-Stahlwerke.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Apr. 3, 1932, pages 134-137.

This is an illustrated description of steel casting cars as they have been built and improved in recent years by the Demag Company, Duisburg, Germany. GN (12b)

Normal and Inverse Ingot Segregation of Aluminum-Copper Alloys as dependent on the Velocity of Solidification. (Die normale und umgekehrte Blockseigerung von Aluminium-Kupferlegierungen in Abhängigkeit von der Erstarrungsgeschwindigkeit.) H. Bohner. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 4, Jan.-Feb. 1932, pages 24-30.

The influence of different, exactly defined cooling velocities on the segregation of Cu in Al-Cu alloys in round bars is investigated. The tests lead to the conclusion that the normal and the inverse segregation respectively is a function of the freezing velocity. It can be demonstrated that with increasing cooling velocity at first a normal, gradually increasing segregation takes place which changes after exceeding a definite velocity of heat conduction into the inverse segregation where with increasing cooling velocity the differences in the Cu content between edge and core of the bar become smaller. The differences in Cu-content between edge and core are reduced at both inverse and normal segregation by diffusion phenomena which are independent of temperature and duration. The Cu content of the edge zone is further influenced at the end of the solidification by the squeezing out of the remaining melt to the ingot surface. 13 references. Ha (12b)

Eliminating the Shell Defect in Ingot Molds. D. J. Thomas. *Iron & Steel Industry & British Foundryman*, Vol. 5, Mar. 1932, pages 231-232.

Shell defect is a very thin layer of Fe in the form of a light scab often extending the entire length of the mold and situated always in the 4 angles of radii. It is caused by segregation of phosphide eutectic. Equalizing solidification through design of core bar eliminates this difficulty. See also *Metals & Alloys*, Vol. 2, Dec. 1931, page 319. CHL (12b)

Experiments on Segregation in Steel. J. H. Andrew & D. D. Howat. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 608-612, 613-620.

Experiments have been carried out on small ingots of steel containing an excess of impurities. It is shown that the impurities tend to float upwards into the head of the ingot if the steel is kept quiescent for a prolonged time in the molten state. When the ingot is stirred immediately previous to solidification, no segregation is produced, showing that differential solidification does not play the part usually assumed in the phenomenon of segregation. So-called soluble impurities such as P and C appear to form a complex with S, this complex being insoluble in liquid steel. From these data the theory that segregation in steel ingots is due to differential solidification is discussed, and shown to be untenable. Evidence is given to show that the concentrated areas of impurities usually found in steel ingots are caused by the floating upwards of impurities while the steel is liquid. The theory of segregation advanced is that both liquid and solid inclusions which are insoluble in steel tend to rise to the surface of the ingot, due entirely to their low sp. gr. as compared with steel. WAT (12b)

Volume Changes of Cast Irons During Casting. E. J. Ash & C. M. Saeger, Jr. *Bureau of Standards Journal of Research*, Vol. 8, May 1932, pages 601-614.

The volume changes occurring in 8 types of cast Fe during cooling from the liquid state to room temperature are given. The irons varied in composition from gray Fe to white Fe. The coefficient of volume shrinkage in the liquid state for irons over the range of temperature studied was 0.011% per ° C. The volume change during solidification varied from an expansion of 1.65% in a gray Fe to a contraction of 5.85% in a low-C low-Si type of Fe. The linear contraction of the sand cast bars varied inversely with the Si and C content and also with the cross-sectional area. The lowest linear shrinkage value measured was 0.67% (1½" sq. bar) and the highest was 2.08% (¾" sq. bar). In both heating and cooling curves and in the sand-cast condition bars, a pronounced effect was observed at about 1070° C. possibly indicative of some transformation. An expansion was observed at this temperature during the freezing of all melts of cast Fe. This expansion, however, was not due to decomposition of cementite alone, for white Fe bars having no free graphite present showed this same phenomenon. This expansion may have been caused by the separation of dissolved gases during solidification as has been pointed out by previous investigators. See also *Metals & Alloys*, Vol. 3, May 1932, page MA 136. WAT (12b)

Centrifugally Cast Guns. (Nach dem Schleudergussverfahren hergestellte Geschützrohre.) *Die Röhrenindustrie*, Vol. 21, July 18, 1931, pages 173-174.

Reports on experiments carried out in the Watertown Arsenal with 0.35-0.38 C, 0.6-0.7 Mn, 0.3 Mo, 0.05 V steel which was used for the centrifugal casting of 75 and 150 mm. guns respectively. The casting process with emphasis on the precautions to be borne in mind is fully outlined and the advantages and deficiencies of this kind of manufacturing method are critically discussed. EF (12b)

Variations in Chemical Analyses of Steel Ingots. K. R. Binks. *Iron & Steel Industry & British Foundryman*, Vol. 5, Nov. 1931, pages 55-56.

2 types of segregations are noticeable in steel ingots, one in which the enriched portions of the last liquid to solidify are brought into the head or discard of the ingot, the other, occurring in the body of the ingot where the concentrations of the individual constituents may be greater or less than the mean. Rapid cooling retains the constituents *in situ* and the localized differences become small. Segregation is further influenced by mold design, speed of teeming and temperature of casting. CHL (12b)

Forging (12d)

Construction of Dies. G. A. SMART. *Heat Treating & Forging,* Vol. 18, Feb. 1932, pages 111-112.

Deals with dies for board hammers and steam-hammers. MS (12d)

Pressing of Magnesium Alloys. R. BARBANEL. *Light Metals,* Feb. 1932, pages 40-47. (In Russian).

Mg alloy corresponding to Dow F type (4.0 Al, 0.3 Mn) was studied in regard to casting and pressing into tubes. Much improvement could be obtained in casting by separating the crucible in 2 compartments by a steel slide and keeping the larger compartment covered with liquid slag while the metal was poured from the smaller one with which it was connected at the bottom of the crucible. The best temperature for pressing was found to be 350°-370° C. Higher temperatures caused checking while lower required excessive pressure. (12d)

Makers of Forgings Effect Economies in Production. *Steel,* Vol. 90, Jan. 4, 1932, page 159.

Notable developments in the forging industry during 1931 include a new pressure method of forging to closer limits, an increase in the number of rotary-hearth furnaces, better temperature control, improvements in forging machinery leading to higher precision, and the wider use of higher speeds, automatic lubrication and mechanical handling in foundries. JN (12d)

New Application Possibilities of Hot Pressing Methods. (Neue Anwendungsmöglichkeiten des Warmpressverfahrens.) K. SPRINGORUM. *Deutsche Motorzeitschrift,* Vol. 9, Jan. 1932, pages 20-22.

Instead of cast Ni-alloys and hot pressed brass which is later Ni or Cr plated, the writer urges the use of the special Ni alloy Admiro (Admos, Allgemeine deutsche Metallwerke, Berlin) which is intended for hot pressing methods. The alloy is silver-white, corrosion resistant and takes a bright luster on polishing. The tensile strength is 60 kg./mm.^{2} and the elongation is 15%. Difficulties in making fittings, door knobs, window handles, etc., are overcome by drop forging over a steel core. The alloy is in use on several German liners. EF (12d)

Manufacture of Forged Shafts. R. V. WALLACE. *Heat Treating & Forging,* Vol. 18, Feb. 1932, pages 95-97, 101.

In forging shafts, operator should insure against overheating or burning, preparatory to forging; work well in the plastic range to avoid the crystalline distortion and strain attendant on working at too low a temperature; and finish the metal at the critical range to obtain the maximum grain refinement possible. As close control over these and other important metallurgical elements is rather difficult, finished forging will generally require a special heat treatment in order to be made more dependable for service. This treatment consists of a preliminary normalizing at high temperature, about 300° F. above the critical range, followed by a second normalizing at normal temperatures. MS (12d)

Special Tool Steels for the Working of Non-Ferrous Metals. (Sonderstähle in Werkzeugen zur Verformung von Nichteisenmetallen.) V. FABIAN. *Zeitschrift für Metallkunde,* Vol. 24, Feb. 1932, pages 40-42.

Materials for dies; behavior of alloy steels in deforming cold and hot metals; reasons for poor performance; hair-cracks and tension-cracks; influence of correct heat-treatment upon performance by elimination of hair and tension-cracks. RFM (12d)

Machining by Pressure. JOHN H. FRIEDMAN. *S. A. E. Journal,* Vol. 30, Feb. 1932, pages 80-83.

A new type of forging press is described which works more accurately than the known machines. Finish forging on this machine can be done on the heat remaining from forging or annealing at a temperature below that at which scale is formed. Also cold coining can be done with it. The economy of this method is great as it eliminates roughing cuts, reduces the number of handlings and, in some cases, also any further machining. The machine is also used for straightening and sizing malleable castings and for hot-forging both ferrous and non-ferrous metals. A number of forged parts are illustrated. Ha (12d)

Compressed Air Reduces Forge Hammer Cost. F. A. KOLB & R. C. GRIMSTEAD. (Duquesne Light Co.) *Heat Treating & Forging,* Vol. 18, Mar. 1932, pages 171-173.

Woodings-Verona Tool Works, Verona, Pa. has two 4600 lb. and one 1500 lb. drop hammers and two 2000 lb. and two 1000 lb. forging hammers. These were formerly operated by steam supplied by two 300 hp. stoker-fired boilers. About a year ago steam was replaced by compressed air supplied at 100 lb. from a 2-stage 18" x 11" x 14" compressor driven by a 350 hp., 100% power factor, 3-phase, 2200 volt, 60 cycle synchronous motor. Compressor feeds directly into an air receiver 5 ft. in diameter and 12 ft. long. To adapt the hammers for air operation, the lap of the piston-valves was increased 1/16" on each end of the piston to prevent idling of the ram between operations, and the hammers were repacked. Experience with air operation shows that cost of operation has been reduced about 50%, dripping of hot water on the dies has been eliminated, packing expense has been reduced, and idling of the ram between operations has been eliminated. Describes method of analyzing savings to be expected by replacing steam with air, before the installation was made. MS (12d)

Shearing & Punching (12e)

New Type Shears with Speed Control. (Neue Fliegende Schere mit Geschwindigkeitsregelung.) HEINRICH FLENDER. *Stahl und Eisen,* Vol. 52, Apr. 14, 1932, pages 371-372.

Diagrams showing speed-regulated shears as developed by Klein Bros. Machinery Co., Dahlbruch, are illustrative. Used for cutting hot billets up to 40x40 mm. and for rolling mill speeds from 2 to 4 m./sec. Operated by steam or compressed air. Change from one speed to another is made by changing time for end of exhaust and takes 1 min. for a rolling speed of 3.5 m./sec. Total time for one cutting stroke and one return stroke, 0.56 sec. Additional shears are manufactured for cutting other sizes of billets, mill bars, or rods. DTR (12e)

Extruding (12f)

The Extrusion of Metals. C. A. COLOMBEL. *Rolling Mill Journal,* Vol. 5, May 1931, pages 355-358; June 1931, pages 419-422, 430-431.

Introductory article. The author describes 3 early experiments presented to the Imperial Institute of France by H. Tresca in 1864 on the flow of metals under pressure. These experiments tend to show: (1) that a lateral flow of metal occurs during extrusion together with an enveloping of the upper parts of the slug by thin envelopes of metal originating from the lower parts; (2) that the flow of metal from axis to circumference is greatest at the middle and least at the upper and lower surfaces of the extruded slug; and (3) that metals flow through orifices under pressure in the form of hollow jets, thereby resembling the flow of liquids. The second article continues with a description of early experiments and furnishes a discussion of the flow of metals through circular, triangular and quadrangular orifices, through 2 circular orifices simultaneously, and through lateral orifices of circular and square cross-sections. JN (12f)

Power Demand and the Flow Procedure in Extrusion Presses. (Kraftbedarf und Fliessvorgänge beim Stangenpressen.) *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 79-84.

A description of laboratory studies upon the cold extrusion of Sn and Pb, in which the flow of metal is followed by the displacement of reference lines in the original piece; including plant studies of the hot extrusion of brass (58% Cu, 2% Pb) in a 1000-ton press. The influence of piece length, die length, extrusion velocity, extrusion degree (ratio of cross-sectional area of original piece to that of extruded piece), and die form upon the processes of flow and the power demands has been studied. The structure and properties of extruded brass are described and illustrated. Concluded with a discussion of theoretical equations of flow. RFM (12f)

The Structural Changes during the Commercial Shaping Processes. (Die Formänderungen bei technischen Formgebungsverfahren.) E. SIEBEL. *Die Naturwissenschaften,* Vol. 19, June 5, 1931, pages 515-518.

The difficulties of numerically evaluating deformation processes are pointed out. Distortions are traced with respect to (a) deformations in a body consisting of planes perpendicular to each other and (b) to stretching plus an additional displacement. Drawing tests with soft annealed Cu-rods through various dies were performed. A coördinate system scratched onto the surface, disclosed a uniform stretching over the entire cross-section and additional distortions towards the edge. Extruded Pb showed the same phenomena, whereas cold-rolled material did not exhibit any distortions of the cross-section. The second part of the paper pertains to the courses of deformations in the deformed regions. The appearance of flow lines starts an appreciable distance from the die and comes to an end in the die itself. In the extrusion press an upsetting effect takes place at the outer parts of the extruded body. The flow lines on drawing, extruding and punching are shown in the illustrations. EF (12f)

Machining (12g)

New Method of Drilling Motor Cylinders. (Ein neuer Weg zur Bearbeitung von Zylinderbohrungen.) H. IBY. *Deutsche Motorzeitschrift,* Vol. 9, Jan. 1932, pages 16-18.

6 main requirements to be met, when making cylinders in motor blocks are summed up. The new "fine drilling method," which employs Widia (tungsten carbide metals) or diamonds, is characterized by high cutting speeds and small feeds. The usual drilling and finishing methods are critically discussed and the defects at the cylinder walls are shown in various micro-photographs made during an investigation in the Technische Hochschule Wien. A comparison was made with the new method, which worked cleaner, the higher the cutting speed and the lower the feed. EF (12g)

The Machinability of Steel in Dependence on the Heat Treatment as Tested by The Drilling Method According To Keep-Lorenz. (Beitrag zur Frage der Bearbeitbarkeit des schmiedbaren Eisens in Abhängigkeit von seiner Wärmebehandlung unter Verwendung des Bohrverfahrens nach Keep-Lorenz.) G. GUTBERLET. Doctor's thesis, Technische Hochschule Dresden, 61 pages. Publisher: Formmhold & Wendler, Leipzig, 1931.

The machinability of 5 different steels was tested by the Keep drilling test. The structure of these steels had been varied (1) by annealing at increasing temperatures, (2) by hardening and tempering at increasing temperatures, (3) by spherodizing the Pearlite. After each of the above heat treatments the following properties were tested: Brinell hardness, tensile strength, yield point, elongation, reduction of area, notch toughness, grain size, machinability and resistance to machinability. The machinability was tested by the Keep method which takes the depth of drilling after 100 revolutions as indicative of the machinability. The resistance to machinability was determined by measuring the turning moment transmitted from the drill to the piece to be drilled. GN (12g)

Diamond and Widia. (Diamant und Widia.) F. K. BÖCK. *Maschinenkonstrukteur-Betriebstechnik,* Vol. 64, Nov. 10, 1931, pages 220-223.

A comparative study was made on the structure, properties, working loads, and price of Widia and diamond-tipped tools. MAB (12g)

Cutting Fluids and Their Applications. J. D. RONEY & G. L. SUMMER. *American Machinist,* Vol. 76, Jan. 14, 1932, pages 50-53, 67.

When a single machine performs severel operations it is best to use a cutting fluid suitable for the most severe operation and not change fluids. Discusses water cutting fluids and lard oil combinations. The real information in the article is condensed in table form showing the cutting fluid used for various machinery operations on the cold rolled steel, axle steel, tool steel annealed, heat-treated bronze rod, cast bronze, cast steel, wrought iron, sheet iron, fiber, hard rubber, and micarta. RHP (12g)

Machinability of Cast Iron (Die Zerspanbarkeit des Gusseisens im Drehvorgang.) A. Wallichs & H. Dabringhaus. *Stahl und Eisen,* Vol. 51, Oct. 1, 1931, pages 1233-1234.

In order to test the machinability of cast iron turning experiments were carried out on 21 different types of cast iron. High speed steel tools were used and the turning speed was determined which was necessary to ruin the tool after a turning time of 60 minutes. Such "cutting time-speed" curves were established for all cast irons tested, and for various depths of cut. The results show that in doubling the feed there results double the decrease of the cutting speed as doubling of the depth of cut brings about. The results of the cutting tests were also plotted against the hardness of the cast irons used and it is shown that there is no linear dependence between machinability and hardness as is generally assumed. But a rather smooth curve can be drawn through the points marking the results. Though the fluctuations of the individual points are larger than in establishing the same relation for steel (A. Wallichs & H. Dabringhaus, *Maschinenbau,* Vol. 9, 1930, pages 257-262) it can be stated that the machinability of non-alloy cast iron is at least approximately related to its hardness. In plotting the results for various angles of the tool, speed, feed, depth of cut, hardness of the material to be machined, etc. in so-called "Nomograms" the best conditions of machining cast iron can easily be determined. GN (12g)

Ramet. L. Anastasiadis. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, page 66.

Effect of Alumina on the Machining of Steel: Its Determination. (Influence de l'Alumine sur l'Usinage de l'Acier: Son Dosage.) R. Collee. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 455-457.

Difficulties encountered in boring steel because the tools dulled were found to be due to the pressure of Al_2O_3 in the steel, which is very hard. The method used for determining alumina in steel consists in dissolving the sample in strong mineral acids, fusing the insoluble residue with Na_2CO_3, taking up in HCl, filtering off SiO_2 and precipitating the Al_2O_3 in AcOH solution as phosphate after reducing any Fe present by means of $Na_2S_2O_3$. Describes the mechanics of machining and its testing. MAB (12g)

How to Make Carbide Tools Pay. J. M. Highducheck. *American Machinist,* Vol. 76, Jan. 7, 1932, pages 16-19.

Reviews methods of using tungsten carbide tools for grinding. Presents methods of keeping records of work done. RHP (12g)

Researches on the Cutting Force. II. Cutting Action of Planing Tool. Makato Okoshi. *Scientific Papers Institute Physical & Chemical Research,* Tokyo, Vol. 14, Oct. 20, 1930, pages 193-225. In English.

The cutting action of a simple planing tool was examined microscopically at different cutting speeds and depths of cut. The tools used had straight cutting edges, clearance and side rake angles of 5° and 0° respectively, and varying top rake angles. Preliminary tests with wax indicated that below a critical cutting speed the cut is of the crack type, and above this speed of the slip type. The critical cutting speed increases with the depth of cut, the rate of this increase being greater as the cutting angle decreases from 90°. With cast Fe, mild steel, and Al the same principles hold, and it is considered that the "flow type" of cutting described by Rosenhain and Sturney (*Engineering,* Jan. 30 and Feb. 6, 1925) is merely a variety of the slip type. With 60:40 brass, and Cu, the cutting action is always of the slip type, and no critical speed is observed. The change from one type to another is attributed to change of frictional resistance between the chip and top rake surface. In the case of brass the friction is very low. This is shown to result in the material being pulled upwards during the cut instead of being compressed downwards. This produces the "chattering" of the tool often met with in cutting brass. The direction of slip is shown to change with the cutting angle and material, in contradiction to the conclusion of Rosenhain (loc. cit.), J. T. Nicolson (*Engineer,* Apr. 14, 1902), Stanton (*Engineering,* Jan. 30, 1925), and Hankins (*Proceedings Institution Mechanical Engineers,* 1923), while Herrmann's equation (*Ingenieur und Maschinenmechanik,* Vol. 3, III, Abt. 1, page 825) does not agree with the present results. Ha (12g)

Drawing & Stamping (12h)

The Stresses in Wire Drawing. E. M. Horsburgh. *Transactions Institute Engineers & Shipbuilders, Scotland,* Vol. 74, 1931, pages 318-354.

In the discussion of this paper many interesting points were raised, including the properties of metal suitable for wire drawing; the properties which wire must possess in addition to tensile strength, such as flexibility, durability, and recuperability; and the influence of annealing and heat-treatment on the strength and hardness during drawing. There was also considerable discussion on the stresses occurring in the wire, the pressures exerted by the die, and on stress analysis as applied to elastic material, plastic material, and viscous fluids. The author attempts to find analytically the variation and distribution of the stresses in the die itself along its axial length during drawing. Ha (12h)

Experiments in Wire-Drawing; Behavior of a Composite Rod. W. E. Alkins & W. Cartwright. *Engineering,* Vol. 132, Sept. 25, 1931, pages 397, 423-424.

Includes discussion. Condensed from paper read before the Institute of Metals, Sept. 15, 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 272. LFM (12h)

The Drawing of Non-Ferrous Wires. E. L. Francis & F. C. Thompson. *Engineering,* Vol. 132, Nov. 13, 1931, pages 622-625.

Condensed from paper read before the Institute of Metals, Zurich, Sept. 15, 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 314. LFM (12h)

Vital Variables in Steel Stampings. *Product Engineering,* Vol. 3, Apr. 1932, pages 141-144.

The economical production of pressed metal goods depends to a great extent on proper correlation of design, selection of material and manufacturing methods. This is illustrated by examples of electrical apparatus. Ha (12h)

Studies of the Wire-Drawing Process. II. Factors Involved in the Power Requirements. F. C. Thompson & E. L. Francis. *Carnegie Scholarship Memoirs, Iron & Steel Institute,* Vol. 20, 1931, pages 87-124.

11 references. The several factors of mechanical properties, speed of drawing, dimensions of the wire, percentage reduction, angle and contour of the die, temperature, coefficient of friction, and space-lattice of the metal are involved. These are discussed theoretically and mathematical relations deduced. The power required is proportional to tensile strength, rate of drawing, and final cross-section as dimensional factors times a function of the reduction without dimensions which will contain the elements of the other factors above mentioned. Material used in the experimental work varied in tensile strength from 2840 lbs./in.^{2} for Al to 38,800 lbs./in.^{2} for cold drawn Ni and all material except a mild steel of 25,600 lbs./in.^{2} tensile were of face-centered cubic lattice. The effect of low and high speed of drawing were made in connection with the study of the mechanical properties and speed of drawing in their influence on the power requirement. The power requirement is shown to be a linear function of the elastic limit in tension for the several non-ferrous materials. The mild steel falls well away from the curve showing the stresses required are materially altered with the lattice of the material. At very low rates the speed is somewhat affected but at higher speeds the rate of drawing can be increased over a wide range without affecting the tension required. The tension is shown to be closely proportional to the percentage reduction. The experimental results confirm the theoretical equation of the preface. WLC (12h)

Pickling (12i)

The Muriatic Acid Dip for Metal Ware Galvanizing. Wallace G. Imhoff. *American Metal Market,* Vol. 38, No. 178, Sept. 12, 1931, pages 5, 7, 9.

Muriatic acid dip in metal ware galvanizing is used to remove the corrosion between pickling and galvanizing operations, and also to counteract oxidizing effect that the H_2SO_4 pickle has on the work. This dip may be considered as a balance to counteract or overcome action of the pickle. Under practical conditions the stronger the H_2SO_4 solution and the higher the pickling temperature, the stronger the HCl dip must be to counteract it. Many kinds of Fe oxides and scales formed during the finishing process and also in the corrosion of steel surfaces later on. The writer gives examples of 15 different plants with their methods of pickling and dipping, strength of all reagents with details of all metal-ware pickling operations. Cites the acid and Fe content of HCl dip when good quality product is being produced:

	Acid content	Iron content
1.	11.30%	6.00%
2.	6.00%	5.00%
3.	5.50%	2.50%
4.	6.00%	4.50%
5.	7.50%	4.00%

Modernized Pickling Room Proves Investment. *Iron Age,* Vol. 128, Dec. 10, 1931, pages 1484-1486.

Description of the pickling room equipment of the Russell, Burdsall & Ward Bolt & Nut Co., Port Chester, N. Y., for cleaning wire rods. The most noteworthy improvements are the tanks and their automatic control. VSP (12i)

Pickling for Plating. Clayton M. Hoff. *Brass World,* Vol. 27, June 1931, pages 129-131.

The purpose and chemistry of pickling for the preparation of Fe and steel sheets for plating, the acids used and characteristics of each, new developments and means of preventing acid brittleness are discussed. See *Metals & Alloys,* Vol. 3, May 1932, page MA 138. Ha (12i)

The Pickling of Iron and Its Alloys. *American Machinist,* Vol. 75, Dec. 10, 1931, pages 905-906.

Summarized review of pickling practice. Caustic soda or other cleaning treatment should be used before pickling to remove oil and grease. H_2SO_4 may be used in concentration of 2-15%. HCl from 10-50% has more rapid action but is expensive. The acid strength and temperature, pitting, acid brittleness, sheet blistering, inhibitors and the formation of iron salts are discussed. RHP (12i)

Cold Working (12j)

Influence of Cold Work upon Plasticity at High Temperatures. (Einfluss von Kaltreckung auf die Plastizität bei erhöhten Temperaturen.) E. Schmid & I. Wassermann. *Zeitschrift für Metallkunde*, Vol. 23, Aug. 1931, pages 242-243.

1 The plasticity of hard-drawn and annealed Cu wires (0.15 mm. diameter) was studied by taking curves of elongation under constant load as a function of time at temperatures between 200° and 450° C. Between 250° and 400° C. the hard-drawn wire elongated more rapidly than the annealed wire, presumably because of the greater lattice mobility accompanying the phenomena of crystalline recovery and recrystallization. At 450° C. the rate of flow in the 2 wires was found nearly equal, owing to the rapid recrystallization of the cold-drawn wire. At 200° C. the rate of flow of the cold-drawn wire was somewhat slower. RFM (12j)

Calculation of Internal Stresses in Cold-Drawn Tubes. (Berechnung der Restspannungen in kaltgezogenen Rohren.) N. Dawidenkow. *Zeitschrift für Metallkunde*, Vol. 24, Feb. 1932, pages 25-29.

2 Previously proposed methods for the quantitative determination of internal stresses are critically reviewed, and a new mathematical development of the necessary formulae is given. An experimental analysis of the stresses in a cold-drawn brass tube is made by the use of the formulae developed. RFM (12j)

Influence of Cold-Work on the Specific Heat. (Der Einfluss der Kaltbearbeitung auf die spezifische Wärme.) J. A. M. van Liempt. *Die Naturwissenschaften*, Vol. 19, Aug. 14, 1931, page 705.

Further Experiments on the Magnetostriction of Cold Drawn Wire. J. S. Rankin. *Journal Royal Technical College* (Glasgow), Vol. 2, Jan. 1932, pages 587-589.

4 In a previous paper (above Journal, Vol. 2, 1931, page 385) it was shown that the magnetostriction of 7/32" diameter rod is decidedly different from that of the same iron reduced by cold-drawing to 1/16" diameter. Whereas the 1/16" cold drawn wire shows only a small expansion up to a field of about 40 c.g.s. units and thereafter for higher fields a contraction, the 7/32" material exhibits much bigger expansion and no contraction even at a field of about 160 c.g.s. units, the highest used. Tests were also carried out on ⅛" diameter wire supposed to have been cold drawn from the 7/32" diameter rod, but instead of obtaining a magnetostriction curve intermediate between the other two it was found that cold drawing from 7/32" diameter had increased the magnetostrictive expansion. It was, therefore, considered desirable to check this rather astonishing result, and the present research records results indicating conclusively the effect of successive draws on magnetostriction. Briefly, as the diameter is reduced in the successive stages of the drawing operation the effect on the magnetostriction is a continuous decrease. WAT (12j)

Cleaning (12k)

Degreasing and Cleaning of Metal Parts. (Die Entfettung und Reinigung von Metallteilen.) A. Burg. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Apr. 3, 1932, pages 147-148.

The efficiency of the various chemical reagents used for degreasing and cleaning of metals is discussed. GN (12k)

Rust Resistance for Enameled Sheet Steel. F. P. Spruance. *American Machinist*, Vol. 76, Jan. 14, 1932, pages 48-49.

6 An abstract of an unpublished paper presented at the Society of Automotive Engineers, Production meeting, Detroit, Oct. 7-8, 1931. Enameled fenders were rusting due to alkaline salts from the rinse water. A form of phosphoric acid called "Deoxylyte" was used to neutralize the alkali. This does not remove oil so "Deoxidine," a phosphoric acid containing oil solvents, is used. To produce a surface to which enamel primers will adhere a process known as the "Bonderite" process is used. This is a treatment with a mixture of manganese dihydrogen phosphate and a very small amount of copper phosphate. This is followed by washing with water and enameling. RHP (12k)

The Denickeling Bath. (Das Entnickelungsbad.) *Oberflächentechnik*, Vol. 9, Apr. 19, 1932, page 80.

Material which has developed defects in the Ni plating process is usually later put in a bath to take off the Ni again and to prepare the goods for another plating process. This denickeling bath requires a certain care if the denickeled parts are to be in such condition that they are ready, after slight repolishing, for the Ni bath. Particular attention must be paid that the denickeling bath does not become oversaturated with Ni salts. The noxious H_2SO_4 fumes which the bath develops can safely be overcome by covering the bath with "Chromprotect." Similar precautions and treatments are discussed for baths for taking off deposits of Cd, Cr, Cu and brass, and Zn. Ha (12k)

Manufacturing of Cleaning Barrels for Castings. (Die Selbstanfertigung von Gussputztrommeln.) G. Krebs. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Feb. 21, 1932, pages 77-79.

The article discusses the procedure to be followed in making barrels for cleaning castings. Some objections to the cleaning of castings in barrels are refuted. GN (12k)

Polishing & Grinding (12l)

The First Research Station for the Grinding and Polishing Industry. (Die erste wissenschaftliche Zentralstelle der Schleif- und Polierindustrie.) *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Jan. 24, 1932, pages 48-49.

An illustrated description is given of the permanent exhibit of the newly established "Institut für Schleif- und Poliertechnik" at the Technische Hochschule of Braunschweig. GN (12l)

Special Grinding Machine for Eccentric Discs. (Sonderschleifmaschine für Nocken.) Weil. *Die Werkzeugmaschine*, Vol. 36, Feb. 15, 1932, pages 40-41.

10 A new machine for grinding eccentric discs as they are used in automobile construction is described. The new machine is built by J. E. Reinecker, A. G. Chemnitz, Germany. GN (12l)

Hardening by Grinding. George J. Murdock. *American Machinist*, Vol. 76, Jan. 7, 1932, page 7.

It is often difficult to harden press tools without distorting them. Sometimes they may be hardened by grinding with a filled carborundum wheel. A mixture of beeswax and lard oil are applied to the carborundum wheel for filler. RHP (12l)

The Application of Corundum to Grinding Discs. (Die Verwendung von Korund zur Herstellung von Schleifscheiben.) J. Dorfner. *Berichte der deutschen keramischen Gesellschaft*, Vol. 13, Feb. 1932, pages 86-88.

A general survey is given on composition, properties and application of corundum. GN (12l)

Protecting Surface of Polished Stainless Steel Sheets During Forming. C. C. Snyder. *Sheet Metal Worker*, Vol. 23, Mar. 18, 1932, page 134.

In order to avoid scratching and otherwise marring the polished surface in working sheet steels the dies should be highly polished; a lubricant of lithopone and linseed oil is recommended or the use of thin paper between die and polished metal. A film of iron which often forms by the contact with steel rollers, steel dies or shears and discolors the surface, should be removed with HNO_3 passivation treatment or proper buffing compounds. Ha (12l)

Modern Roll Grinding. N. Leerberg. *Rolling Mill Journal*, Vol. 5, May 1931, pages 323-326, 349-350.

For the successful grinding of roll necks and roll bodies, the roll drive must be positive in action and free of vibration. The roll supports must run dead true and carry the weight without heating. The grinding wheel must run at a speed giving the least vibration, must not wear too fast or glaze rapidly and must wear evenly and run without chatter. The spindle must be absolutely rigid and the cambering attachment must be rigid, frictionless and adjustable to any curvature. Several examples of proper grinding practice are described. JN (12l)

The Abrasive Wheel and Its Applications. W. R. Gutteridge. *Transactions Junior Institution of Engineers*, Vol. 41, Part IV, Jan. 1931, pages 164-179.

Under the heading of grinding there are 2 main branches, precision grinding and offhand or stock removal, which are in turn subdivided into about 30 smaller groups, principally differentiated by the type of machine in use. A third branch, hand grinding, is not dealt with in the paper. In precision grinding the chief factors to be taken into account are the class of wheel to be used, the surface speeds of the work and of the wheel, and the traverse of the wheel and the work. Cylindrical, universal and surface grinding machines are considered. A few safety suggestions and devices are mentioned. WHB (12l)

Polishing vs. Plating Standards. Ernest Lamoureux. *Metal Industry*, N. Y., Vol. 30, Apr. 1932, pages 153-154.

The proper polishing of the base metal before plating is essential for production of durable electrodeposits. PRK (12l)

Steel Mill Roll Finishing. H. J. Wills. *Abrasive Industry*, Vol. 12, Dec. 1931, pages 16-17.

The stresses set up at the grinding face by the wheel rotation and work pressures are close to ultimate impact resistance of the bond and grain structure. A slight increase in pressure will break or distort the grains and a decrease will cause dulling of crystals and glazing. The relation of wheel speed to work speed will determine shearing force. As wheel speed is increased in ratio to work speed, the stresses set up between work and wheel face are lessened, and the wheel is not broken down as rapidly as under lower wheel speeds. The degree to which wheel action is affected depends on the characteristics of the abrasive wheel used. Wheel and work speeds should be adjusted to compensate for the variation in stresses due to the reduction of the wheel diameter. (1) Rigid, nonvibrating machine elements permit the use of softer wheels which result in an increase in production. (2) Large diameter rolls permit softer bonds owing to the greater area of contact between wheel and work. (3) For chilled iron rolls, silicon carbide wheels are used for rough grinding and finishing; for hardened steel rolls, alumina wheels are used. (4) Finishing cuts may be improved with narrow wheels. To avoid changing wheels it is practical to dress the wheel face to the desired width. Dressing for rough cuts is done most economically with the conventional dresser. For finishing cuts a diamond is necessary. WAT (12l)

Polishing Stainless Steel Sheets. C. C. Snyder. *Sheet Metal Worker*, Vol. 23, Feb. 19, 1932, pages 80-94.

8 The types of polishing and buffing wheels and polishing and buffing materials are specified for use on "Enduro" stainless steel. Ha (12l)

Accurate Surface-Grinding of Castings. *Machinery*, Vol. 38, Oct. 1931, pages 122-123.

Description of the methods of accurately grinding large flat surfaces by the use of vertical surface grinders built by the Blanchard Machine Co., Cambridge, Mass. RHP (12l)

The Churchill Rod-Grinding Machine. *Iron & Coal Trades Review*, Vol. 124, Mar. 25, 1932, page 524.

9 The machine is designed for the rapid grinding of long bars of circular cross section to very fine limits with a maximum capacity of 1½" in diameter. An exact description is given of all the motions; the machine is driven by a 25 H.P. motor. Ha (12l)

Polishing of Aluminum Ware in Quantity (Polieren von Aluminiummassenwaren). *Die Giesserei*, Vol. 19, Apr. 29, 1932, page 169.

The articles are put into a rotating drum in which steel balls with a polishing agent rotate with the wares. A good polishing composition is:

3 parts of quartz or pumice stone
2 parts of vaseline
½ part of montan wax
1 part of iron oxide
5 parts of Vienna polishing chalk.

To get good surfaces the articles must previously have been pickled in NaOH or in a special Al pickling fluid. Ha (12l)

Copper Industry in 1931—Advance Summary. H. M. Meyer. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 118, June 7, 1932, 5 pages.

Smelter output of Cu from domestic ores in 1931 (521,355 tons) decreased 25% from production in 1930 (48% in value), and refinery production from domestic and foreign sources (750,721 tons) declined 30%, the smallest outputs since 1922. Imports of unmanufactured Cu decreased 28% and exports of Cu 26%. Stocks of refined Cu increased 50%, and of blister Cu declined 23%. Figures are given for production by states and imports and exports by classes of product and country of origin or shipment. AHE (16)

Plant Book-Keeping and Cost Accounting in Iron and Steel Foundries. (Betriebsbuchhaltung und Kostenrechnung in der Eisen und Stahlgiesserei.) A. Geissel. Vol. 17 of Die Betriebspraxis in der Eisen-Stahl- und Metallgiesserei. Wilhelm Knapp, Halle (Saale), 1932. Paper, 6¼ x 9¼ inches, 136 pages. Price 11.50 RM.

The various factors in foundry costs are explained, suitable forms for recording these factors are shown, and methods of cost calculation from those data are given. H. W. Gillett (16)-B-

International Steel Conditions in 1931. E. T. Good. *Engineer,* Vol. 153, Jan. 1, 1932, pages 11-12.

In all countries the 1931 output of steel will, when all the figures are available, be probably 40% less than the 1929 output. France is operating more nearly normal than any other country. Compared with pre-war prices all construction materials are more expensive, except steel. Science and inventions will find it difficult to improve these other materials but improvements in steel are constantly being made. So it seems reasonable to assume that the steel trade will improve considerably when financial and political matters become normal. Production and import and export figures are given. LFM (16)

Sintering Economics. Perry G. Harrison (Evergreen Mining Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 480. Feb. 1932, 9 pages.

Gives estimated costs for sintering various iron ores and flue dusts in a Dwight-Lloyd. Cost for various localities as well. Concludes that Lake Superior ores carrying less than 15% moisture are sintered more economically at Lake front steel plants: over 15% moisture at mine, and never at interior furnace plants. The 2 reasons for sintering are to improve structure and to eliminate moisture and other volatiles. JLG (16)

Some Factors Concerning Silver Price. Cortlandt W. Handy. *Mining & Metallurgical Society of America, Bulletin* No. 223, Vol. 25, Jan. 1932, pages 19-37.

The question of rehabilitating Ag is treated not from the angle of obtaining or even fixing a higher price for Ag but with the point in view that whatever the price is it must be sustained by fundamental economic demand; a Au standard currency can do this just as well as bimetallism in the opinion of the author. The discussion on this point shows very wide disagreement. Ha (16)

Vanadium, Uranium and Radium in 1930. Frank L. Hess. *Mineral Resources of the United States,* 1930, *United States Bureau of Mines,* Part 1, Dec. 14, 1931, pages 133-150.

In 1930, V production was practically confined to Peru, Northern Rhodesia, South West Africa, western Colorado and southeastern Utah. Production figures for the United States cannot be given. The Belgian Congo ores dominate the U-Ra market. An annoted bibliography of 61 references is given. AHE (16)

Cobalt, Molybdenum, Tantalum, Titanium, and Various Rare Metals in 1930. Paul M. Tyler & Alice V. Petar. *Mineral Resources of the United States,* 1930, *United States Bureau of Mines,* Part 1, Jan. 14, 1932, pages 267-296.

No production of Co in the U. S. has been reported to the Bureau of Mines since 1921. Belgium is the principal source, furnishing 81% of the value of the Co and Co ore imported into the U. S. in 1930. (16 references). Domestic production of Mo ore in 1930 was 3,618 short tons of concentrates containing 6,205,000 lbs. (average 85.75%) of MoS_2, slightly less than 1929, but substantially greater than any previous year. There were no imports. The U. S. furnishes more than 85% of the world's supply of ore; the remainder comes chiefly from Norway with smaller shipments from Australia and Canada. (22 references). The production of Ta minerals in the U. S. in 1930 (S. D. & N. M.) was 5,100 lbs., compared with 22,117 lbs. in 1929 and 34,899 lbs. in 1928. Imports were 8,474 lbs. (15,250 lbs. in 1929). Uses are reviewed. Australia is the leading source of Ta ores. (35 references). The Ti industry made marked progress in 1930. Domestic production is confidential. (62 references). AHE (16)

Gold, Silver, and Copper in Wyoming in 1929. Chas. W. Henderson. *Mineral Resources of the United States,* 1929, *United States Bureau of Mines,* Part 1, 1931, pages 271-273.

In 1929 Wyoming produced $1,766 worth of Au, Ag and Cu ($1,083 in 1928). 4 references. AHE (16)

Review of the Silver Market for 1931. *American Metal Market,* Vol. 39, Jan. 6, 1932, page 3; Jan. 7, 1932, pages 3, 7 and 10.

Economic discussion of production and sales, especially buying by India and China. As to the future of Ag, the writers have strong faith that its present plight will be corrected when international finances are adjusted and improvement occurs in world trade and prices. DTR (16)

Taking the Pressure out of Depression. Charles W. Hardy. *Metal Industry,* N. Y., Vol. 30, Apr. 1932, pages 155-156.

Advice is given on how to reduce overhead and other costs. PRK (16)

1 **The Present Status of the Mining and Iron Industry in Brazil. (Der gegenwärtige Stand des Berg- und Hüttenwesens in Brasilien.)** F. W. Freise. *Berg- und Hüttenmännisches Jahrbuch,* Vol. 80, Mar. 15, 1932, pages 1-7.

The article gives a survey on the Brazilian deposits of Au, Mn ore, coal, other ores, as bauxite, Ni ores, chromite, and precious stones. The iron industry is still rather undeveloped. Production statistics are included. 12 references. GN (16)

Scientific Rate Setting in Foundries. T. M. Harrison. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 3, Jan. 1932, pages 650-660.

2 Rate setting as applied to mold and core-making operations is illustrated and described. CHL (16)

Let Us Check Our Readiness for Starting Aluminum Combines. N. S. Haritonenkov. *Light Metals,* Feb. 1932, pages 1-4. (In Russian.)

Since the responsible men in the Al industry were criminally persecuted for stating that Al cannot be commercially obtained from low grades bauxites, nephelines, clays, etc. the industry began to develop rapidly. It is at the present behind any other branch of metallurgy in USSR. 2 of the plants which were to operate in 1932 with the production of 26,000 tons of Al per annum are not even built as yet.

3 Absolute lack of organization is responsible for this. (16)

Gold, Silver, Copper, Lead and Zinc in the Eastern States in 1931—Advance Summary. J. P. Dunlop. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 116, May 27, 1932, 1 page.

10 placers and 17 lode mines in the Eastern states in 1931 produced Au $23,827; Ag $18,545, 63,949 oz.; Cu $2,124,486, 23,346,000 lbs.; Pb $590,076, 7,974 tons; and Zn $15,422,112, 156,697 tons; decreases in quantity and value for all. AHE (16)

Report 57 of Committee on Economy of Operation of Verein deutscher Eisenhüttenleute. Studies for comparing costs of 9 German sheet finishing mills. DTR (16)

Automobiles Lead in Alloy Steel Use. J. D. Knox. *Steel,* Vol. 90, Jan. 4, 1932, pages 134-135.

5 In 1931, the automotive industry continued to lead in the consumption of alloy steels, with the machine tool industry and the agricultural industry coming second and third, respectively, while the railroads advanced from fifth to fourth place. There was a sudden increase in the use of cold-drawn alloy steel bars during 1931 and an increase in the consumption of corrosion-resistant alloy steels, new uses for the latter being found in dairy machinery and in turbine construction. The development of low alloy steels containing Cr, Mn and Si during the year promises to be of industrial importance. JN (16)

The Metaline Lead-Zinc District. Lewis P. Larsen. *Advance Paper, American Zinc Institute,* Apr. 1932, 6 pages.

6 A review of the geological and metallurgical conditions of the Metaline district in the state of Washington near the Canadian border. The ores average about 9.2% Zn and 2% Pb and produced in 1931 11 million lbs. of Zn and 2¼ million lbs. of Pb. Comparative figures of production cost are given with other places of production. Ha (16)

The Engineering Outlook. I. Economic Retrospect and Prospects for 1932. *Engineering,* Vol. 133, Jan. 1, 1932, pages 17-18.

Monthly iron and steel consumption figures are given for the years 1924 to 1931 inclusive. Production index figures are given for the same years using 1924 as the base figure. LFM (16)

7 **Aluminum Production in Russia (La fabrication de l'aluminium en Russie).** *Journal du Four Electrique,* Vol. 41, May 1932, page 168.

The Volkoff aluminum plant with the theoretical yearly capacity of 5000 tons is now ready to operate but with imported raw materials. A larger plant now in construction expect to use a new process of alumina manufacture developed by Kouznetzoff and Joukowsky by substituting in a Norwegian process of Pedersen lime with barium carbonate. The mix is melted in an electric furnace, with carbon and iron scrap additions, ferro silicon eliminated magnetically and the barium aluminate leached. It is regenerated with soda. JDG (16)

8 **A List of Electric Steel Plants in Germany. (Liste des aciéries électriques en Allemagne).** *Journal du Four Electrique,* Vol. 41, May 1932, pages 168-169.

A list of plants in Germany which have electric furnaces with their number and capacity. JDG (16)

Statistical Compilations on Lead, Copper, Zinc, Tin and Aluminum. *Metallgesellschaft,* Apr. 1932, pages 42-52.

Detailed data on world production, prices and foreign trade in the metals named for the years 1928-1931 are compiled. Ha (16)

9 **Recent Developments in Electrolytic Zinc.** Arthur Zentner. *Advance Paper, American Zinc Institute,* Apr. 1932, 8 pages.

A review of the total Zn production of the world since 1920; the percentage of electrolytic production of the total increased from 10.50% to 27.31% in the U.S.A. and from 7.91 to 32.74% for the world during this time. Ha (16)

Metal Price Fluctuations. *American Metal Market,* Vol. 39, Jan. 5, 1932, page 3.

Monthly averages for past 7 yrs. plotted on a percentage basis with averages for 10 yrs., 1904 to 1913, representing normal pre-war values are given for Sn, electrolytic Cu, Pb, Zn, Sb, Al and pig iron. DTR (16)

10 **Roumanian Fuel and Iron Resources.** *Engineering,* Vol. 133, Apr. 15, 1932, pages 467-468.

Brief article stating that Roumanian Fe ores are being conserved by restricting production awaiting further prospecting. Home production meets the requirements in iron and 80% of the requirements in steel. Steel production is steadily increasing. LFM (16)

Consumption of Silver in the Arts and Industries of the United States. CHARLES WHITE MERRILL and the staff of the Common Metals Division. *United States Bureau of Mines Economic Paper* 14, 1932, 18 pages.

The consumption of Ag has increased very slowly; the quantity of new Ag used was only 18% greater in 1929 than in 1911 (Pb and Zn doubled over this period). Consumption of Ag by industries making products for ultimate consumption in 1928 and 1929 was 25,826,554 and 28,601,311 fine ozs., respectively. The division of these amounts among the industries in 1928 and 1929 was, respectively: Sterling Ag 36.4%, 34.4%; photography 25.4%, 26.6%; electroplating 14.9%, 14.4%; jewelry, optical goods and novelties 8.6%, 9.0%; industrials, including Ag solder 6.6%, 6.9%; chemicals 6.0%, 6.2%; dental supplies 1.9%, 2.1%, miscellaneous 0.0%, 0.3%; losses 0.2%, 0.1%. AHE(16)

Lead Industry in 1931—Advance Summary. H. M. MEYER. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 119, June 8, 1932, 3 pages.

Output of refined primary Pb from domestic ores in the U. S. in 1931 amounted to 390,260 short tons valued at $28,879,000, a decline of 32% in quantity and 50% in value from 1930. Production of refined Pb from foreign ore (chiefly Newfoundland, Mexico and Canada) decreased 24% to 52,504 short tons. About 38% of domestic production was from Mo., 26% from Id., and 19% from Utah, compared with 35, 23 and 21% in 1930. Antimonial Pb produced at primary smelters totaled 21,842 tons, containing 3,575 tons of primary domestic Pb, 1,568 tons of primary foreign Pb, 768 tons of primary domestic Sb, 196 tons of primary foreign Sb, 14,173 tons of secondary Pb and 1,474 tons of secondary Sb. AHE (16)

Zinc in 1930. ELMER W. PEHRSON. *United States Bureau of Mines, Mineral Resources of the United States,* 1930, Part I, Apr. 25, 1932, pages 431-477.

The production of primary Zn in the U. S. amounted to 498,045 tons in 1930, a decrease of 20% from 1929, the lowest output since 1922. Of the total, 98% was produced from domestic ores and 2% from foreign ores, the former decreasing 20% and the latter 35%. Electrolytic Zn amounted to 26.3% of the total primary output, 25% in 1929. The apparent deliveries of primary Zn to domestic consumers decreased 28% and the industrial use of primary and secondary slab Zn declined 24%. World smelter production (1,524,000 short tons) decreased 5% in 1930. The largest tonnage decreases occurring in the U. S., Belgium and Great Britain, Canada, Norway, Northern Rhodesia, Poland and Mexico showed substantial tonnage increases. AHE (16)

The Point System for Determining Molding Piece Rates. W. J. MACNEILL. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 3, 1932, pages 645-647.

A method is given by which the molding costs may be estimated quickly. CHL (16)

Replacement of Obsolete Materials is Dictated by Economy. H. E. MACK. *Steel,* Vol. 90, Jan. 18, 1932, pages 23-25.

A plea for the discarding of many obsolete materials and out-of-date specifications by machinery manufacturers in favor of a smaller number of standard steels and nonferrous metals of more recent development. JN (16)

Mercury Industry in 1931—Advance Summary. H. M. MEYER. *United States Bureau of Mines, Mineral Market Reports* No. M.M.S. 103, Apr. 8, 1932, 2 pages.

Domestic production of Hg in 1931 increased 15% in quantity to 24,750 flasks, and decreased 13% in value to $2,162,000. Stocks increased during the year. Production was suspended at most mines at the end of the year. California produced 54% of the country's total (16% increase over 1930), Oregon increased production 71% to rank second, Nevada's production declined 33%, production in Texas was considerably higher and Arkansas produced Hg for the first time. Imports were only 356 flasks, as compared with 2,943 in 1930 and 14,292 in 1929. AHE (16)

Gold, Silver, Copper, Lead and Zinc in Montana in 1930. T. H. MILLER. *Mineral Resources of the United States,* 1930, Part I, Feb. 24, 1932, pages 385-429.

The output of Au, Ag, Cu, Pb and Zn from Montana mines in 1930 was valued at $32,720,416, a decrease of more than 54% from 1929, of 35% from the yearly average for the decade 1921-30, and was less than any other year except 1921 since records began in 1904. Mont. ranked 2nd in Cu production, 3rd in Ag, 8th in Zn. Au output $(899,001) declined more than 20% from 1929 and 36.7% below the average for the past 10 years; it was the lowest output since records were started in 1904. Ag production (7,052,899 ozs., $2,715,362) decreased nearly 60% in value and 45% in quantity, was 38% less than the yearly average for the decade, and except for 1921 was the lowest production since 1904. Cu output decreased 34% in quantity and 51% in value to 196,187,523 lbs. worth $25,504,378. This was 10% less than the average output since 1921 and was the lowest since 1922. Pb production (21,306,044 lbs.) decreased 46% from 1929 and about 56% in value to $1,065,302. Zinc output was 52,841,108 lbs. valued at $2,536,373, decrease of 61% in quantity and 72% in value from 1929. This is 56% less than the decade average and the lowest output since 1921. AHE(16)

Lead in 1930. ELMER W. PEHRSON. *Mineral Resources of the United States, United States Bureau of Mines,* 1930, Part I, May 3, 1932, pages 479-514.

Total production of pig Pb in the U. S. in 1930 decreased 15% to 772,033 short tons. Production from domestic ores and base bullion decreased 15% to 563,740 tons, and from foreign ores and base bullion 32% to 69,293 tons, a total reduction of 17% in refined primary Pb to 643,033 tons, less than any year since 1923, and having a value 34% less than in 1929. The total Pb from foreign materials was 11% of the total in 1930, 13% in 1929. Production of pig Pb from secondary materials decreased 7% to 129.000 tons. About an equal amount was recovered in alloys. World smelter production was 1,830,000 tons, divided as follows: U. S. 33, Mexico 13, Australia 10, Canada 8, Spain 7, all others 29, the U. S. decreased from 36% in 1929 and Spain from 8%; "all others" increased 4%, the balance were the same. Production by states, districts and countries is discussed. Figures on consumption by uses are given. AHE (16)

PLANTS & LABORATORIES (17)

Steel Pressings for Automobiles. *Iron & Coal Trades Review,* Vol. 124, Apr. 1, 1932, pages 549-550.

The plant of the Pressed Steel Co., England, for the production of automobile bodies is described in detail. Ha (17)

The Electric Furnace Installation of the Ford Factory in Koeln-Niehl. (Die Elektroofenanlage der Ford-Fabrik in Köln-Niehl.) E. SCHMIDT. *Elektrowärme,* Vol. 2, Apr. 1932, pages 91-95.

— 9 furnaces with a total of 1410 kw. for annealing, hardening and drawing are installed. The installation for continuous operation is fully described and illustrated. Ha (17)

The Northwest Lead Co. J. W. GWINN (Bunker Hill & Sullivan Mining and Concentration Co.). *Mining Congress Journal,* Vol. 17, Nov. 1931, pages 628-629.

8 Description of this plant is given in detail for manufacturing of pure Pb products, antimonial pipe and white Pb and Pb specialties. No solders, babbitts or mixed metals are produced. Raw materials are Bunker Hill 99.99% pig Pb, Wah Chang Circle Brand Sb and small amount of pure Cu for special sheet and pipe alloy specifications. 3500 to 4500 — tons of Pb are manufactured per annum. There is a sheet Pb department for pure chemical sheet Pb and one for antimonial sheet Pb. Pure sheet Pb is furnished in sizes from 1 lb. to 60 lbs./ft.^{2}, and from 8 to 9 ft. wide and up to 55 ft. long. Antimonial sheets are supplied in Sb percentages from 1 to 10%, and in sizes specified by a customer. The 9 Pb pipe department operates chiefly with Northwest Lead Co.'s patented equipment. The press equipment produces over 225 pipe sizes, each ranging from seamless tubing to 12" inside diameter, with ¾" wall material. In addition, there is produced light wire, strip Pb, plumbing fittings, Bunker Hill brand lead wool, special equipment for pulp — and paper mills, chemical plants, smelters and reduction works. DTR (17)

Malleable Castings. J. B. NEALEY. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1062-1064.

10 Description of the plant of Stockham Pipe & Fittings Company, Birmingham, Ala. Recent innovation in pouring of castings is a motor-operated platform on which the operator stands, running parallel to the flask conveyor and a ladle trolley parallel to both. Core-ovens, malleablizing furnaces, furnaces for heat treating steel castings and galvanizing kettles are fired by gas. Malleable castings are — packed in alloy steel boxes. MS (17)

MISCELLANEOUS (20)

Influence of High-Frequency Oscillations on Metallurgical Products. (L'Influence des Oscillations à haute fréquence sur les Traitements des Produits Metallurgiques.) G. Mahoux, with comments by L. Guillet. *Genie Civil,* Vol. 98, Jan. 1931, pages 41-42.

Magnetic susceptibility is greatly increased if the pieces under treatment are subjected to electromagnetic oscillations of high frequency. The tests so far made indicate great practical possibilities and are to be continued. Nitration is hastened and Ni deposits on the surface of steel are absorbed at 450° C. Ha (20)

The Calculation of Aeroplane Stringers for Stiffness. (Zur Berechnung auf Knickbiegung beanspruchter Flugzeughohne.) Alfred Teichmann. *Luftfahrtforschung,* Vol. 9, Dec. 1931, pages 85-134.

The investigation is an analytical treatment and development of a method to calculate beams and stringers of aeroplane considering some factors which hitherto have been neglected; for instance the reinforcing effect of ribs between the stringers is taken into account and also the multiple support of one through-going beam if the supports are not all in one line. To facilitate the evaluation of the developed formula tables with numerical values are given. Ha (20)

New Experiences with Electric Gas Purification Plants. (Neuere Erfahrungen mit elektrischen Gasreinigungsanlagen.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Mar. 20, 1932, page 162.

Brief discussion of experiences on electric gas purification plants working according the Cottrell method. GN (20)

Progress Report of Pipe Joint Research. K. R. Knapp. *American Gas Journal,* Vol. 136, Apr. 1932, pages 39-43.

Design factors for successful performance of leak clamps are outlined along with the proper preparation of a joint about to receive such a clamp. Recommendations are made as to proper and improper types of joints under specific conditions. Test methods used in the research are explained in detail. Future activities include the study of cast iron bell and spigot joints and a detailed study of arc welding. CBJ (20)

The Action of Fusible Reaction Products or Pre-formed Eutectics on the Amounts of Conversion in Reactions of Powder Mixtures. (Ueber die Einwirkung von schmelzbaren Reaktionsprodukten oder vorausgebildeten Eutektika auf die Umsetzungsbeträge bei Reaktionen in Pulvergemischen). J. Arvid Hedvall & Ingemar Bergstrand. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 205, Apr. 20, 1932, pages 251-256.

The influence of ions and other admixtures in the conversions on the conversions in the solid state was investigated with special reference to eventual eutectics by using halides. It was found that for instance, CaO and BaO react already at fairly low temperatures with $PbCl_2$. If larger amounts of a melt are formed the conversion is considerably greater than if only solid materials reacted. If the amount of melt becomes so large that the conversion is increased the action is greater if a eutectic has been formed previously than if the components are joined after the beginning of the reaction. Small amounts of a melt as they are represented by certain impurities have no appreciable influence on the course of the reaction. Ha (20)

Investigation of the Method of Determining the Relation of Statical Hysteresis and Flexural Stress by Measurement of the Decrement of a Freely Vibrating U Bar. G. H. Keulegan. *Bureau of Standards Journal of Research,* Vol. 8, May 1932, pages 635-656.

To determine whether measurements of the decrement of a vibrating U bar could be used to measure with sufficient accuracy the statical hysteresis of a given material, the statical hysteresis of a U bar of Armco iron was first measured under cyclic static loading, and then the decrement of the vibrations of the same material was measured. The results of the experiment showed that within the limits of the accuracy of the approximate theory used, both methods gave equivalent results. For stresses above a certain small threshold value, it was found that in Armco iron the energy lost by statical hysteresis varied approximately as the cube of the amplitude of the maximum stress. WAT (20)

Silicon Carbide and Electro-Corundum. (Siliziumkarbid und Elektrokorund.) R. Schneidler. *Tonindustriezeitung,* Vol. 56, Jan. 25, 1932, pages 105-107.

The article outlines the theoretical principles of the production of silicon carbide, discusses the practical manufacturing and its application as grinding material and refractory. Along the same line, properties, production, and application of corundum are discussed. 1 reference. GN (20)

The Foundry Apprentice. C. Sherriff. *Foundry Trade Journal,* Vol. 46, Apr. 14, 1932, page 236.

Suggestions are made as to the grading of boys into 3 groups after a probationary period in the foundry—*Grade A:* Boys keen, interested, and capable of general foundry work; *Grade B:* Boys capable and satisfied to do molding only; *Grade C:* Boys who dislike the smell, dirt, and general conditions of a foundry, and who should be immediately dismissed. OWE (20)

On the Plastic Behavior of Metals. (Über das bildsame Verhalten von Metallen.) W. Prager. *Naturwissenschaften,* Vol. 19, Aug. 7, 1931, pages 681-685.

The theoretical treatise takes the following steps: Introduction, conditions of flow, correlation of stresses to deformations and the statically defined problems of the plasticity theory. EF (20)

Suspension Bridge Stresses Determined by Model. George E. Beggs. Elmer K. Timby & Blair Birdsall. *Engineering News-Record,* Vol. 108, June 9, 1932, pages 828-832.

Application of model study to the Mt. Hope bridge in Rhode Island gave results so close to analytical design values that model analysis was adopted for preliminary and check design of the Trans-Bay bridge at San Francisco. Live-load and temperature stresses and deflections are solved mechanically by means of a steel model. Principles of model design, construction and analysis are explained in detail. CBJ (20)

Prevention of Smoke in Metallurgical Operations. C. H. Desch. *Iron & Steel of Canada,* Vol. 15, Apr. 1932, pages 37-38, 47.

Paper presented to the 3rd International Conference on Bituminous Coal. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 49. OWE (20)

Revamping a 28-year-old Steel-Truss Bridge. James P. Exum. *Engineering News-Record,* Vol. 108, May 26, 1932, pages 757-758.

Viaduct in Kansas City was damaged by fire, corroded from locomotive gases and worn by long service. Replacement of a wood floor by steel and concrete on spans over railroad tracks, reinforcement of eyebars by welding, and general repairs put the structure in condition for many more years of useful service. CBJ (20)

Influence of a Discovery Relating to the Production of Electrical Energy on the Evolution of the Chemical and Metallurgical Industries. (De l'Influence d'une Découverte dans la Production de l'Énergie Électrique sur l'Évolution des Industries Chimiques et Métallurgiques.) Henry Gall. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 92-95.

The paper is an address presented by the President of Société de Chimie industrielle. It outlines briefly the great and rapid progress made in the electrochemical industries, such as followed from the use of electrolysis in solutions, of fused salts and of the electric furnace, as a result of the invention of the dynamo by Gramme. MAB (20)

Explosive Disintegration of Acetylene in High-Pressure Producers. (Decomposition Explosive de l'Acetylene dans les Generateurs á haute Pression.) M. Fassbinder. *L'Usine,* Vol. 41, Feb. 5, 1932, page 31.

Although, according to the theory of Berthelot, the danger of the formation of highly explosive mixtures of acetylene under high pressure is always present yet the practical conditions, as for instance the dilution with inert gases preclude almost entirely all danger of explosion at the usual temperature of the surroundings. A very slight addition of illuminating gas reduces the risk very considerably. Several experiments made in this respect are briefly described. Ha (20)

On The So-Called Elden Meteorite. Robert E. S. Heineman. *American Journal of Science,* Vol. 23, May 1932, pages 417-420.

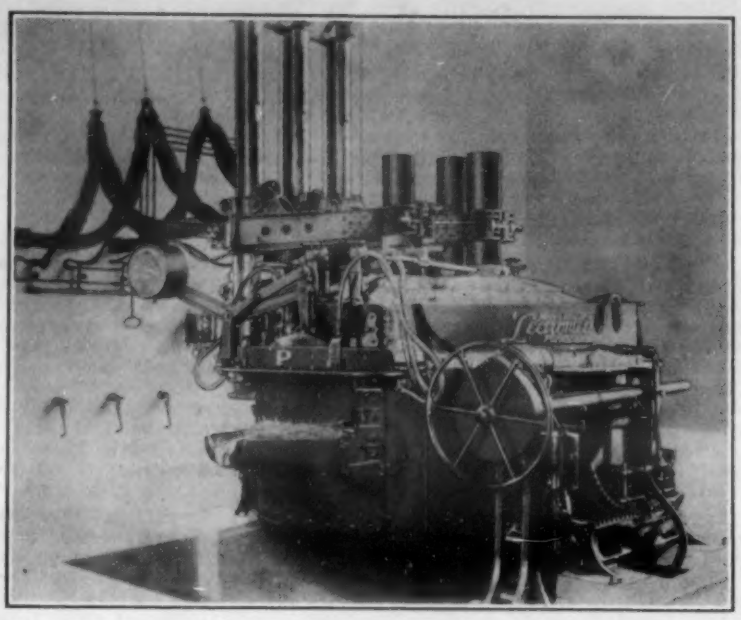
A unique object of suspected meteoric origin was found in 1927 near Flagstaff, Arizona. The mass consists of a graphite matrix veined with irregular intersecting bands composed of grains of metallic Ni-Fe. The results of a chemical analysis are: Metallic Fe 37.440, Fe as $FeCl_3$ 0.680, Fe as FeO 3.287, S 0.073, Si 0.432, Mn 0.120, Cl as $FeCl_3$ 1.300, P 1.110, Ni 4.040, Co 0.047, C as graphite 46.530, combined C 2.202, O as FeO 0.943, insoluble, mainly FeO and SiO_2 1.796. Flagstaff is about 35 miles in an air line from the Meteor Crater and is supposedly in the direction from which the meteor came. The specimen described could have been an outrider of the main swarm. WAT (20)

Steelmakers Strive for Low-Cost, High-Quality Ingots. *Steel,* Vol. 90, Jan. 4, 1932, pages 157-170.

The past year has witnessed an increase in the number of waste heat boiler installations. These boilers effect a recovery of about 23% of the heat input to the furnace. The use of automatic combustion control equipment has increased steadily, there being now over 50 open-hearth furnaces supplied with such equipment. The use of natural gas as an industrial fuel promises to be extended in the future. The manufacture of silica brick for open-hearth roofs has been greatly improved and the use of chrome brick refractories and high alumina brick has increased considerably during the year. JN (20)

The Development of the Scientific Heat Principles of Steam Boiler Construction. (Die Entwicklung der wärmewissenschaftlichen Grundlagen des Dampfkesselbaus.) H. Bonin. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Feb. 1932, pages 57-62.

The properties of steam, pressure and temperature in the saturated state, the total heat, specific volumes, critical pressure and temperature, specific heats, heat transition, and gas radiation are determined. The accuracy attained, the manner in which the tests were carried out, the fuel and combustion processes, the specific heats of waste gases, and the measurement of the temperature are discussed. MAB (20)



Standards Yearbook, 1932. For sale by Superintendent of Documents, Washington, D. C. Cloth, 6¼ x 8¼ inches, 394 pages. Price $1.00.

This volume starts with a symposium on standardization in communication. The activities of some 20 international standardizing agencies are then discussed, and the work of national standardizing laboratories in the United States, England, Germany, France, Canada and Japan is briefly outlined. National Industrial Standardizing bodies of 21 countries are mentioned.

The work of Federal Standardizing Agencies is discussed, special attention being given to that of the Bureau of Standards. A list of new Federal Specifications is given, and addresses of State Purchasing Agencies are included. The work of the American Standards Association, American Society for Testing Materials, American Marine Standards Committee and the Central Committee of Lumber Standards is described. Names, addresses of officers, and an outline of the activities of 416 trade associations, scientific and technical societies and other agencies concerned in joint action on standardization and allied matters are given. This is rather all inclusive, the Amateur Athletic Union of the United States, National Collegiate Athletic Association, the Intercollegiate Association of Amateur Athletes of America, Joint Basket Ball Rules Committee, the National Association of Golf Club Manufacturers, and the Sporting Arms and Ammunition Manufacturer's Institute are there. We find listed the National Association of Mopstick Manufacturers and the National Lightning Rod Manufacturer's Association, as well as all the metallurgical trade associations.

The book is a good reference volume for finding out what type of standardization activities are going on in any field. It gives no detailed technical information.

FOUNDRY PRACTICE & APPLIANCES (22)

Experiences with Die Casting. Zinc, Aluminum and Brass Die Casting. (Erfahrungen beim Spritzguss. Zink, Aluminium- und Messing- Spritzguss.) H. WALCHENBACH. *Werkzeugmaschine,* Vol. 36, May 31, 1932, pages 180-184.

1 The paper deals with practical experiences in die casting Zn, Al and brass. The accuracy of dimensions and the tolerances of die castings are considered. The savings in weight by die casting Al alloys are given. The savings in time and money to be effected by subsequent working and machining are stated. The prices of some auxiliary automobile parts made from Al sand and die casting alloys are compared. The composition of good die casting alloys is tabulated. The construction of the dies is considered with special reference to the flow of the metal which has particularly to be borne in mind. The wall thicknesses of die castings should be as uniform as possible. GN (22)

The Alloying of Copper with Tin and Antimony. (Das Legieren von Zinn mit Kupfer und Antimon.) *Deutsche Goldschmiedezeitung,* Vol. 35, Apr. 16, 1932, page 4.

2 Suggestion for the melting of alloys of Cu with the use of a preliminary alloy. GN (22)

Molds in Oblique Arrangement. (Schräg angeordnete Gussformen.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 29, 1932, pages 215-216.

3 It is shown that long articles are suitably cast with an oblique arrangement of the mold. The casting from 2 sides of such articles offers disadvantages due to the formation of pipes. This is avoided by the new method. GN (22)

Small Machine for Dressing Molding Sand in Foundries. (Kleinmaschine für die Formsandaufbereitung in Giessereien.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 10, 1932, pages 279-280.

Description of the machine which separates Fe particles from the molding sand. GN (22)

Foundry Factors in Design of Steel Castings. W. G. HANAWALT. *Journal Society of Western Engineers,* Vol. 37, Apr. 1932, pages 82-87.

4 Correct design and application of steel castings involve a competent knowledge of foundry practice. Advantage should be taken of the various types of alloys available, also of heat treatment and metallurgical facilities. WHB (22)

The Determination of Unit Price for Simple Small Foundry Castings. (Het bepalen van stukprijzen voor eenvoudige kleinere gietstukken.) G. HOFSTEDE KOOPMAN. *Die Gieterij,* Vol. 6, Apr. 1932, pages 42-43.

5 The author reproduces in form of a table, with the method of use, the results obtained by the Federal Malleable Company of Milwaukee, Wisconsin, U.S.A., after 10 years research on this subject. The author states that the table can be safely used in determining prices of all small castings requiring no other stamping than by press. It also applies to 80% of the cases of hand-stamping when this is not too intricate. MPW (22)

Molding of Insulator Caps Made of Steel or Malleable Cast Iron. (Rationelles Formen von Isolatorkappen in Stahl und Temperguss.) M. HONOLD. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Feb. 21, 1932, pages 73-75.

6 The article outlines the various procedures to be followed in molding insulator caps to be made either of cast steel or malleable cast iron. GN (22)

A Modern High-Capacity Molding Equipment (Neuzeitliche Hochstleistungs-Formeinrichtung). B. KUERTEN. *Die Giesserei,* Vol. 19, Apr. 29, 1932, pages 168-169.

A semi-automatic arrangement for molding smaller parts such as grates, pipes, brake blocks, radiators, etc. in quantity production is described which can be adjusted so as to fill, tamp and finish small and large molding boxes. Ha (22)

A Steel Casting of Nearly 300 Tons. (Un Moulage d'acier de près de 300 Tonnes.) LEBRULY. *Revue de Fonderie Moderne,* Vol. 26, Feb. 10, 1932, pages 39-41.

7 Describes the molding and casting of a base plate of a hydraulic press, width 3.10 m., height 3.90 m., length 7.10 m.; weight 290 tons. Ha (22)

The Manufacture of Large Marine Engine Castings. *Foundry Trade Journal,* Vol. 46, Apr. 7, 1932, page 215.

FURNACES & FUELS (23)

Immersion Melting with Gas. E. B. Dunkak. *Metal Progress,* Vol. 21, Mar. 1932, pages 73-77.

Melting and heating liquids, salts and metals by means of submerged, gas fired heating units is practical up to 1800° F. The advantages of immersion heating are fuel economy, ease and rapidity of temperature control and reduction of dross loss. WLC (23)

Developments in Gas Producer Practice. Victor Windett. *Rolling Mill Journal,* Vol. 5, June 1931, pages 427-430.

Abstract of a paper presented before the American Iron & Steel Institute in New York, May 22, 1931. See *Metals & Alloys,* Vol. 2, Oct. 1931, page 230. The author discusses the history, early developments, outstanding features, and the modern developments and improvements in the construction, operation and control of mechanical gas producers. He attributes the notable increase in gas producer capacity to complete mechanization and to the wide-spread application of instrumental control of operation. JN (23)

Industrial Furnaces for Gas. XIV. Industrial Ovens—General. XV. Ovens for Core Baking. Lawrence E. Biemiller. *American Gas Journal,* Vol. 136, Apr. 1932, pages 34-36; June 1932, pages 27-28.

The use of gas for drying operations such as core baking, mold drying, japanning, enamel, paint, and lacquer drying, lithographing, armature baking, ceramic and chemical drying, drying of foodstuffs, and many others, and the principles of oven construction, insulation, and ventilation are discussed. The use of cores and typical core mixes as well as core making practice are outlined. Cores are baked in either batch or continuous ovens. The design and operation of each type of oven are described. Core baking in continuous ovens results in large economies as a result of correct layout of oven and other related equipment. A plan view of an airplane motor foundry is shown. CBJ (23)

Modernization by Electric Heating. C. L. Ipsen & S. Martin. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 51-52, 55.

From a paper presented before the Associated Industries of Massachusetts, Oct. 1931. Over-all heating costs are discussed. It is only the actual cost of the source of heat that makes electricity appear more expensive. On all other costs, electric heating has a decided credit in its favor, and this may amount to more than the total cost of the source of heat. In treating steel, the total cost of electricity averages about 1% of the over-all cost of the product. Improvement in quality may amount to several %. Practically all heating in the plants of the General Electric Co. within the temperature range of available apparatus is electrical. The heating load at the Schenectady Works is practically equal to the motor load. All sheet steel punchings are annealed in 38 car-type electric furnaces. Large Cu wire and strip are annealed in H_2O-sealed furnaces with steam atmosphere, and fine wire is annealed in the retort type, gas-controlled atmosphere furnaces. MS (23)

The Combustion of Pulverized Fuel. S. B. Jackson. *Iron & Coal Trades Review,* Vol. 124, Mar. 25, 1932, pages 516-517.

The relation of the fineness of particles of powdered fuel to combustion time, heat liberation and temperature, preheating of combustion air and the effect of moisture in the coal are treated theoretically. Ha (23)

Electric Furnace in Automobile Industry. (Le four electrique dans l'industrie automobile.) Serge Heuland. *Journal du Four Electrique,* Vol. 41, Feb. 1932, pages 55-59.

A 3-ton Russ furnace installation at Mathis Works, used principally for making pearlitic cast Fe cylinder blocks is described. JDG (23)

Artificial Furnace Atmosphere Created from Ammonia. John E. Haig. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 48-50; Feb. 1932, pages 124-127.

After enumerating the sources of H and discussing the dissociation of NH_3 the author describes a simple and economical method of generating H_2 and N_2. Liquid NH_3, vaporized by the heat in gas previously dissociated flowing through a worm within the vaporizer shell, passes through a relief-valve, a needle-valve and a reducing-valve into a dissociator consisting of one or more tubes containing a catalyst, an electric heating unit, provision for a thermocouple, and an outer casing inclosing a suitable heat insulator. The NH_3 is dissociated by the catalyst at 1100° F. into 75% H_2 and 25% N_2 by volume. The catalyst is activated in the dissociator by passing through it while heated a stream of H. If pure N_2 or a gas with a lower content of H_2 is desired, the H_2 is burned. For drying the resultant product the gas is passed through a cooler, a condenser, an after cooler and drying towers. The cost of producing H_2 by this method is less than \$5.00/1000 ft.^{3} and for N_2, less than \$2.50/1000 ft.^{3} MS (23)

The Effect of Construction and Operation Methods on Heat Requirements of Pusher Furnaces. (Der Einfluss von Bau- und Betriebsweise auf den Wärmeverbrauch der Stossofen.) Werner Heiligenstaedt. *Archiv für das Eisenhüttenwesen,* Vol. 5, May 1932, pages 559-568.

Total heat requirements for pusher furnaces are given by heat balances. The individual members of the heat balance equations are taken up in order and explained through the help of specific practical problems. Relations between the gas temperature and flue gas loss, amount of charge and hearth surface, furnace wall and cooling water losses, most economical furnace and recuperator size are discussed. DTR (23)

Balanced Hearth Continuous-Flow Normalizing Furnace. *Iron & Coal Trades Review,* Vol. 124, Apr. 23, 1932, pages 665-666.

The desirable features of a normalizing furnace for alloyed steel sheets, particularly facilities for careful handling in order to avoid scratching and damaging, are set forth and a furnace installed at the Ebbw-Vale Works, Wales, is described. Ha (23)

The Brayshaw Gas Heated "Novopress" Furnace. *Iron & Coal Trades Review,* Vol. 124, Apr. 8, 1932, page 590.

The gas and air flow are regulated by a hand wheel which gives correct proportion of gas and air under all conditions of heating, and automatically opens the flue damper. At 900° C. the gas consumption averages about 1.5 ft.^{3}/lb. of load. Ha (23)

REFRACTORIES & FURNACE MATERIALS (24)

Magnesium Orthosilicate as Refractory. (Magnesiumorthosilikat als feuerfester Baustoff.) F. Reinhart. *Tonindustriezeitung,* Vol. 56, Mar. 17, 1932, pages 323-324.

1 Since pure magnesium orthosilicate is rarely to be found as mineral and since it proved excellently fit as refractory material, methods have been developed to produce it artificially. To attain this the German patent No. 417360 uses the following procedure: Magnesium salt as, for instance, $MgSO_4$, is melted together with quartz sand and the magnesium orthosilicate is thus formed at temperatures between 1000° and 1500° C. A later Austrian patent No. 121249 utilizes the magnesium hydrosilicates, as they are available in the form of the minerals talc and serpentine. The method suggested by this patent is described. Due to the high temperature stability and the high resistance to chemical attack magnesium orthosilicate is suitable for use as refractory brick for metallurgical furnaces, glass melting furnaces, as lining for heating furnaces, muffles and the like. The applicability, therefore, is the same as that of aluminum silicate. GN (24)

Works Tests on Refractories and Service Conditions. R. J. Sarjant. *Transactions Ceramic Society,* Vol. 30, Feb. 1931, pages 46-67.

The author discusses the correlation of fundamental, simulative and service tests on refractory materials. In the present state of knowledge the service test must remain the ultimate arbiter in the selection of refractories. Simulative tests have limited application. The preferable course 3 is the development of fundamental tests, which have been shown in a number of cases to give definite indications of performance value. Tables with numerical values of physical properties as expansion, porosity etc., important for steel works practice, are given for a number of materials. Ha (24)

Service of Refractories Is Improved During 1931. *Steel,* Vol. 90, Jan. 4, 1932, pages 168-169.

The year 1931 may be characterized by the wider use of high-alumina refractories of the mullite and sillimanite type, improvements in chrome and magnesite brick, the use of silicon carbide as a refractory to withstand excessive abrasion, and studies on 2 new types of refractories, 4 beryllium oxide and euhedral corundum. Other outstanding developments are a new mineral bonded, hydraulically pressed, unburned magnesite brick for open-hearth wall construction, a new periclase magnesite brick for open-hearth roofs, a new wet chrome cement, and a new plastic chrome coating material. JN (24)

How to Attain a Long Life of Cupola Lining. (Wie erreicht man eine lange Lebensdauer des Ofenfutters im Kupolofen.) A. Bandermann. *Zeitschrift für gesamte Giessereipraxis,* Vol. 53, Mar. 20, 1932, pages 118-120.

5 Practical hints are given as to how to attain cupola linings of high durability. The lining materials best fitted are discussed and the methods of lining are considered. GN (24)

On Recent Ceramic Patents. (Von neueren keramischen Patenten.) H. Hirsch. *Berichte der deutschen keramischen Gesellschaft,* Vol. 13, Feb. 1932, pages 140-148; *Tonindustriezeitung,* Vol. 56, Apr. 14, 1932, pages 407-410.

Including discussion. The new patents are described under the headings: (1) improvement of the raw material, (2) grinding and dressing, (3) shaping, (4) fluxes, (5) special refractories. In the latter group are mentioned patents 6 covering the improvement of refractories by embedding of metals. (6) furnaces, in particular tunnel furnaces. GN (24)

The Action of Carbon Monoxide on Refractory Materials. Part I. Experiments on the Disintegration of Fire Clay Products by Carbon Monoxide. Part II. Further Experiments on the Disintegration of Fire Clay Products by Carbon Monoxide. W. Hugill, H. Ellerton & A. T. Green. *Institution of Gas Engineers, 22nd Report of the Refractory Materials Joint Sub-Committee Copyright Communication* No. 39, Sept. 1931, pages 26-30; Sept. 1931, pages 30-33; *British Refractories Research Association Bulletin* 25, 1931, pages 14-23; Bulletin 26, 1931, pages 32-43.

7 Of 11 specimens 5 resisted disintegration by CO (flow-1 l./hr.) at 420° C. for 20 hrs. Others showed breakdown. Disintegration is mainly localized at the Fe spots. Analysis showed no relationship between Fe content and disintegration. However, less than 0.1% ferruginous matter extracted by bromoform differentiated resistant bricks. Part II. Experiments of I were extended to 200 hrs. Three resisted disintegration. There is no obvious relationship between disintegration by CO and permeability. AHE (24)

Investigations of the Heat Conductivity of Refractory Bricks. (Untersuchungen über das Warmeleitvermögen feuerfester Steine.) Anton Kanz. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Akt.-ges. Dortmund,* Vol. 2, No. 10, 8 1932, pages 223-234.

An improved method of measuring the heat conductivity of refractory materials in the form of a thin plate is described which has the advantage of permitting a quick and accurate determination of the conductivity with compensation for heat losses. The arrangement is fully described and the results of a great number of silica, corundum, bauxite, chromite and other bricks are tabulated. The values found agree very well with those determined by other more complicated methods. It could be stated that silica bricks have 9 a heat conductivity which increases with increasing temperature, more below 400° C. than above. A heat treatment of longer duration which causes formation of tridymite increases the heat conductivity considerably. Other refractories showed irregularities below 300° C., which are very likely due to structure changes. It is recommended to investigate the refractory properties more closely in the range between 100 and 600° C. 13 references. Ha (24)

Magnesite. *British Clayworker,* Vol. 40, 1932, pages 391-392.

The varying conduct of refractories is due to differences both in the chemical composition and physical structure 10 of the raw materials. Trouble with the finished brick is also due to the method of grinding, tempering, and bonding and the system of conducting the drying and final firing. A brief discussion on crucibles prepared from magnesite, and the increased use of magnesite for basic-lined converters in the refining of Cu and Ni and in the metallurgy of Ag is included. WAT(24)

Refractories for the Iron and Steel Industry. THOMAS W. HIND. *Iron & Steel of Canada,* Vol. 15, June 1932, pages 67-69.

Address before the Montreal Chapter, A.S.S.T., in which various refractories which have been of service in the Fe and steel industry are discussed. The physical properties of refractories, the effects of gases and of slag erosion on refractories and the methods of manufacture employed in the production of bricks are described. OWE (24)

Heat Insulation Developed for Every Purpose. B. TOWNSHEND & E. R. WILLIAMS. *Chemical & Metallurgical Engineering,* Vol. 39, Apr. 1932, pages 219-222.

A summary of known data is given as a guide to selecting heat resisting materials. PRK (24)

Structural Materials for Modern Heat Technology. F. H. NORTON. *Chemical & Metallurgical Engineering,* Vol. 39, Apr. 1932, pages 226-228.

Tables and figures give the more important properties of the common types of refractories which are in use. PRK (24)

The Design and Operation of Open-Hearth Furnaces. Part III. C. W. VEACH. *Rolling Mill Journal,* Vol. 5, Mar. 1931, pages 175-178, 190.

The brick used in open-hearth construction should have a high density factor to resist permeation by gases and furnace erosion. Conformity to shape and dimensions so as to produce close joints is also important. The quality of silica brick may best be judged from its density. The old process of hand molding is now largely superseded by the method of "drop molding," which produces a more compact article. The possibilities of molding silica brick under hydraulic pressure promises to revolutionize the industry, producing brick as smooth and dense as polished granite. The continuous or tunnel kiln is coming into wider use for all brick manufacture. Both chrome brick and magnesite brick are now used in basic open-hearth linings. There has been a great improvement in checker construction with silica brick. The new design combines the advantages of the straight perpendicular checker flues with an additional flue at a downward slant of 45°. The author also gives a detailed description of a complete modern furnace of 100-150 tons capacity. JN (24)

The Design and Operation of Open-Hearth Furnaces. Part V. C. W. VEACH. *Rolling Mill Journal,* Vol. 5, May 1931, pages 335-338, 350; June 1931, pages 407-410, 432.

The material used for lining the open-hearth furnace is usually magnesite brick although substitutes such as chrome brick, unburned magnesite, and a mixture of magnesite and cement have been used. The inside dimensions of this magnesite brick lining determine the capacity of the hearth. The bottom of the hearth is usually covered with two or more courses of magnesite brick. It requires from 7 days for a small furnace to 26 days for a 250-ton furnace to "burn in" a new magnesite bottom. In recent years, substitutes for magnesite have been developed from dolomitic clinker. These are cheaper than magnesite and may be used in furnaces that are kept in almost continuous operation. However, the dolomitic clinker must have a silica content of not less than 3% and not more than 9% and must not be used with slags high in silica. The advantages of magnesite furnace bottoms are long length of service and a minimum of repairs. The use of dolomitic clinker bottoms offers a considerable saving in first cost and very little repairs for the first year or two. It is claimed that after a year of service the lime-magnesia contents of the 2 bottoms become quite similar. The author believes that for a 5-year period the dolomitic bottom will show a good margin of economy over the magnesite. The aim in constructing a furnace bottom is to obtain a dense material with a high fusion point, free of pores, and as free as possible of harmful impurities. Even under the best operating conditions, however, corrosion of the bottom will occur from the introduction of foreign elements with the charge. The most harmful of these is silica. Other harmful impurities that occur mixed with steel scrap are Pb, Sn, Cu, Zn, Sb, etc. JN(24)

The Motion Picture as an Aid to Refractories Research. THOMAS S. CURTIS. *Journal American Ceramic Society,* Vol. 15, May 1932, pages 114-123.

The apparatus and technique employed in the study of plastic flow at high temperatures, crystal growth, thermal expansion, vitrification, spalling, etc., are described, and the method of preservation of permanent records of such phenomena in the act of occurrence is given. A description is also given of the physical changes requiring days or weeks for their development which may be depicted in a few minutes on the motion picture screen. WAT (24)

New Refractories Tested in Drive for Lower Costs. HOBART M. KRANER (Westinghouse Elec. & Mfg. Co.) *Steel,* Vol. 90, Jan. 18, 1932, pages 27-28.

Present-day tendencies in the metallurgical field are seen in a wider use of cheaper refractories such as fireclay, mullite and cyanite; the development and more general use of new ramming and patching cements containing corundum, mullite and silicon carbide; the substitution of mullite for silicon in electric furnace roofs and the substitution of chrome brick for magnesia in the bottoms of basic steel furnaces; the extensive use of silicon carbide in places subject to excessive abrasive action; the use of graphite crucibles for melting Al; and the development of a number of new heat insulating materials. JN (24)

The Impermeability of Refractory Materials to Gas. (Ueber die Gasdichtigkeit von feuerfesten Massen.) F. DURAU. *Zeitschrift für technische Physik,* Vol. 13, No. 5, 1932, pages 228-233.

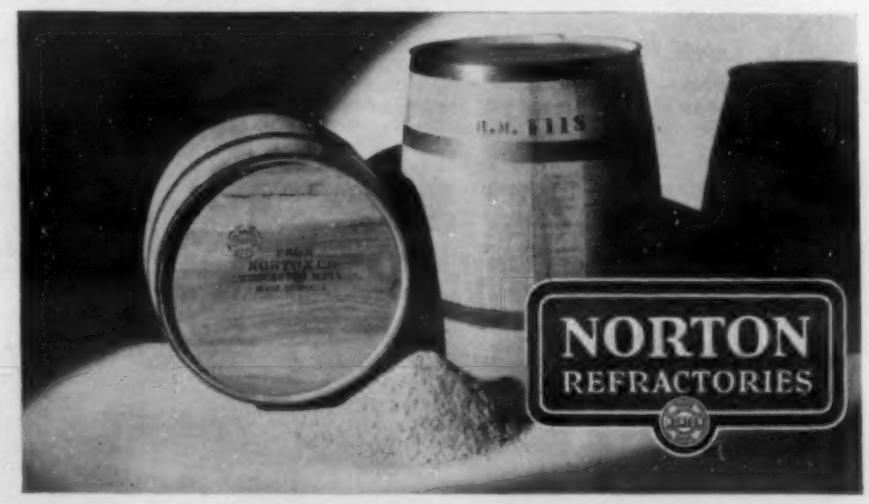
Tests with several kinds of glazed and unglazed tubes showed that at 1200° C. no gas from the inside passes through the walls. On the other hand, gas is continually given off which is ascribed to a disintegration of substances enclosed in material, especially in outer layers. Occluded gases may also be the reason for this phenomenon. Ha (24)

Refractory Joining Cements. A. T. GREEN, F. WHEELER & H. BOOTH. *Institution of Gas Engineers, 22nd Report of the Refractory Materials Joint Sub-Committee, Copyright Communication* No. 39, Sept. 25, 1931, pages 33-41.

The use of the refractoriness-under-load test in the testing of cements is illustrated. AHE (24)

Four-ton Ajax-Northrup Induction Furnace

Long Life Linings
for Large or Small Furnaces



More and more Norton Magnesia Cements are being used in large and small electric induction melting furnaces—furnaces such as the Ajax-Northrup—for ferrous and non-ferrous metals.

Their unusual success is due largely to the fact that there are different Norton mixtures for different conditions—mixtures which do the job for which they were intended and do it well.

Let Norton Magnesia Cements reduce your lining costs. There are also Alundum (fused alumina) and Crystolon (silicon carbide) Cements.

MANUFACTURERS' LITERATURE REVIEWS

1 **Electric Furnaces**—A leaflet issued recently by the Pittsburgh Electric Furnace Co., Pittsburgh, Pa., describes their Lectrosimplex furnace, an inexpensive rapid melting furnace of moderate size. It is available in several sizes and styles.

2 **Stainless Clad Steel**—The Ingersoll Steel & Disc Co., 310 S. Michigan Ave., Chicago, Ill., has issued a folder describing the composition, method of manufacture and fabrication of their stainless clad steel as well as illustrating and listing many applications for this new low cost corrosion resisting material.

3 **Protective Coatings**—A recent pamphlet sent out by the Quigley Co., Inc., 56 West 45th St., New York, N. Y., illustrates a number of applications of their Triple-A protective coatings for preventing corrosion. The distinctive properties of these coatings are described.

4 **Erichsen Testing Machines**—The Bock Machine Co., 3816 Colerain Ave., Cincinnati, Ohio, has distributed a booklet describing the Erichsen machine for testing metal sheets and strips. A detailed description of the test is given as well as directions for the use of the machine. A number of curves show the relation between the thickness and the "Erichsen value" of good metal sheets.

5 **Atmosphere Control Furnaces**—Bulletin 1132 of the Hevi Duty Electric Co., Milwaukee, Wis., describes their method of controlling the atmospheres in their box type furnaces. Specifications for several types of furnaces are given and a cross-section diagram shows how the "Atmosphere Control" works.

6 **Using Paint as Light**—A most attractive booklet issued by the New Jersey Zinc Co., 160 Front St., New York, N. Y., is an A.B.C. summary of a highly technical paper prepared by Mr. Gamble of their Research Division. The simplicity of the charts and the definitions of lighting terms given should enable anyone to solve his lighting problems with ease.

7 **Surface Pyrometers**—Bulletin No. 30 of the Pyrometer Instrument Co., 103 Lafayette St., New York, N. Y., describes their surface pyrometers. A unique feature of these instruments is that contact and reading of temperatures do not have to be simultaneous.

8 **Diamite**—This alloy white iron is discussed in a folder distributed by the Weatherly Foundry & Mfg. Co., Weatherly, Pa. One of its principal features is its great hardness. Castings made from it are recommended for troughs for handling ash, rock and coal, liners for chutes, pulverizer liners, crusher jaws, gears, etc.

9 **Beryllium Copper**—A pamphlet prepared by the American Brass Co., Waterbury, Conn., is devoted to beryllium copper, a heat treatable copper alloy. The heat treated material possesses higher tensile strength, fatigue limit and hardness than any other copper alloy heretofore produced commercially.

10 **Anodes**—A booklet sent out by the Roessler Hasslacher Co., 10 East 40th St., New York, N. Y., describes and illustrates a number of designs of their standard anodes supplied in Purozinc, Duozinc, Cad-a-loy and tin.

11 **Anti-Carbonizing Compound**—A leaflet distributed by the Frederick Williams Co., 125 Cedar St., New York, N. Y., describes their "Nocasine" for use in limiting areas in case-hardening metal parts. It tells when and how to use the compound.

12 **Steel Products**—A complete list of their products has been prepared by the Republic Steel Corporation, Youngstown, Ohio.

13 **Monel Metal**—Bulletin T-5 of the International Nickel Co., 67 Wall St., New York, N. Y., discusses the engineering properties of Monel metal, as to physical constants, strength and ductility, corrosion resistance, working properties, etc.

14 **Constant Temperature Water or Oil Bath**—Bulletin 1220 of the American Instrument Co., Washington, D. C., describes a thermostatically controlled constant temperature bath which holds temperatures to 0.03° C. It is intended for all applications where accurate temperature control over extended periods of time is desired.

15 **Welding Wrought Iron**—A pamphlet issued by the A. M. Byers Co., Pittsburgh, Pa., gives the procedure to be used in welding wrought iron. A number of the outstanding characteristics of wrought iron are discussed. The same company has also issued an abbreviated catalogue of information on wrought iron products.

GENERAL (0)

Report of Ontario Research Foundation for 1931. H. B. SPEAKMAN. Published by H. H. Ball, Toronto, 1932, 34 pages.

The metallurgical department of the Foundation aided some 60 Ontario firms on metallurgical problems in 1931. For 1932 an information service is to be given to all firms of the Province without requiring any membership fee in the Ontario Metal Industries Research Association. Work on causes of failures of metallic materials and similar problems as well as information service and plant visits comprised most of the service work. Research on fundamentals was concerned with preparation of sponge iron from low grade ores, high temperature malleability of carbon and alloy steels, uniformity of heat-treatment of high speed steel in commercial practice, etc. Work has been begun on problems in applied mechanics and mathematics relating to metallurgical materials. HWG (0)

National Physical Laboratory Report for the Year 1931. Department of Scientific & Industrial Research. H. M. Stationery Office, London, 1932. Paper, 8 × 12½ inches, 313 pages. Price 15s.

While this report does not go into technical details, it contains a good many interesting metallurgical high spots. Some of these are in the report of the metallurgical department, and some in that of the engineering department. Among these are the finding that pure, distilled, free from oxide inclusions, Be is, after all, ductile; that heat-treated Cu-Be alloy which has been heralded as of high endurance limit, will require very long-continued test since fracture has occurred after 65 million cycles; that reliable Brinell values, even in steel of 400 Brinell, require that the thickness of the specimen be 20 times the depth of the impression; that wear of steel pivots in sapphire bearings seems to involve chemical combination of the steel with the oxygen of the Al_2O_3; and that nitralloy gages will not "wring" together properly, probably due to Al_2O_3 inclusions.

Beside the continuing work on fatigue, bearing metals and lubrication, thermal conductivity, boiler plate failure, etc., etc., new work is being undertaken on wear testing, and on methods of evaluating the formability of deep-drawing stock. In connection with the work on creep, new equipment has been installed with temperature controlled within about 0.25°C. and deformation measurements made to a hundred thousandth of an inch on a 5 inch test length, or 2 millionths of an inch per inch. The effect of oxidation or of SO_2 attack at high temperatures is being studied in connection with creep problems.

Progress is being made in the preparation of pure iron. Since the Bureau of Standards is also making great progress in this line, it seems likely that knowledge of the properties of really pure iron and its alloys will be considerably advanced in the next few years. H. W. Gillett (0) -B-

Handbook of Inorganic Chemistry. Complex Cyanides of Iron. (Handbuch der anorganischen Chemie. Komplexe Cyanide des Eisen.) Vol. 4, Part 3, Section B, Division 2. Edited by R. Abegg, Fr. Auerbach & I. Koppel. S. Hirzel Verlag, Leipzig, 1932. Paper, 7 x 10 inches, pages B 465-B 674. Price 24 RM.

This section of the treatise on the chemistry of Fe and its compounds deals with complex cyanides of ferrous and ferric Fe. Besides the description of the composition and properties of the compounds, there are chapters on the colloid chemistry of these cyanides and one on the technology of their manufacture. A bibliography of about 1,400 references, dating from 1710 to 1932 is appended.
H. W. Gillett (0)-B-

Metallurgy. EDWIN GREGORY. Blackie & Son, Ltd., London, 1932. Cloth, 6¼ × 9 inches, 284 pages. Price 17s 6d.

This text book is aimed to give engineers an introduction to both ferrous and non-ferrous metallurgy. Obviously not everything that might be included can be covered in so small a volume. The selection of material is rather well done, even though some of the sections appear a bit sketchy. The book is written from the metallographer's point of view, though properties of materials and engineering uses for which they are fitted are not neglected. Corrosion is dealt with briefly, chiefly in connection with 18 and 8. High temperature properties are also briefly discussed, this section being marred by almost unrestrained acceptance of the "time-yield" method as a short cut. Fatigue might well have received mention along with the other causes of failure.

The instructions for calibration of pyrometers, to take the freezing point of NaCl and correct the pyrometer readings in accordance with that calibration if they come within ± 10° of 800°C. hardly seem adequate for many industrial uses of pyrometers in metallurgy.

Relatively few references to the literature are given, and many incidental comments, such as the statement that flaky alloy steel is due to local carbon segregation, producing tiny areas of an air hardening tendency, would be more useful to the reader if adequate references, by which the subjects could be followed further, had been given. The author evidently expects his students to have access only to the Journal of the Iron and Steel Institute and the Journal of the Institute of Metals. Grossmann and Bain's simplified diagram for high speed is used, but their book is ignored, only a Journal of the Iron and Steel Institute reference being given. Nor is Monypenny's Stainless Iron and Steel referred to.

The book starts with the blast furnace, deals very briefly with cast iron, malleable iron and wrought iron, more fully with the manufacture of steel, then turns to equilibrium diagrams and to the metallography and heat-treatment of steel. Alloy steels are discussed, case hardening commented on fairly fully, nitriding very sketchily. The stainless steels get special attention, then cold working processes are discussed.

Sixty pages are then devoted to the more common non-ferrous alloys, the treatment being very brief, but surprisingly clear and comprehensive for so small a space. The omission of zinc-base die castings leaves out a class of alloys of considerable engineering importance. A brief discussion of welding completes the book.

On the whole, the engineer who has assimilated the contents of this book should have a good start toward an understanding of the how and the why of the manufacture of most important metallurgical materials of construction.
H. W. Gillett (0) -B-

National Directory of Commodity Specifications. C. W. INGELS. *U. S. Bureau of Standards Miscellaneous Publications* No. 130, 1932. Cloth, 8 x 11 inches, 548 pages. Price $1.75.

This is the first revision of the Directory. One section of 88 pages is devoted to ores, metals and manufactures, which include the existing specifications of all such bodies as the A.S.T.M., American Railway Association, S. A. E., Federal Specifications Board, etc., on dimensions, composition or properties. Recommended practices are also included. Other commodities are dealt with in the same way. The volume is thoroughly indexed. Only American specifications are included. H. W. Gillett (0)-B-

PROPERTIES OF FERROUS ALLOYS (3)

Characteristics of Alloyed Cast-Iron. F. W. Shipley. *S. A. E. Journal,* Vol. 30, Mar. 1932, pages 120-128.

Increased quality, which is reflected through higher valve-seat hardness and improved microstructure, can be obtained by additions of Ni and Cr in automobile-cylinder Fe. See *Metals & Alloys,* Vol. 3, May 1932, page MA 118. Ha (3)

New Rustless Iron Alloy. R. P. De Vries (Ludlum Steel Co.). *Metals & Alloys,* Vol. 3, Feb. 1932, pages 49-50.

The author discusses the working, soldering, welding, riveting, pickling, polishing and heat treatment of a new stainless material of 0.10% C, about 16% Cr, about 1% Si, about 1% Cu, about 0.40% Mn and S and P 0.03%. Tensile properties at room and elevated temperatures are tabulated. WLC (3)

Wear of Armatures and How It is Combated. (Verschleiss von Armaturen und seine Bekampfung.) Wahl. *Maschinenkonstruckteur-Betriebstechnik,* Vol. 64, Sept. 10, 1931, pages 191-194.

Wear in armatures is due to corrosion, rubbing and radiation. The effect of alloying and chances for estimating the life of armatures from the properties of its materials are discussed. Coating the metal is advocated to prevent wear. MAB (3)

Relations between the Various Mechanical Properties of Cast Iron Among Themselves and Its Structure. (Relations entre les divers propriétés méchaniques d'une part, les Propriétés méchaniques et la Structure d'autre Part des Fontes de Moulage.) Ch. Baron. *Revue Universelle des Mines,* Series 8, Vol. 5, July 15, 1931, pages 33-35.

The tests made on 17 kinds of cast Fe on the relation of tensile, bending and shearing strength among themselves and to the wall-thickness and chemical composition show that preferably an Fe with a pearlitic structure should be used in order to obtain the best possible elastic limit and resistance to fracture. Bending tests on small specimens are quite sufficient to estimate the quality of a cast-Fe. Ha (3)

The Notch Sensitivity of Cast Iron Stressed by Bending. (Ueber die Kerbempfindlichkeit von Gusseisen bei Beanspruchung auf Biegung.) F. Roetscher. *Maschinenbau,* Vol. 11, Feb. 18, 1932, pages 79-80.

It is shown that cast Fe under bending stresses is sensitive to notches, and the sensitivity increases in proportion to the depth and sharpness of the notches. This is explained by the distribution of stresses in highly stressed cross sections. RFV (3)

Permanent Growth of Gray Cast Iron. W. E. Remmers. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 219-229.

Includes discussion. See *Metals & Alloys,* Vol. 1, Oct. 1930, page 791. (3)

Tool Steels for Dies. (Werkzeugstähle für Schnitte.) F. Rapatz & H. Pollack. *Feinmechanik und Präzision,* Vol. 40, June 1, 1932, pages 101-103.

The selection of a steel suitable for dies should be guided by the following points: (1) shape of the die, (2) capacity required of the die, (3) thickness of the material to cut, (4) nature of the material to be cut. The shape determines whether the die is to be hardened in oil or water; complicated forms are hardened in oil as then less tendency exists for warping or deforming. If thick material is to be cut a tougher steel must be used; the toughness is inversely proportional to the wear resistance; the unalloyed C steels have the greatest toughness but wear most. The composition of some of the most used tool steels is given and their heat treatment briefly described. Ha (3)

Nickel-Iron and other Nickel Alloys with Special Physical Properties. (Nickel-Eisen und andere Nickel-Legierungen mit besonderen physikalischen Eigenschaften.) U. Retzow. *Elektrotechnik und Maschinenbau,* Vol. 50, June 12, 1932, page 349.

On the basis of the diagram of state of pure Ni-Fe alloys 2 groups are distinguished: the irreversible alloys with from 0 to about 30% Ni, with temperature hysteresis of the magnetizability, and the reversible alloys with higher Ni-content. If C is present as alloying constituent, up to 0.5% the border shifts to lower Ni-content and a new group is formed between the 2 first named groups, the alloys of which are not magnetizable at normal temperature. The alloy with 36% Ni shows the highest specific heat but the least heat expansion which combined with very favorable tensile properties makes this alloy very useful for many technical applications especially in the construction of instruments. Fe-Ni alloys are particularly used because of their peculiar magnetic properties, in particular high magnetizability with small magnetizing forces; there is, however, a great dependence on temperature, with increasing temperature the magnetic saturation decreases. The addition of Co tends to produce a more uniform permeability for changes of small electric fields (use in Pupin coils). Alloys from 40 to 50% and with 20% Ni show particularly the phenomenon of magneto-striction which is sometimes utilized for keeping the frequency of oscillating circuits constant. For temperatures below freezing point these properties do not hold good. Here pure ferro-magnetic behavior takes place. Alloys of 35-36% Ni show the maximum of specific resistance, 0.85 ohms/mm.^{2}/m. The thermoelectric property, also with additions of Cr and Mo is used in thermocouples up to about 1000° C. Ha (3)

Some Notes on Blue Brittleness. Leland Russell van Wert. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, pages 230-246.

Includes discussion. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 243. (3)

Lattice Distortion and Hardness of Heat-treated Tungsten Magnet Steels. W. A. Wood. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Ser. 7, Vol. 13, Feb. 1932, pages 355-360.

The specimens were subjected to various heat treatments. Decrease in magnetic quality and hardness on heating to about 900° C. is due to disappearance of lattice distortion. Recovery of these properties at 1250° C. is due to re-introduction of the distortion. RHP (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Resistance of Copper, Tin-Bronzes and Tin Towards Attack by Inorganic Acids. (Zur Kenntnis der Widerstandsfähigkeit von Kupfer, Zinnbronzen und Zinn gegen anorganische Säuren.) W. Claus & H. Fincke. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, pages 64-65; May 1932, pages 112-114.

The attack of Cu-Sn cast alloys, annealed and unannealed, with 3, 6, 10, 14, 20 and 32% Sn, and of pure Sn, by HCl solutions with 3.03, 4.8 and 15.3% HCl, for periods of 8 and 50 hours was studied. The weight losses are expressed in graphs. The second article includes tables and diagrams showing weight loss against time for HCl, H_2SO_4 and H_3PO_4. RFM (4)

Corrosion of Metals by Milk and Its Relation to the Oxidized Flavors of Milk. E. S. Guthrie, C. L. Roadhouse & G. A. Richardson. *Hilgardia,* Vol. 5, Mar. 1931, pages 425-453.

Experiments have been made at the California Agricultural Experimental Station on the behavior of the following metals and alloys in contact with sweet milk: Cu, Ni, Ni-Cu-Zn alloy, Monel metal, Ambrac (Cu 75, Ni 20, Zn 5), brass Ni bronze, Cr-Fe alloys, tin-plated Ni, Al, Cd, and Ni-Cr austenitic steel. Conditions of test included continuous and intermittent immersion, exposure during pasteurization, electrolytic corrosion. The results confirm the outstanding suitability of the Ni-Cr austenitic steels for use in dairy equipment, as they do not produce a metallic flavor. Other materials were not entirely satisfactory as they partly dissolve, or give a flavor. Ha (4)

Corrosion of Metals by Milk. Effects of Operating Conditions on Corrosion in Various Parts of Pasteurizing Equipment. H. A. Trebler, W. A. Wesley & F. L. LaQue. *Industrial & Engineering Chemistry,* Vol. 24, Mar. 1932, pages 339-350; July 1932, page 839.

Presented before the Division of Industrial and Engineering Chemistry at the Buffalo, N. Y. meeting of the American Chemical Society, Sept. 1931. 6 references. It was found that Ni is suitable for equipment used in transportation and storage of milk at ordinary temperatures, heating milk to the pasteurizing temperature and holding it at that temperature, and cooling milk from 18° C. and handling it below that temperature. Ni should not be used in contact with milk cooling in the range from 63° to 18° C. The Cr-Ni alloy containing 12 to 15% Cr is suitable for all types of pasteurizing equipment. Bare Cu and Ni-Ag should be used with caution in the final stages of heating milk and in the initial stages of cooling milk. MEH (4)

Corrosion Prevention Methods in Brine Tanks and Ice Making Tanks. R. S. Wheaton. *Power,* Vol. 75, June 7, 1932, pages 857-858.

H_2O temperature must be below 40° F. before introducing $CaCl_2$ or NaCl, since warm brine is corrosive. 100-125 lbs. of $Na_2Cr_2O_7$/1000 ft.^{3} of brine should be dissolved in the tank; if the brine is made with NaCl, up to 200 lbs. of $Na_2Cr_2O_7$ is necessary. Where cans are leaky and coils thin due to rust, the treatment of brine with $Na_2Cr_2O_7$ will clean off rust to such an extent that leaks will result. Old brines should be thrown away if new cans are to be used. AHE (4)

Abrasion of the Surface of Rolls. (Abnutzung von Walzenmänteln.) *Tonindustriezeitung,* Vol. 56, July 21, 1932, pages 742-743.

A comparison between the wear of chilled rolls and Mn hard steel rolls shows the great superiority of the latter. GN (4)

The Erosion of Steam Turbine Blades. F. W. Gardner. *Engineer,* Vol. 153, Feb. 5, 1932, pages 146-147; Feb. 12, 1932, pages 174-176; Feb. 19, 1932, pages 202-205; *Power,* Vol. 75, Mar. 29, 1932, page 490.

General discussion is given of the nature of blade erosion. Rate of erosion depends upon the following factors: blade material, their velocity, the quantity of water which strikes them, the vacuum in the turbine at the point in question and the percentage of air or other non-condensable gas in the steam. A method of blade protection is outlined in which an independent shield of very hard material is brazed on to the blade. The shield can be removed and renewed easily. Photographs are given showing typical protected and unprotected blades after continued service. Research carried out by the author's firm led to the conclusion that hardness is the most important property in determining the resistance of a material to erosion. Various types of materials were tested including some non-ferrous alloys, C steels, Mn steels, stainless steels, austenitic steels and other Ni-Cr alloys, high-speed tool steels, and steels with special treatment such as Cr plating or nitriding to produce a hard surface layer. Micrographs are given showing typical erosion cavities in austenitic steels and in W steel. The W steels gave the best results of the materials tested. A method is given for estimating the pressures produced on the blade surface by the impact of water drops. AHE+LFM (4)

Prevention of Valve-Seat Erosion. Edward M. Getzoff. *S.A.E. Transactions,* Vol. 26, 1931, pages 361-364.

See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 32. (4)

Corrosion by Cavitation in a Diffusor. (Korrosion durch Kavitation in einem Diffusor.) H. Schroeter. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, May 21, 1932, pages 511-512.

Results of tests with bakelite, Zn and gray Fe made in a pressure pump are described. The corrosive attack seemed to be due more to mechanical than any other reasons. Ha (4)

The Corrosion Problem. III. Aluminum, Lead, Copper. (Zur Korrosionsfrage. III. Aluminium, Blei, Kupfer.) L. W. Haase. *Gas und Wasserfach,* Vol. 75, May 14, 1932, pages 372-374.

Commercial Al is practically unfit for water lines. Al, when used for cooking utensils, is also more or less severely attacked. Pb pipes, tinned or sulphurized Pb pipes and hard Pb pipes are attacked by cold water, when the water is acid and contains free CO_2 but only when O is also present. Effective protective layers are formed only in water rich in $CaCO_3$ and containing O, provided an increased content of H_2S, humus substances, chlorides, nitrates and sulphates does not counteract the formation of such layers. With few exceptions Cu resists the attack of cold, salty and hot water. GN (4)

Topochemistry of Corrosion and Passivity III. (Zur Topochemie der Korrosion und Passivität III.) E. Pietsch, E. Josephy, B. Grosse-Eggebrecht & W. Roman. *Korrosion und Metallschutz,* Vol. 8, Mar. 1932, pages 57-66.

The authors point out that the local elements occurring during corrosion cannot be checked experimentally and differ fundamentally from those "model elements" consisting of 2 different short circuited metal electrodes in an electrolyte, on account of their bi-dimensional phase boundaries. Based on the results in contact catalysis, the writers assume in the theoretical part of the paper that the primary effect of the corrosion phenomenon and of the heterogeneous catalysis is identical, i.e. an adsorption of the corroding reagent takes place at "energetically preferred surface potentials," mainly at crystal edges and corners of individual crystals, at grain boundaries of poly-crystalline material and at inhomogeneities of otherwise homogeneous surfaces, caused by disturbances during crystal growth or by mechanical stress, or at heterogeneous phase boundaries as for instance: Zn/Pt. If there is an opportunity of compensating free charges, 2 effects will occur (A) a compound is formed with the aid of the solid body of surrounding lattice particles (formation of adherent rust or of $ZnSO_4$) and (B) "recombining" and separation from the surface due to the lower adsorption potential as for instance in case of H_2. The experimental part of the publication refers to an investigation on soft Fe on which the correlation of the grain boundaries to the primary corrosion effect at homogeneous surfaces was systematically studied. The difficult pre-treatment is described and a linear dependence of the dissolution process on the total length of grain boundaries was established. The paper includes 45 references. EF (4)

Optical Investigations into the Passivity of Metals. I. Iron and Steel. (Optische Untersuchungen zur Frage der Passivität der Metalle. I. Eisen und Stahl.) L. Tronstad. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 158, Feb. 1932, pages 369-397.

Optical measurements previously made on electro-chemically activated and passified Fe and Ni mirrors (*Nature,* Vol. 142, 1929, page 373) were extended to the following Fe and steel samples: 0.04% C steel, 0.4% C steel, Flodin Fe with 0.01% C, pearlitic steel with 0.82% C and 1.3% C steel, Cr-Ni steel with 0.15% C, 0.54% Cr and 3.1% Ni, stainless steel, Cr-steel with 0.08% C and 14% Cr, and "18/8" with 0.07% C, 18% Cr and 7.4% Ni. The testing solutions were alkaline, neutral and acid. The present investigation also includes single potential measurements and more attention was paid to securing a surface absolutely free from a film. On the first passification, optical changes always occurred on homogeneous and heterogeneous mirrors. By means of Drude's equation, the changes were ascertained as being due to a film of 30 A. U. thickness with a reactive index of 3.0. Since this diffraction index largely coincides with that of an oxide, it is highly indicative that the phenomenon of passivity is closely connected with the formation of an oxide film (oxide film theory). The films occurring during the passification treatment could be removed to a more or less complete extent (depending on the solution and kind of steel) by an activation treatment. However, porous oxidic layers (rust) occasionally appeared due to a continuous activation and passification. With reference to the heterogeneity of the highly polished samples, higher current densities were required to produce passivity under otherwise equivalent testing conditions. On heterogeneous mirrors the optical changes produced by passification became reversible to a smaller extent as was the case with homogeneous specimens. The oxide film remained on cementite and double carbide grains. EF (4)

British Report on Deterioration of Marine Structures. *Engineering News-Record,* Vol. 109, July 7, 1932, page 19.

Investigation by committee of British Institution of Civil Engineers on the deterioration of lumber, concrete and metal structures in sea water has been in progress since 1916. Fe and steel specimens were under exposure for 10 and 15 years at Auckland, Halifax, and Plymouth. The 36% Ni steel aerial bars appear in all cases to be in perfect condition, and the aerial bars of 13½% Cr steel appear to be corroded appreciably less than the rest of the metals exposed to air. Specimens placed at half-tide level are generally covered with marine growths, but they reveal differences according to the port of exposure; at Auckland all bars show spots through the barnacles. At Halifax the 13½% Cr steel is in good condition save for pitting at one end, and the Swedish Fe and hot-blast cast Fe appear to be well preserved, while the 36 and 3½% Ni steel and the Armco and Low Moor irons are in fairly good condition. The half-tide bars at Plymouth are heavily incrusted with barnacles, the 2 Ni steels appear to have deteriorated less seriously than the rest. The entirely immersed bars at Auckland are all thickly covered with growths, and rust is appearing on all, but least on the Ni steel and 2 of the wrought irons. The bars immersed at Halifax and Plymouth are also for the most part rusty and covered with marine growth, but the original surface can be seen on the high Ni and Cr steels. CBJ (4)

Corrosion Resisting Nickel Cast Irons. (Les fontes au nickel resistant a la corrosion.) *Revue du Nickel,* Vol. 3, Jan. 1932, pages 21-28.

Ni graphitizes cast irons. With more than 12% Ni cast irons become austenitic and graphitic. The corrosion resistance of such cast irons is of the same order as that of stainless steels. For best properties 3% C is preferable. Addition of small amounts of Cu to austenitic Ni cast irons increases the corrosion resistance in H_2SO_4. Small amounts of Cr are beneficial. Such cast irons are actually in use in the artificial silk industry for parts of machinery that come in contact with H_2SO_4. They are also used in the petroleum and mining industry on account of their low cost and excellent corrosion resistance at high temperatures. AH (4)

Eloxal, the New Corrosion Protection Technique for Aluminum. (Eloxal, die neue Korrosionsschutztechnik für Aluminium.) *Werft, Reederei und Hafen,* Vol. 13, Mar. 1932, page 76.

Calls attention to the new anodic oxidation of Al, designated as Eloxal, and urges adoption of eloxalized Al in ship building. EF (4)

ILLIUM is not a "new" alloy. It has been in successful use more than 15 years, sometimes in acids—sulphuric, nitric, acetic, phosphoric, *mixed* nitric and sulphuric, etc.—sometimes in alkalies.

While not a cure-all for every ill, ILLIUM *is* a complete, permanent and moderate priced answer to many of the corrosion troubles commonly encountered.

Dense, close grained, with considerable tensile strength, ILLIUM withstands heat, torque, impact and wear. It is especially recommended for pump and valve parts, agitators, or pieces requiring accurate machining.

UNIVERSAL
CORROSION-RESISTANT
ALLOY
sold in form of castings, easily machined, takes high polish

ILLIUM castings, rough or finished are made to your specifications in our modern foundry. Our engineers will quote from your patterns or drawings, or will work with you in designing ILLIUM parts for your product.

MOLINE, ILLINOIS

"Had we only known about Durimet two years ago,"

said the man in charge, "we could have saved thousands of dollars."

Those were his exact words.

We can't tell you the name of the company as their policy won't permit it, but you would know who they are—well-known, national advertisers.

They use Durimet for soldering-jig parts that are exposed to acid and heat corrosion. The original installation—made several months ago—is still as good as when put in. And previously they had to change these same parts every two or three weeks, depending upon the production schedule.

Durimet has many other advantages that you ought to know about—the many, many acids it handles satisfactorily . . . the low carbon content (max. .07%) that defeats that insidious undercover worker, intercrystalline corrosion . . . its remarkable resistance to sulphuric acid at the lower concentrations at all temperatures, and especially to pickling solutions containing iron salts . . . its machining and welding properties.

In selecting an alloy steel for corrosion resistance, it isn't a matter of personal preference or superficial tests—unless you have a lot of money to spend. Selecting the right alloy steel for the job is one of the best "grief-savers" known.

See that coupon down there? Clip it and send it in. To help us help you, include under conditions: solutions used, concentrations, temperatures and pressures. And if you wish, one of our sales representatives will be glad to call and give you further information, without obligation.

Patina. (Patina.) CARL RANCKE. *Oberflächentechnik*, Vol. 9, June 7, 1932, pages 111-113.

The natural corrosion of Cu and bronze articles with its artistic effects is discussed and a few methods described to obtain the same effects by artificial means, especially electrolytic treatments. Ha (4)

1

The Open-Air Corrosion of Copper. Part III.—Artificial Production of Green Patina. W. H. J. VERNON. *Institute of Metals, Advance Copy* No. 619, Sept. 1932, 9 pages.

Artificial coatings produced by chlorides were not stable when exposed to the atmosphere. A basic-sulphate patina can be produced by the action of a 10% solution of $(NH_4)_2SO_4$. In this method the solution is applied twice daily for about 6 days. It is then washed with a 10% solution of $CuSO_4$ containing 1% NaOH and 5% NH_4NO_3. Such a coating begins to peel away during the first period of frost. A stable patina

2 can be produced electrolytically by making the Cu anode in a suitable electrolyte. A good electrolyte contains 10% $MgSO_4$, 2% $Mg(OH)_2$ and 2% $KBrO_3$. The bath is operated at 95° C. The optimum current density is 4 amp./dm.^{2} with the electrodes 1.5" apart. The treatment is continued for about 15 min. After washing in water the material is ready for service. Exposure tests proved that the patina was stable even under freezing conditions. When formed the coating corresponds to $CuSO_4 \cdot Cu(OH)_2$. Its basicity increases on exposure. Definitely better results were obtained with arsenical Cu, and a material containing 0.45% As was used in the main experiments. Sn(0.8%) and Ni(2.5%) caused inferior coatings.

3 Good patinas were formed on statuary bronze by the electrolytic method. JLG (4)

Corrosion Resistant Lead. (Korrosionsbeständiges Blei.) *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, July 10, 1932, page 367.

Experiments of the German Dye Trust show that the resistance of Pb to certain chemical attack can be considerably increased by the formation of passive layers. The best effect is obtained when the element added is present not as a eutectic but as a mechanical admixture. By hammering or rolling Ag fillings into the Pb surface, Pb becomes absolutely stable against the attack of hot concentrated H_2SO_4.

4 By alloying Ag to Pb the poor resistivity of pure Pb against hot H_2SO_4 is not improved. GN (4)

Note on the Reaction between Hydrogen Sulfide and Mercury. ARTHUR L. ROBERTS. *Journal American Chemical Society*, Vol. 53, May 1931, pages 1810-1811.

It was found that Hg is immune from attack by H_2S free from air and moisture. MEH (4)

The Effect of Supports on the Catalytic Activity of Nickel. CHARLES R. GLASS & LOUIS KAHLENBERG. *Transactions Electrochemical Society*, Vol. 59, 1931, pages 135-156.

5 Includes discussion. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 163. (4)

Silver Alloys of High Corrosion Resistance. (Schweranlaufende Silberlegierungen.) *Deutsche Goldschmiedezeitung*, Vol. 35, Jan. 16, 1932, pages 24-25.

The paper first refers to investigations by Fischbeck in which the resistivity of a large number of Ag alloys was tested in a saturated solution of S in aniline. The 800-835/000 Ag alloys with Zn and Cd have the highest resistance to tarnishing (attack of S). However, these alloys are rather

6 soft. Experiments on improving the mechanical properties by age hardening components are discussed. GN (4)

Two Years' Corrosion Tests with Duralplat in the North Sea. K. L. MEISSNER. *Institute of Metals, Advance Copy* No. 613, Sept. 1932, 11 pages.

Duralplat comprises an alloy equivalent to 17S coated with an Al-rich Al-Mg-Mn alloy more resistant to corrosion than the base alloy. Its strength when properly heat treated is equivalent to that of Duralumin or 17S. Samples of sheets, shapes and riveted structures were exposed. Some were always immersed and some were exposed at ebb and

7 flow tide. Corrosion was estimated from loss in weight, tensile properties and microscopic examination. Attack of the base metal was observed only in the thinnest sheet (0.5 mm.). It was concluded that "Two years' corrosion tests with Duralplat in the North Sea showed the excellent corrosion resistance of the material," and "The life of thicker materials, especially more than 1 mm., is undoubtedly very long. Due to loss of specimens in a storm, tests on the riveted materials extended only over 18 months. The rivets corresponded to the composition of the base material. No rivets were loosened by corrosion. JLG (4)

8 **Determination of Corrosion of Iron, Chromium and Nickel and Corrosion and Heat-Resistant Alloys of These and Other Metals. (Korrosionsbestimmungen an Eisen, Chrom und Nickel, sowie an korrosions- und hitzebeständigen Legierungen dieser und anderer Metalle.)** R. MUELLER, G. HAHN & H. KRAINER. *Berg- und Hüttenmännisches Jahrbuch*, Vol. 80, June 10, 1932, pages 74-78.

The electrolysis of melts of fluorides requires heat- and corrosion-resisting materials. The experiments with Fe, Cr and Ni and various alloys showed that in a melt of MgF_2 at 950° C., Fe was the least and Ni the most resisting, with

9 Cr in between; after 6 hours test Fe showed an average loss of 10.3%, Cr, 9.3%, and Ni a very slight increase in weight, due very likely to a thin film formed on the surface. Cr-C steels show at first with increasing C content a deterioration; with higher C content near the eutectic point an improvement takes place. Ni steels show with increasing Ni content an increase in corrosion resistance. Si has a slight improving influence. Cr and Ni increase the resistance considerably, particularly steel with 19% Cr and 40% Ni showed the best values next to pure Ni. An addition of Al seems also to have a favorable effect, the same is true

10 for Mo and Cu; but the replacement of Ni by Co leads to strong corrosion. In general, it could be stated that, under the influence of molten $Mg-F_2$, pure Ni is the most resistant, highly alloyed Cr-Ni steels are a close second, while the typical heat-resisting C-Si steels are comparatively strongly attacked. The actual loss in material for all tests is tabulated. Ha (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Micrography (5a)

The Microstructure of Hardened Carbon Steel. H. E. Publow & Fitz Randolph. *Michigan State College, Engineering Experiment Station Bulletin* No. 45, Vol. 7, Apr. 1932, pages 1-19.

1 The theory of Sauveur of the transformation of austenite into martensite is accepted as giving the best explanation, but numerous tests and examinations of structures made at different points along the heating curve and quenching at different temperatures showed discrepancies as sometimes exactly the same structures had absolutely different physical properties and behaved quite differently in their reaction toward etching reagents. It is assumed that there is a chemical as well as a purely physical change that takes place within the critical range of heating which has a bearing upon the hardening properties of the Fe-C alloys. Thermal points in equilibrium diagrams do not always indicate reformation of grains but rather an evolution or absorption of heat which means either a chemical change or a recrystallization or both. If a chemical change takes place it may occur within the C molecule and there may also be a change in the relations existing between C and Fe. The fact that steels which have been quenched at various temperatures within the critical range show pronounced differences in their reaction toward HNO_3 would tend to corroborate the assumption of a chemical change. The Solubility of Gold in Mercury. III. Arthur A. Sunier & Law G. Weiner. *Journal American Chemical Society,* Vol. 53, May 1931, pages 1714-1721.

5 About 50 determinations of the solubility of Au in Hg have been made in the temperature interval 200° to 300° C. with a modified solubility tube and an air-bath. No maximum in the solubility curve is found, the results being confirmed by 6 supplementary runs using the synthetic method. MEH (5a)

The Causes of the Transformation of Austenite into Martensite in the proximity of Room Temperature. (Ueber die Ursache der Umwandlung des Austenit in Martensit in der Nähe der Raumtemperatur.) Erich Scheil. *Zeitschrift für Elektrochemie,* Vol. 38, July 1932, pages 554-557.

1 The thermal exchange of places of the atoms to which in most cases the transformation of phases of materials can be ascribed does not explain transformations in polymorphous types of crystals. This is investigated particularly for the transformation of austenite into martensite for which the reason is seen in a stress in the direction of deformation. The influence of the stresses and the grain sizes and grain borders on the transformation is discussed on the basis of experiments. Ha (5a)

Transformational Characteristics of Iron-manganese Alloys. Howard Scott. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 284-306.

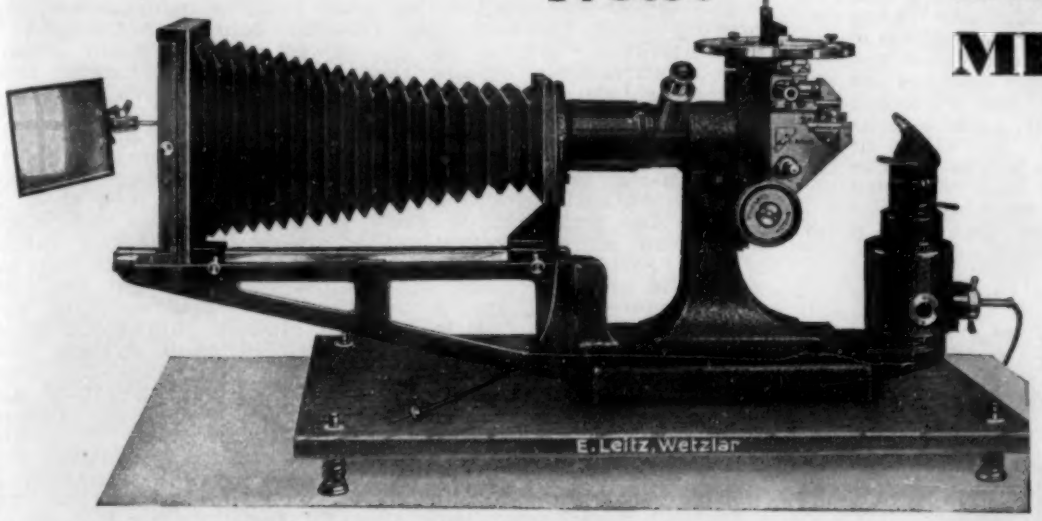
The Constitution of the Lead-Tin Alloys. D. Stockdale. *Institute of Metals, Advance Copy* No. 617, Sept. 1932, 16 pages.



3 A microscopic method, 2 thermal methods, and an electrical resistance method were used in determining the solid solubility of Sn in Pb. Other portions of the diagram were studied, but not so elaborately. The solid solubility of Sn in Pb was found to be 19.5% at the eutectic temperature. It fell to 2% or less at room temperatures. No definite conclusion was reached regarding the evolution of heat at 150° C., but it is improbable that it is an allotropic transformation. JLG (5a)

The Transformations of Cobalt, Nickel and Iron. (Ueber die Umwandlungen von Kobalt, Nickel und Eisen.) Alfred Schulze. *Die Giesserei,* Vol. 19, May 13, 1932, pages 187-189; June 10, 1932, pages 226-230.

4 The transformation of metals is defined as a transition from one modification into another and by a change of properties in spite of the same chemical composition. The transformation is usually connected with a change of the lattice structure which means an allotropic modification. Besides these, there exist 2 transformations closely connected with the magnetic behavior of the metal; these points are called the Curie points; here the ferromagnetic metal loses its ferromagnetism. These transformations were investigated for Co, Ni and Fe. The experiments are described in detail and the changes in the physical properties at the transformation points discussed. Co has an allotropic transformation between 400° and 500° C. and a magnetic transformation at 1128° C., Ni a magnetic transformation at 356° C., Fe a magnetic transformation at 768° C. and 2 allotropic transformations at 906° and 1401° C. The electric

5 resistance and thermoelectric force, thermal expansion, specific heat and heat conductivity show clearly these modifications at the respective points; the behavior at the magnetic transformation points, however, differs from that at the allotropic transformation points. Ha (5a)

New!

LEITZ MICRO-METALLOGRAPH

Simplified Model "MM-2"

Note: The Leitz Darkfield Equipment and the new series of Leitz Objectives (corrected for infinity) are supplied with the Simplified Micro-Metallograph "MM-2."

The Inverted Microscope and Camera of Micro-Metallograph Simplified Model "MM-2" represent a modified as well as simplified construction of the well known Leitz Micro-Metallograph Large Model "MM-1" which is so successfully used for micro-analysis of metals. The purpose of offering the Simplified Model "MM-2" is *to provide at the lowest possible cost an instrument including all essential equipment both in optical and mechanical respects that meets the entire range of practical requirements from carbon-iron alloys to metals of every variety.*

The New Instrument fulfills a demand which has hitherto existed for micro-metallographic equipment arranged in its construction to meet the efficiency known to exist with the large Micro-Metallograph, however, in price so arranged, that industrial and educational laboratories with a moderate purchasing budget can be accommodated.

The Penetration of Filtered Heterogeneous X-rays through Copper, Aluminum and Lead, Determined by Use of Photographic Methods. (Die Durchlässigkeit von Kupfer, Aluminium und Blei für gefilterte heterogene Röntgenstrahlen ermittelt unter Benutzung der photographischen Indikation.) MAX WIDEMANN. *Metallwirtschaft,* Vol. 11, July 8, 1932, pages 383-386.

The penetration of X-rays through metals depends on the atomic number, density and thickness of the metal, and on the shortest wave length of the X-ray spectrum. The formulas showing these relationships are developed. From numerous tests on Cu, Al and Pb the values for b = milliamp-sec. necessary to produce a .7 blackening effect on the photographic film for various thicknesses of metal and using from 60 to 200 kv. were determined. These values are plotted in the form of graphs. A blackening effect of .7 was chosen because in this range a contrast as small as .005 can be detected by the eye in diffused daylight. If the object being examined is of very irregular shape 2 or more radiographs should be taken with b values corresponding to the various thicknesses. It is better to overexpose than to underexpose. Knowledge of the b values can be used for the choice of the best suited exposure time for a radiograph, for the determination of the smallest discernible difference in thickness, for the comparison of the efficiency of 2 X-ray tubes and for the determination of the rate of penetration. 7 references. Is there a Compound Al_2Zn_3? (Gibt es eine Verbindung Al_2Zn_3?) M. v. SCHWARZ & O. SUMMA. *Metallwirtschaft,* Vol. 11, July 1, 1932, pages 369-371.

Other investigators using micrographic and thermo-analytical methods have claimed that the compound Al_2Zn_3 containing 21.3% Al and 78.7% Zn exists. However, the reported concentration and temperature zones differ. The authors found that alloys containing 10 to 50% Al with and without small Mg and Cd additions have a definite arrest in their heating curves at 290°C. The cooling curves indicate the decomposition of β into γ and α phases. A wire containing 21.3% Al, .1% Mg and 78.6% Zn was examined by X-rays. The Debye diagram indicated a hexagonal arrangement similar to pure Zn, but the strongest Al lines were also visible. When heated to 350°C. for 60 min. and quenched in ice water the wire had a face centred cubic lattice with a 3.978 A.U. lattice constant, while that of pure Al is 4.043 A.U. An alloy of 25% Zn and 75% Al, which is beyond the limits of the γ solid solution, heat treated the same way had a lattice constant of 4.030 A.U., and a 50% Zn alloy had almost the same constant. The constants of the phase and the β solid solution can easily be distinguished. After aging the quenched 21.3% Al alloy at room temperature it gradually assumes a hexagonal arrangement while the intensity of the cubic lattice becomes less. This change is hastened by heating up to 350°C. and cooling slowly. The β phase decomposes. Calculating from the specific weight, the molecular weight and the lattice constant the compound Al_2Zn_3 would have .79 molecules per lattice cell, which deviates considerably from a whole number. Assuming a substitution solid solution the result is 3.96 or practically 4. The authors conclude that there are 2 electron arrangements. In one the valence electron is attached to the nucleus and the atom becomes elliptical and leans toward an hexagonal arrangement. In the other the valence electron is loosely connected with the nucleus, the atom is spherical and leans toward a cubic arrangement. The proportion of the 2 kinds of electron arrangements depends on the temperature and the development of the hexagonal or the cubic symmetry takes time. This also explains the great instability of the β phase at low temperatures. 12 references. CEM (5b)

Poly-plumbites, Poly-stannides and their Transition into Metal Phases. II. Communication on Metals and Alloys. (Polyplumbide, Polystannide und ihr Uebergang in Metallphasen. II. Mitteilung über Metalle und Legierungen.) E. ZINTL & A. HARDER. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 154, Jan. 1931, pages 47-91.

In the otherwise purely chemical research work on poly-plumbides and poly-stannides, the binary system Na-Pb is investigated by X-rays between 0 and 50 atomic % Na. Three phases α, β and γ occur. The space lattice constant of Pb was found to be 4.943 A.U. An alloy with 2.2 atomic % Na yielded the diagram of pure Pb with slightly enlarged glancing angles indicating a space lattice contraction during the formation of a solid solution of Pb with Na. The parameter of the α phase, which is saturated with Na at a concentration of 15.3 atomic %, amounts to 4.932 A.U. The space lattice contraction phenomenon is considered to be closely connected with the hardening effect of alkalies and alkaline earth metals on Pb. There are 4 atoms in the cubic elementary cell of the β phase. The cube length is 4.873 A.U. In contradiction to C. A. Mathewson, the investigators deny the existence of an intermetallic compound in the β range of homogeneity. The first lines of the γ phase appear at a concentration of 34.9 atomic % Na. EF (5b)

The Atomic Structure of NaTl and its Relationship to Structures of the Beta Brass Type. IV Communication on Metals and Alloys. (Über den Gitterbau von NaTl und seine Beziehungen zu den Strukturen vom Typus des beta-Messings. 4. Mitteilung über Metalle und Legierungen.) E. ZINTL & W. DULLENKOPF. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 16, Mar. 1932, pages 195-205.

Powder photograms of NaTl revealed a cubic atomic arrangement with a = 7.473 A.U. and 8 atoms of Na and Tl to the elementary body. The radius of Tl in NaTl is 1.62 A.U. which is in agreement with Goldschmidt's findings. The Na atoms in NaTl are 13% smaller than in the pure element Na. In structural regard, NaCl is related to the body centered alloy phases of the β brass type. The influence of polarization, of the ratio of sizes of the atoms, and of the average number of valence electrons per atom on the manner of distribution of 2 kinds of atoms in a lattice arrangement is discussed. The law of Hume-Rothery-Westgren & Phragmén correlating the structural type to the average number of valence electrons per atom does not hold true for alloys containing very base metals. EF (5b)

Includes discussion. See *Metals & Alloys,* Vol. 1, Dec. 1930, page 908. (5b)

The Lattice Constants of Silver-Palladium and Gold-Palladium Alloys (Die Gitter Konstanten der Silber-Palladium und Gold-Palladium legierungen.) W. STENZEL & J. WEERTS. Festschrift zum Fünfzigjährigen Bestehen der Platinschmetze (1881-1931). G. Siebert, G. m. b. H. Publisher, G. M. Alberti's Hofbuchhandlung, Hanau. Pages 288-299.

The work was planned to give further information concerning such relations as: specific volume to weight % concentration; lattice parameter to volume % or atomic % concentration; atomic radii to lattice parameter, etc., of solid solutions of alloys. The results of previous studies on these relations are reviewed. To test Vegard's principle that the parameters of solid solutions are additive functions of the atomic % concentrations, alloys of Ag-Pd and Au-Pd were studied—by precision X-ray methods. The interatomic distance in Pd like Pt is less than in Au or Ag, but greater than in Cu. Previous investigations had shown considerable contraction in the lattice of the solid solutions of both Ag-Pd and Au-Pd, but when the more recently determined constants for the pure metals were used the deviations were less certain; also the method employed in earlier studies might be questioned. The authors studied alloys in each system containing approximately 5, 20, 50, 80, and 95% Pd. The specimens used for the X-ray tests with a simplified and improved equipment were 0.4 mm. thick and 1 cm. square. Specimens of each composition were annealed in 4 different ways: (1) annealed in high vacuum; (2) reduced 50% by rolling and annealed in pure argon; (3) annealed in air, and (4) annealed in argon. The annealing time was 1 hr. and the temperature 920 and 1000° C. for the Ag-Pd and Au-Pd alloys respectively. The lattice constants used for Ag and Au, 4.077 and 4.070 A.U., were those previously determined by Sachs and Weerts, while the value for Pd was redetermined as 3.8809, which was in rather good agreement with 3.879 previously reported by Bredig and Allalio. No consistent relation was found between the heat treatments and the resulting parameters, and the values plotted are averages of 4 or 5 determinations. For the Au-Pd alloys the lattice constant varied practically as a linear function of the atomic % concentration. For the Ag-Pd alloys a slight contraction was found, which for the 50 atomic % alloy amounted to about .007 A. U., or about 0.2%. OEH (5b)

Solid Cadmium Amalgams An X-Ray Proof of the Compound Cd_3Hg. NELSON W. TAYLOR. *Journal American Chemical Society,* Vol. 54, July 1932, pages 2713-2720.

X-ray examination of solid Cd amalgams, which had been annealed in vacuo at 147° for 72 hours, has demonstrated the existence of a new crystal phase, body-centered tetragonal. The composition range includes 70 and 75 atomic % Cd, and may be slightly wider. It may be regarded as Cd_3Hg or as a solid solution of Hg in Cd_3Hg. MEH (5b)

X-Ray Examination of Airplane Parts. (Röntgenuntersuchungen von Flugzeugbauteilen bei der Deutschen Versuchsanstalt für Luftfahrt.) KURT MATTHAES. *Zeitschrift für Flugwesen und Motorluftschiffahrt,* Vol. 23, July 28, 1932, pages 459-464.

The paper first describes the X-ray equipment installed at the Deutsche Versuchsanstalt für Luftfahrt 2 years ago. The result of practical tests on cast and welded airplane parts are then reported. Among others spot welded parts of Al alloys and Cr-Ni steel were examined. The examples show that X-rays are most suitable for examining cast and welded finished airplane parts. GN (5b)

X-Ray Examination of Large Chemical Equipment. (Röntgenuntersuchungen an chemischen Grossapparaturen.) W. BUSSE. *Die Chemische Fabrik,* June 1, 1932, pages 185-188.

In the examination of metals, particularly castings and welded metals, for porosity or other defects by the X-ray method, the voltage used should not be greater than necessary for the rays to penetrate in the required time. Otherwise the contrast will be reduced. Tables are given showing the required voltage for various lengths of exposure and various thicknesses of Fe, Al and Cu. The efficiency of detecting defects decreases as the thickness of the metal being examined increases and varies with different metals. The principles of the X-ray diffraction method are explained, including the Debye-Scherrer method. It is useful for the identification of small samples, the examination of structure changes and the study of crystal structure and orientation. CEM (5b)

Convergence Patterns as a Method for Making Layer Line Diagrams in a short Time. (Konvergenzaufnahmen als Verfahren zur Herstellung von Schichtliniendiagramen in besonders kurzer Zeit.) O. KRATKY. *Zeitschrift für Kristallographie,* Vol. 82, No. 1/2, 1932, pages 152-154.

For taking layer line diagrams on macroscopic crystals a camera was constructed which gives patterns in ⅓-⅛ of the time that is necessary in using the common revolving-crystal method. It is essential to use a pencil of X-rays which possesses a large convergence in the plane vertical to the translation period to be determined. During the exposure the crystal is fixed but rotated around the camera axis during that time 1-3 times. GN (5b)

The Relation between Deformation Structure and Recrystallization Structure of Aluminum. (Über den Zusammenhang zwischen Deformations-und Bearbeitungs-Rekristallisationstextur bei Aluminium.) W. G. BURGERS. *Metallwirtschaft,* Vol. 11, Apr. 29, 1932, pages 251-255; May 6, 1932, pages 265-267.

20 references. A cylindrical disk was carefully turned from an Al single crystal and was compressed in many steps, each with a smaller increase in pressure. Laué photographs were taken before and after deformation, also after recrystallizing by heating to 600° C. for several seconds, and pole figures were constructed. It was found that the orientation of the crystallites during recrystallization results from theoretical position of the crystal before annealing by turning about an axis perpendicular to the direction of slip. Only those lattice sections near the ends of the local slip planes which are deflected the most are suitable for the formation of nuclei. The relation between deformation structure and recrystallization structure of single or coarse crystals compressed irregularly is similar to that of those compressed homogeneously. In finely crystalline Al the conditions are different and the deformation and recrystallization structures are identical. All crystallites are equally stressed during compression and are equally suitable for the formation of nuclei during recrystallization. In some cases the recrystallization structure is more distinct than the deformation structure. CEM (5b)

Principles of Material Testing with Gamma-Rays. (Grundlagen der Werkstoffprüfung mit Gammastrahlen.) R. BERTHOLD & N. RIEHL. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 76, Apr. 23, 1932, pages 401-406.

The possibilities of using the γ-radiation of radio-active elements for the testing of materials instead of X-rays are described; while the latter have a wave length of 1×10^{-7} to 5×10^{-10}, γ-rays have a wave length of 5×10^{-10} to 5×10^{-11}. The different sources of γ-radiations are described and, as a practical material, mesothorium can be used instead of the more expensive radium. The half-time value of Ra is 1700 years, that of mesothorium 26 years. The method of application of the preparations are explained; the tests permitted drawing the following conclusions: X-rays are at present suitable only for the irradiation of great thicknesses (steel of more than 50 mm. thick); the small radio-active preparations can easily and conveniently be placed even in fairly inaccessible parts; practically no supervision is required during exposure; the times of exposure are considerably longer for the testing of small or medium thickness (less than 100 mm.) than with X-rays of about 200 kv.; defects are less clearly seen than with X-rays, and luminescent screens cannot be used due to the low intensity of the radiation. As an example, with a mesothorium preparation of 30 mg. (value about 5000 Mk.) a steel of 150 mm. thickness could be photographed at 50 cm. distance from the plate in 40 hours, 100 mm. in 25 hours. Application of X-rays in the Manufacture of Telephone Apparatus. M. BABYERTZ. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 162-175.

Includes discussion. See *Metals & Alloys,* Vol. 1, Dec. 1930. page 907. (5b)

Laws between alpha- and beta-Decomposition Constants (Über Regelmässigkeiten zwischen alpha-und beta-Zerfallskonstanten.) J. KUDAR. *Die Naturwissenschaften,* Vol. 20, Jan. 1, 1932, pages 84-85.

The author confirms that in decomposing radio-active series, 2 successive β transformations and the following or preceding α transformation can be considered as a periodical phenomenon. The laws governing these triadic cycles are given with reference to the uranium, thorium and actinium series. Their life times are computed yielding a value which is practically constant in spite of the considerable fluctuations of the individual τ values. EF (5b)

IF FLAWS ARE CONCEALED THE X-RAY WILL REVEAL THEM

THE manner in which the x-ray is utilized varies in different industries. Most boiler manufacturers radiograph all welded seams as routine procedure. An aluminum foundry reports that it is employed "both in determining the foundry technique which will give the most satisfactory casting and as a production check in order to maintain the original standards." Wire drawing and rolling mills use it to analyze, by means of diffraction patterns, the effect of various treatments on materials.

Nine years ago the General Electric X-Ray Corporation established a special department for the study of the industrial application of the x-ray and to develop apparatus and methods which would adequately meet the increasing requirements for the examination of fabricated materials. This Industrial X-Ray Department is continually devising and installing specialized apparatus for the examination of welds, castings, rolled and drawn metals, hidden assemblies—in fact, for every industrial product in which invisible defects present a problem.

Are you interested in this use of the X-Ray? If so, we will be pleased to send you the latest literature on the subject.

Effect of Illumination on Value of Brinell Ball Indentation. (Einfluss der Beleuchtung bei Ausmessung von Brinell-Kugeleindrücken.) HANS ESSER & HEINZ CORNELIUS. *Stahl und Eisen,* Vol. 52, May 1932, pages 495-496.

In examination of Brinell hardness of electrolytic Cu, electrolytic Fe, and austenitic steel, it was observed that the direction of illumination on the ball indentation could give varying diameter and consequently different Brinell hardness. Deviations in results between lighting perpendicular, inclined and parallel or dark to testing point, amounted to approximately -6.5%. For accurate measurement of ball indentation diameter a dark background is the most suitable. This agrees with work of H. O'Neill, who detected variations of from -6 to -9% with vertical illumination. DTR (6)

Investigations of Weld Seams with the Filings Testing Method. (Untersuchungen von Schweissnähten mit dem Feilspäneprüfverfahren.) EBEL & STEPF. *Zeitschrift des bayerischen Revisionsvereins,* Vol. 36, June 15, 1932, pages 125-127.

The investigations were carried out on the weld seams of 2 boiler drums. The seam is dusted with filings and magnetized. A uniform saturation of the part to be tested with the magnetic flux is of importance for the result. Unless this is guaranteed no reliable conclusions are to be drawn on the quality of the seam. The results to date indicate that the method, when further improved, will become a useful tool for testing weld seams, at least water gas welds. It was shown that failures near the surface can be detected with greatest reliability. Indications are that also internal defects will be detected when very fine file dust is used. GN (6)

Confused Definitions in Material Testing. (Unklare Begriffsfestlegung bei der Werkstoff-Beurteilung.) H. HORNAUER. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 8, Aug. 10, 1932, page 89.

The paper discusses the definition of toughness and brittleness and the Austrian and Swiss proposals for accurate definition. GN (6)

Remarks on the New Theory of Buckling. (Bemerkungen zur neuen Knicktheorie.) F. HARTMANN. *Zeitschrift des Österreichischen Ingenieur- und Architektenvereins,* Vol. 84, Apr. 8, 1932, pages 68-69.

On the Effect of "Self-aid" of Structural Steel in Frame-like Girders. (Über die Auswirkung der "Selbsthilfe" des Baustahls in rahmenartigen Stabwerken.) KARL GIRKMANN. *Stahlbau,* Vol. 5, Aug. 5, 1932, pages 121-127.

The capacity of plastic deformation of a steel and its effects on girders that are subjected to bending and normal stresses is investigated. A method for dimensioning frame-like girder constructions is developed. The results of practical tests are discussed. 5 references. GN (6)

Progress in the Field of Optical Stress Investigation of Structures. (Fortschritte auf dem Gebiet der spannungsoptischen Untersuchung von Konstruktionen.) LUDWIG FOEPPL. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, May 21, 1932, pages 505-508.

The principles of the optical investigation of tensile stresses are explained using the equipment of the laboratory at the Munich University and the different methods of use discussed when experimenting with different materials; flint glass, celluloid, bakelite and phenolite are most frequently used; the latter 2 however offer the drawback of having interior stresses while glass does not. The application to metals of results found in testing such material is permissible as the values of the elastic constants and the Poisson constant are without influence on the state of stress. Exceptions are discussed. 13 references. Ha (6)

Hardness Changed by Magnetism. E. G. HERBERT. *Metal Progress,* Vol. 21, Apr. 1932, pages 52-56.

The author describes research showing that the rotation of hardened steel in an electromagnetic field produces orderly fluctuations in hardness during a 24 hour period subsequent to the treatment. As an example a specimen of 18% W steel 650 Brinell hard was treated electromagnetically at 610° F. and aged at 70° F. reached a minimum hardness of 575 Brinell 3 hours and 30 minutes later and attained a maximum of 725 Brinell at 14 hours. Similar variations were observed in duralumin. From a series of such investigations the author concludes that hardness changes are in part due to variations in atomic structure. WLC (6)

On the Elastic Aging of Metal Wires. (Über das elastische Altern von Metallfäden.) G. FANSELAN. *Zeitschrift für Geophysik.* Vol. 8, No. 5, 1932, pages 226-232.

1 The elastic aging was studied on a brass wire (diam: .06 mm., length 45 cm., load: about 70 g.) The temporal course of elastic aging shows an exponential function with a definite dependence on the temperature. After 3 years the elastic disturbance seems to be completed. GN (6)

Comparison of Methods for Determination of Internal Stresses in Complete Cylinders. (Vergleich der Verfahren zur Bestimmung von Eigenspannungen im Vollzylindern.) HERBERT BUCHHOLTZ & HANS BÜHLER. *Stahl und Eisen,* Vol. 52, May 19, 1932, pages 490-492.

2 On basis of theory and practical measurements, a comparison was made of internal stresses in steel cylinders between drill method and the band method. Heyn and Bauer's drill method gives the total longitudinal, tangential, and radial stresses throughout the specimen but with the band method it is possible to obtain existing stresses only in one main direction. The drill method is the method absolutely to be used, while irregularities enter into the other method. The latter method does not give sufficient data and is entirely too irregular with highly stressed materials. DTR (6)

Influence of A.C. Magnetization on the Energy Absorption in Metals under Torsional Vibrations. (Einfluss der Wechselstrom- Magnetisierung auf die Werkstoffdämpfung bei Drehschwingungen.) A. ESAU & H. KORTUM. *Forschung auf dem Gebiete des Ingenieurwesens,* Vol. 3, May/June 1932, pages 144-150.

3 In continuing a former investigation on the effect of d.c. magnetization on the energy absorption of metals, the author examined the effects of a.c. magnetization. The testing arrangement is described. Tests were performed on wrought Fe, electrolytic Fe, rolled steel, alloy steel, Ni and a Ni-Fe alloy. The principal results are: (1) In most cases the effect of a.c. magnetization is still larger than that of d.c. magnetization. (2) All materials investigated show qualitatively the same behavior. The energy absorption in relation to the field strength shows a maximum at a relatively small field strength and decreases later. (3) The maximum increase of energy absorption is found at frequencies that are somewhat smaller than the mechanical natural frequency. (4) For small deformations the increase of energy absorption is many times larger than with large deformations. (5) The decrease of energy absorption for soft Fe and steel under the effect of a.c. is found at higher field strengths than under the effect of d.c. magnetization. (6) Alloy steels and Ni show a negative energy absorption within a certain range of the magnetization frequencies and for strong magnetization. (7) No relation was found between the behavior in the d.c. and a.c. field. (8) The frequency changes under the effect of a.c. magnetization were measured for electrolytic Fe, rolled C steel and alloy steel. These changes do not surpass the limit of error, i.e. they are smaller than .5% and .2% respectively.

The Effect of the Size of Specimen on the Strength and Elastic Properties of Cast Iron. A. H. DIERKER. *Engineering Experiment Station Bulletin* No. 72, *Ohio State University Studies,* Engineering Series, Vol. 1, No. 4, Part 3, July 1932, 16 pages.

6 Dierker objects to the arbitration bar, or to specimens cut from a casting and advocates testing the whole section of a casting in the size in which it is made. An iron of 3.00-3.20 total C, 1.80 Si, 0.12 P, 0.04 S, 0.52-0.62 Mn was cast into a 4" x 4" square bar and into a 1.2" diam. arbitration bar, both cast in green sand. Tensile data were concordant, but Charpy impact, on a double width, V-notch specimen, was 1.8 ft. lbs. on the arbitration bar and 3.3 to 4.1 on the 4" x 4". Similar tests on a 3.56 T.C., 0.178 Si, 0.16 P, 0.04 S, 0.60 Mn iron gave 2.5 ft.-lbs. for the arbitration bar and 3.0 to 3.4 on the 4" x 4". The softest and coarsest specimens gave the best impact values. From micrographs it is concluded that the presence of ferrite is probably desirable for impact resistance. The

7 second iron was tested in smaller sizes than 4" x 4" and tensile stress-strain curves plotted, showing the usual type of results. HWG (6)

The Thermoelectric Properties of Ferromagnetic Substances. L. F. BATES. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Ser. 7, Vol. 13, Feb. 1932, pages 393-412.

Theoretical work. Experiments made on the thermoelectric properties of short rods of manganese arsenide. Marked changes occur when the substance passes from the ferromagnetic to the paramagnetic state some specimens showing positive and some negative Thomson coefficients. RHP (6)

8 **Determination of Smoothness of Machine Parts. (Bestimmung der Glätte an Maschinenteilen.)** ERNST FRANKE. *Oberflächentechnik,* Vol. 9, June 21, 1932, pages 125-127.

The importance of smooth surfaces for certain machinery parts, such as axles, sliding faces, etc. is pointed out; the friction coefficient is reduced and the wear resistance increased. The means for determining the degree of smoothness are reviewed. This can be done, according to a French patent No. 687424, by a light ray directed against the surface to be examined; the reflected ray is then thrown on a photoelectric cell in which a current proportional to the re-

9 flected light is produced which can be measured by an instrument. Another method (German patent No. 544330) uses a disk which rolls along the surface to be tested and on the circumference of which one end of a spiral (watch-) spring slides. The roughnesses on the sample cause the spring to be wound more or less and the small movements can again be indicated by a dial. Another method uses a pendulum, the number of oscillations occurring before it comes to rest is taken as a measure of the smoothness; this method is suitable for round bodies. The results can be graphically represented. Ha (6)

10 **Test Results and Service Values of Materials.** H. F. MOORE. *Heat Treating & Forging,* Vol. 18, Apr. 1932, pages 245-247.

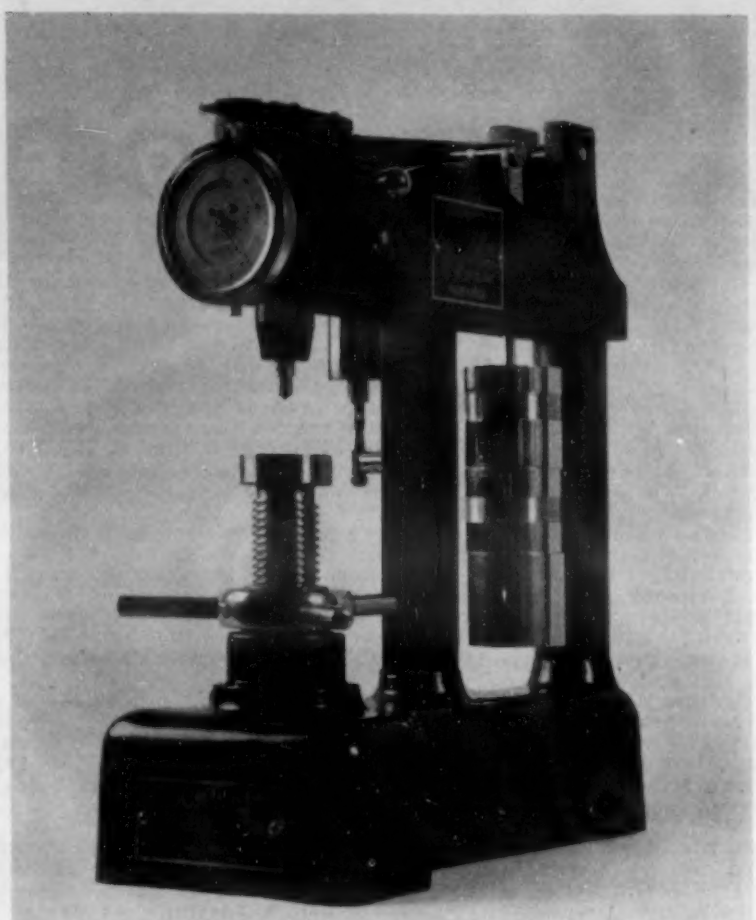
Fatigue of Metals & Alloys (6f)



The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

The Endurance Strength of Welded Joints. (Die Dauerfestigkeit von Schweissverbindungen.) W. HOFFMANN. *Elektroschweissung*, Vol. 3, Apr. 1932, pages 65-67.

Paper before Fachausschuss für Schweisstechnik, June 27, 1931 at Köln. The author summarizes and reviews recent investigations of the fatigue limit of welded joints. The principal conclusions are: The static tensile strength is of extreme importance for the endurance properties of all types of welded joints. In fusion welding the filling material must be so chosen that an increase of the elongation does not impair the tensile strength and hardness. In gas welding the tensile strength of the weld should always amount to 100% of that of the base metal. This value must be attained with regard to the fatigue strength of the weld. In arc welding filling materials should be avoided that may cause red shortness of the seam. Also filling materials are to be eliminated that, due to an infiltration of nitrogen, may cause brittleness or tend to age-hardening. Welds with such materials show a low fatigue limit. 8 references. GN (6f)

Increasing the Endurance Strength in Round Specimens with Transverse Holes. (Steigerung der Dauerfestigkeit bei Rundstäben mit Querbohrungen.) A. THUM & H. OSCHATZ. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 3, Mar.-Apr. 1932, pages 87-93.

Notch effect of transverse bored holes is explained by the disorder of the stress lines around the hole. The rim of the hole is greatly endangered due to the concentration of stress lines there. The varied notch effect of large holes is determined in fatigue tests, and their dependence is based on the ratio of the diameter of the bore to the specimen. Larger bores have smaller notch effect, smaller bores, greater. From the ratio $d/D = 0.15$ down, the notch effect of small bores increases. To increase the fatigue strength, 3 methods were investigated experimentally: (1) With an additional bored hole, necessarily placed at an angle of 90° (cross-bore), the resistance moment is equalized in rotating the direction of loading, and the fatigue strength of the specimen increased about 4.5%. (2) The strain lines may be led away from the rim of the hole by additional tangential notches so that an increase of endurance limit of 12% is obtained. (3) By setting up internal stresses the endangered points of stress at the opening of the hole can either be increased or decreased according to the location of the system. Corresponding increases of endurance limit up to 34% or decreases around 19% are obtained. Tests with impact loading confirm the influence of internal stresses upon the endurance strength. An increase of about 60% in the work of impact in the endurance test could be established, and for control a desired decrease around 40%. The tests have shown that it is possible in almost all cases to meet the danger of fatigue fracture in bored axles and shafts effectively and practically. It is hoped that undesirable effect of notches of other shapes can be reduced in a similar way. MAB (6f)

INDUSTRIAL USES & APPLICATIONS (9)

Replacements of Castings with Welded Steel Plate. G. D. SPACKMAN. *Welding News,* Vol. 3, Jan.-Mar. 1932, pages 1-2.

A great number of broken castings were replaced by welded structural parts. Besides, it is pointed out that with proper design, castings can from the beginning be well replaced by welded parts. See also *Metals & Alloys,* Vol. 3, Mar. 1932, page MA71. Ha (9)

1

Use of Silver and Gold Plate for Structural Apparatus for the Chemical Industry. (Utilisation des Plaques d'Argent et d'Or pour la Confection d'Appareils Employés dans l'Industrie Chimique.) CH. ZIEGLER. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 220-221.

In some cases it is necessary to use precious metals to protect apparatus from certain chemical attacks. This incurs a great and non-productive investment. Since it is necessary to combine strength, resistance and wearing ability to counteract this cost, the author suggests the application of an intermediate layer between the base metal and the plate to reinforce the strength of the plate and also to make soldering feasible. This makes the plate very applicable to many branches of the chemical industry. MAB (9)

2

Design for Casing Pipe for Pipe Undercrossings. M. G. SPANGLER. *Engineering News-Record,* Vol. 108, Apr. 27, 1932, pages 580-581.

Rapid extension of oil and gas lines required new specifications for the design of pipe for both railway and highway crossings. Calculations were based on Marston's conduit-load theory and the Boussinesq law of concentrated load distribution. A convenient tabulation of pipe thicknesses for varying conditions is included. CBJ (9)

3

House Frame Entirely Arc-Welded. *Sheet Metal Worker,* Vol. 23, Jan. 8, 1932, pages 6-7, 10.

Ordinary structural steel shapes were used for building a 7-room house and treated like wood lumber; the costs were only $24 higher than for a wood frame. The details of construction are illustrated. Ha (9)

Non-Rusting Steels a Possibility for Vehicle Construction. *Transit Journal,* Vol. 76, May 1932, pages 229-231.

Corrosion-resisting alloys of Cr, Ni and Fe are found suitable for ultra-light-weight structures. The properties, structure and heat treating possibilities of the usual 18-8 group of steels and other corrosion-resisting alloys are discussed. Development work on vehicles using sections of welded sheets is in progress. CBJ (9)

Aluminum Conductors for High-Capacity Electric Circuits. F. R. DALLYE. *Power,* Vol. 75, May 10, 1932, pages 685-687.

The use of Al conductors in the form of flat bars, tubing and structural shapes for bus connections is described. AHE (9)

Large Pipe, Strong Steel, 100% Joints Have a Profound Effect on Industry. G. O. CARTER. *Metal Progress,* Vol. 21, May 1932, pages 34-39.

In the construction of pipe lines over half the cost is steel. The author traces the development of better methods of making pipe and the production of pipe from stronger steel. A profound change in the pipe line industry has occurred with the introduction of sound pipe and welds of strong material enabling the industry to transport over 4 times as much gas per lb. of steel pipe as was possible 10 years ago. A 0.35% C, 1.50% Mn steel, seamless pipe, and improved welding technique have made this possible. WLC (9)

Aluminum Pipes in Gas Installations. (Aluminiumrohre in der Gasinstallation.) *Aluminium,* Vol. 14, Apr. 30, 1932, pages 2-3.

Al pipes and fixtures are well suited for domestic plumbing and industrial piping installations, but a protective coating of shellac, asphalt or by oxidation of the surface for which a few recipes are given should be applied. Special tools for Al pipes and their fixtures are being developed. Ha (9)

Cast Steel Foundations for Railroad Equipment. WM. M. SHEEHAN. *Steel Founder,* Vol. 3, Mar.-Apr. 1932, pages 39-42.

This installment brings descriptions of large castings used in the construction of locomotives and passenger cars. The repairs to cast steel parts has been found to be lower than for cast Fe parts. Ha (9)

10

Aluminum Casting Alloys in the Construction of Aircraft Engines. (Le leghe di alluminio da fonderia nella costruzione dei motori per aeronautica). C. PANSERI. *Alluminio,* Vol. 1, Jan.-Feb. 1932, pages 15-35.

Lists the usual light casting alloys, also Al bronzes and their tensile properties. Includes 38 figures, chiefly photographs of engines and engine parts. The tensile strengths of the different alloys at elevated temperatures are plotted up to 350° C. A diagram shows how shrinkage flaws at a change of section may be eliminated either by chills or by feeding. A hollow airplane propeller, of the Haw type, made in Berlin, in which the stress is supposed to be carried chiefly by alloy steel members inside the propeller, and which uses an Al alloy casting for the shell is illustrated, but Panseri does not think a cast alloy is suitable for such service. See also *Metals & Alloys,* Vol. 3, July 1932, page MA212. HWG (9)

Expanded Metal Sheets Find New Use in Stockroom Partitions. *Steel,* Vol. 90, Feb. 15, 1932, page 27.

Discusses the uses and advantages of expanded metal sheets for the construction of stockroom partitions. JN (9)

Material and Construction Problems of Fittings in Modern Steam Technique. (Material- und Konstruktionsfragen bei Amaturen in der neueren Dampftechnik.) F. A. M. WÜLLINGHOFF. *Die Röhrenindustrie,* Vol. 21, Jan. 15, 1931, pages 13-15, Jan. 29, 1931, pages 26-29; Feb. 12, 1931, pages 38-40.

Cast iron, bronze (86 Cu, 10 Sn, 4 Zn), Monel metal, alloy steel as well as the different metallic and non-metallic gaskets for valves are considered. At high temperatures (500° C.), special bronzes with additions of Al, Sb, Fe, Mn, Ni, Si are developed. The use of Mo-bearing cast steel or of nitrided fittings is recommended. Then the material for gaskets, flange screws, fittings in touch with fuel or lubrication oil, compressed air, blast furnace or city gas, ammonia, chemical reagents are discussed. The balance of the paper pertains to the design of fittings, their manufacture and mounting. EF (9)

Light Metal Carriages. (Leichtmetall - Stadtbahnwagen.) C. WAGNER. *Glasers Annalen,* Vol. 55, Dec. 1, 1931, pages 100-109.

German State Railways ordered 2 trains of cars of light metals. The 2 different designs of the Linke-Hoffmann-Busch Works, Bautzen, and of the Wegmann Co., Kassel, are described in detail. In spite of the fact that a comparison is made with interborough express train cars of steel which are appreciably lighter than ordinary railway cars, the weight of the former cars is reduced by 8.5% and 11.5% respectively due to the utilization of light metal alloys. EF (9)

Jigs and Fixtures Made of Welded Steel. J. R. WEAVER. *Metal Progress,* Vol. 21, Mar. 1932, pages 32-36.

The production of jigs and fixtures is speeded up and cost reduced by substituting welded plates and base for cast iron. Standard hot rolled steel plate and bars may be carried in stock and modified by oxyacetylene cutting. Maintenance cost of steel fixtures is only 15% of that for cast iron tools. Welded jigs require normalizing to a temperature of 1000°F. WLC (9)

A Large Span All-Welded Building. HOPE A. MCCREADIE. *Welder,* Vol. 3, May 1932, pages 3-7.

Construction details of stanchions, N-type roof girders, roof trusses, purlins, bracings, gutters and their supports for a building of 160 feet, span are described. Ha (9)

Welded Highway Bridge in New Zealand. P. B. MACDOWELL. *Welder,* Vol. 3, May 1932, pages 37-40.

A bridge comprising 6 spans of 80 ft. each was strengthened by arc welding stiffeners to it. Construction details and the methods of procedure are described. Ha (9)

Wrought Iron Disappearing from Europe. Correspondence from F. G. MARTIN. *Metal Progress,* Vol. 21, Apr. 1932, pages 68-69.

Writer comments on the decreased production of wrought Fe in the British Isles. The present inactivity in the shipbuilding industry is largely responsible for the slump. WLC (9)

The Suitability of Widia Cutting Edges for Drilling in Solid Rock. (Ueber die Eignung von Widia-Schneiden beim Bohren im festen Gestein.) O. MUELLER & H. WOEHLBIER. *Krupp'sche Monatshefte,* Vol. 13, Mar. 1932, pages 89-98.

Drilling tests were made with different types of cutting edges of Widia metal (tungsten carbide) in rock salt, slate and sandstone and the energy consumption determined. The practical problem can be considered as solved but the economical advantage can be determined only by practical test in the individual case. The apparatus, shape of tools and test methods are described and the results tabulated showing energy consumption in the different cases. Ha (9)

Fine Finish on Metal Furniture. W. V. MORROW. *Metal Progress,* Vol. 21, Apr. 1932, pages 27-32.

The steel finding widest application in the furniture industry is a high grade, open-hearth sheet (C 0.05-0.10%) which is reannealed, full pickled, cold rolled, stretcher leveled, resquared, and oiled to prevent corrosion as a preliminary to the manufacturing operations. The actual finishing frequently includes 2 cleaning operations, 3 sandings, 5 bakings, one graining, and one rubbing in addition to the application of several coats of varnish. Finishing treatments are rigidly controlled by examination of test specimens. WLC (9)

Pistons of Aluminum Alloy for Diesel Motors. (Pistons en Alliage d'Aluminium pour Moteurs Diesel.) G. MORTIMER & J. F. PAIGE. *Revue de l'Aluminium,* Vol. 9, Jan.-Feb. 1932, pages 1621-1637; *Alluminio,* Vol. 1, May-June 1932, pages 145-159.

The process of making cast pistons of Al alloy is described very fully, the advantages due to greater lightness and elimination of seizing often happening with cast steel or cast iron pistons are pointed out. The design is described in detail; the alloy employed has an expansion coefficient of only 0.0000119. The heat treatment consists in heating at first rapidly to 530° C. and quenching in water; then heating normally to 530° C. and quenching again; the third time it is heated to 530° C. but left to cool in air; after this it is heated a fourth time to the same temperature very rapidly and cooled slowly in air. The material now has a breaking strength of 12 tons/in.², elongation none, Brinell hardness of 70 to 80. The manufacturing process is illustrated. AWC+AH+Ha (9)

HEAT TREATMENT (10)

Methods of Heating and Cooling Wire. J. A. Doyle. *Wire & Wire Products,* Vol. 7, May 1932, pages 141-144, 169; June 1932, pages 190-195, 206.

The uniformity of wire products depends greatly on the heat treatment; the points to be taken care of in temperature control, uniform exposure to heat and manner of cooling are discussed and their relation to quality and cost considered. Part II. Deals particularly with the proper care during heating and cooling and gives diagrammatic sketches of various furnaces with built-on cooling or quenching arrangements. The fuel question in connection with bright annealing and clean annealing, and the use of electric or fuel heating is discussed at length. Ha (10)

High Speed Steel. O. W. Ellis. *Canadian Chemistry & Metallurgy,* Vol. 16, June 1932, pages 173-176, 178; July 1932, pages 204-205.

A discussion of certain characteristics of 18-4-1 steel in the solid state and of results of experiments conducted by the Ontario Research Foundation in conjunction with some Ontario members of the A. S. S. T. Several photomicrographs are shown which permit judgment as to the treatments accorded the specimens examined. The most important point brought out by the joint tests is that, despite differences in the type of equipment and of technique, very uniform results can be obtained in the heat treatment of high speed steel by workers following the specified procedure. Drawing at 1000°F. results in a great uniformity of hardness. It may be due to almost complete precipitation of such carbides as have been held in solution by the steel as a result of quenching. WHB (10)

Can Cracking Be Eliminated? (Peut-on éviter les tapures). Jean Chanzy. *Revue de Métallurgie,* Vol. 29, June 1932, pages 281-300.

No cracking on heating or cooling will occur in a metal when the dilatation of it in a given interval is less than the elongation of the metal at the same temperature. Only the surface layer of the metal should be considered in studying the temperature effects. The coefficient of dilatation is fairly well known from dilatometric curves. The elongation at elevated temperatures can be determined by actual experiments, though an assumption must be made that the elongation along all 3 axes of coordinates is the same which is not the case. Cracking limits for given temperatures are expressed by a curve which is a function of elongation-dilatation ratio. With this curve it is possible to derive by a simple graphic method the limits of the temperature gradients both in heating and cooling which would not produce cracking when applied to the given metal. For practical purposes these steps are around 500°C. The curve of cracking usually shows a maximum at about 200°C. and a minimum at about 500°. In such a case the following steps can be used for heating: 120°, 500°, 950°, 1450° and for cooling: 1450°, 610°, 330°, 0°. When sharp maxima and minima are lacking a division of the temperature into uniform steps of 450°-500° would produce satisfactory results. This division of the heating range is particularly important because most of the common defects in steel are caused not by an absolute temperature but by the large temperature differences. Application of this principle to heat treating of high speed steel (0.7 C, 18 W, 4.5 Cr, 0.8 Mo, 0.8 V) showed that for 13 mm. squares the substitution of the usual recommended treatment (10 min. at 150°, 28 min. at 900°, 3 min. at 1325°C.) with subdivided heating (3 min. at 450°, 3 min. at 900°, 3 min. at 1325°C.) in both cases followed by an identical quenching in oil has given a better hardness for the short time treatment. The latter treatment followed by divided quenching using furnaces heated to 860°C., to 450°C. and the final air cooling produced a better hardness than the usual heating cycle and the oil quench. 3 minute intervals were allowed for each furnace. No drawing was used, but the results obtained were only a little lower than those obtainable with the same heating method and the optimum drawing treatment and were somewhat higher than the figures produced by the usual quenching practice and the best known drawing. As long as quenching can be considered as a means for prevention of certain reactions taking place in steel on normal cooling, it can be thought that for a given steel the reactions will depend on temperature and composition alone. Plotting curves not involving time element by using for ordinates the amounts of the transformed matter we shall see that the apparent transformation point is considerably lower than that derived from theoretical considerations. On account of this the transformation point of a steel heated to a higher temperature appears to be lower because for a given temperature the cooling speed is lower the higher is the temperature from which the cooling started. This can be easily checked with a dilatometer. With the repeated short heatings it does not seem to be necessary to increase the quenching temperatures to the usual range in order to produce the same amount of transformation on quenching. The speed of quenching is greatly affected by the dimensions of the article, the composition of steel and the character of quenching media. Comparing the curve representing the reactions in steel which are to be suppressed by quenching with the diagrams showing the speed of cooling obtainable on subdivided quenching we can see whether the intensity of the quenching action in any given period is sufficient, more than sufficient or insufficient to produce the corresponding transformations, as compared with those obtainable with the usual practice. 3 examples of steels are given to illustrate these 3 possibilities. The determination of cooling curves was made by a calorimetric method. A table is given presenting the rates of transformation in steels treated in the usual and the new method covering the whole range. A formula for the determination of the rate of the decomposition is proposed. The paper is illustrated with 33 diagrams and microphotographs. JDG (10)

Welding & Cutting (11c)

Resistance Welding of Aluminum. D. I. Bohn. *Industry & Welding,* Vol. 3, Mar. 1932, pages 18-20.

Due to its considerably higher heat and electric conductivity and greater mechanical weakness just below the melting points, automatic resistance welding of Al requires a different setting of the welding outfit from that for steel welding. The conditions for butt welding and the setting of the electrical relays are briefly discussed. Ha (11c)

Gas Welded Steel Structures at the German Building Exhibition, Berlin, 1931. (Autogen geschweisste Stahlbauten auf der deutschen Bauausstellung, Berlin, 1931.) W. Boos. *Zeitschrift für Schweisstechnik,* Vol. 21, Aug. 1931, pages 177-182.

A curious 3-story diving tower 10m. in height assembled by gas-welding is detailed. The accomplishment of the strut connections are stressed showing the remarkable possibilities of this joining method. A gas welded exhibition hall of 90 m. over-all length is regarded as the largest structural frame of its kind in Europe. Gas welded steel radiators are claimed to be superior to cast iron ones. EF (11c)

The Fusion Oxy-Acetylene Welding. (La Soudure Autogène Oxy-Acétylénique.) André Bilard. *Revue Universelle des Mines, Series* 8, Vol. 7, Feb. 15, pages 276-291.

Historical development of the method, apparatus for its application, the manufacture of oxygen and acetylene, best methods for economy and quality for steel as well as for other metals, requirements for the welding rods, testing methods of the welds are treated in detail and a number of illustrations of welded parts and structures are given. The advantages of oxy-acetylene cutting are also discussed. Ha (11c)

Applying Welding in the Piping Industry. H. F. Bartlett. *Welding,* Vol. 3, Apr. 1932, pages 245-248.

Development of pipe fittings for welded installations has contributed largely to the growth of this field. There is a need for the development of design standards which will make full use of the engineering knowledge already available on the entire subject of piping. TEJ (11c)

The Experimental Determination of the Values of Fillet Welds in Tension. Leon C. Bibber. *Journal American Welding Society,* Vol. 11, May 1932, pages 16-19.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author sets forth his theory for the calculation of stresses in fillet welds under tension and shows by actual weld tests a remarkable agreement between calculated and actual values. TEJ (11c)

Demolition Bombs, the Use of Modern Welding Processes of Manufacture. H. S. Beckman. *Army Ordnance,* Vol. 12, Mar.-Apr. 1932, pages 341-344.

The particular requirements of material and welds for aerial bombs are set forth and the manufacturing processes are described. Only circumferential welds have stood the severe tests of dropping from more than 2000 ft. altitude on hard bodies. The best results were obtained with the atomic hydrogen process of welding in which nose and tail steel forgings were welded circumferentially to a seamless steel tube. Ha (11c)

Welding of Non-Ferrous Castings. (Das Schweissen von Nichteisen Metallgussstücken.) E. Becker. *Das Metall,* Jan. 4, 1931, pages 1-3.

Application of welding to Cu, Al, Ni and their alloys. WHB (11c)

Arc-Welding Sheet Metal. E. P. Bestler. *Sheet Metal Worker,* Vol. 23, Jan. 22, 1932, pages 37-38, 42.

The advantages of fabricating sheet metal products by arc welding over the old system of riveting and soldering are discussed and illustrated by examples. Important savings can be made in raw material and in labor. Ha (11c)

Welding of Non-Ferrous Metals. (Schweissen von Nichteisenmetallen.) Adrian. *Die Schmelzschweissung,* Vol. 11, Apr. 1932, page 69.

This is a brief report of a symposium held in Frankfurt a. M. by the Verein deutscher Ingenieure, where several speakers enlarged on the present status and progress made in the different welding methods. Particular emphasis was laid on the Arcogen method with which Cu, Ni, Monel, brass and Al can be welded. Other speakers dealt with the strength of welds of duralumin for which satisfactory results are now obtained. Ha (11c)

Remarks on Paragraphs 10 to 12 of the New Welding Code. (Bemerkungen zu § 10/2 der neuen Schweissvorschriften.) Hans Schmuckler. *Die Bautechnik,* Vol. 10, *Der Stahlbau,* Jan. 22, 1932, pages 15-16.

Discusses the methods used and recommended in testing welds: X-ray, stethoscope, sampling, chipping, grinding the weld to the core and etching with cuprous ammonium chloride (Schmuckler's process). MAB (11c)

A Further Practical Suggestion: Sheet Metal Electric Signs. *Sheet Metal Worker,* Vol. 23, Feb. 5, 1932, page 57.

Fabrication by welding of large signs eliminated trouble of creeping joints. Ha (11c)

The Welding of Wrought Iron. James Aston. *Journal American Welding Society,* Vol. 11, May 1932, pages 19-24.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author gives a historical outline of the manufacture and uses of wrought iron and discusses its chemical and physical properties. The fusion welding characteristics of wrought iron are given, both plastic and fusion welding being considered. Wrought iron possesses in the highest degree the composition and characteristics which are fundamental to good welding. TEJ (11c)

The Progress of Metallic Arc-Welding in the Electrical Engineering Industry. *The Welder,* Vol. 3, Feb. 1932, pages 21-26.

The paper illustrates the utility and economic advantages of welding in the manufacture of machinery for the electrical industry by many examples of welded structures over castings and shows in a table the comparative weights and cost per pound and the saving in cost for structures varying from 140 to 21,300 lbs. welded weight; the savings in weight range from 20 to 66%. Semi-automatic welding, especially where large quantities of metal have to be deposited is recommended. Ha (11c)

Hard Surfacing High Carbon Steel. W. A. Wissler. *Industry & Welding,* Vol. 3, Apr. 1932, page 23.

Stellite is applied on the thoroughly cleaned steel surface by a carburizing flame; it flows in much the same way as solder and wets the surface of the steel. Ha (11c)

1 **Welded Masts of Steel Tubing. (Geschweisste Stahlrohrmaste.)** J. Wanke. *Die Bautechnik,* Vol. 10, *Der Stahlbau,* Jan. 8, 1932, pages 6-8.

Investigations included tests on stresses applied to joints, on bending strength of welds, on elasticity, and on torsion strength of joints. MAB (11c)

Engineering and Economic Study of Electric Arc Welding. C. L. Waddell. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 52-54.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. Essentials of

2 good welding design are: (1) complete knowledge of the conditions of service, (2) an accurate analysis of the stresses, (3) proper selection of materials, (4) consideration of economy in fabrication. Essentials of good weld fabrication are: (1) good materials of known chemical composition and physical characteristics, (2) adherence to a definite proved weld procedure, (3) skilled workmanship, (4) competent supervision and inspection. The author describes tensile, bend and nick-break tests made to determine physical properties, particularly ductility, of welds made with various electrodes, both bare and covered. Various factors affecting ductility of welds are listed. TEJ (11c)

3 **Laboratory for Welding Studies.** J. R. Townsend. *Bell Laboratories Record,* Vol. 10, May 1932, pages 306-310.

A brief enumeration of the uses of welding with special reference to small work used in telephone apparatus, the methods applied and description of X-ray testing equipment. The new laboratory to study welding processes for the different purposes contains automatic, semi-automatic and hand arc welding, oxy-acetylene gas welding and atomic hydrogen welding equipment. Ha (11c)

Problems Encountered in Flash Welding. E. R. Torgler. *Welding News,* Vol. 3, Jan.-Mar. 1932, pages 2-6.

4 Four problems in the manufacturing process of Dresser flexible pipe couplings of mild steel were met by welding. The whole procedure is described in detail. Ha (11c)

Electric Welding in South America. J. Thomas. *Welder,* Vol. 3, Apr. 1932, pages 21-24.

Notes on the present status of welding in Brazil, Argentine and Chile. Some examples are illustrated. Ha (11c)

Recent Developments for Welding Pipe. Herbert P. Smith. *Welding,* Vol. 3, June 1932, pages 381-384.

Some suggestions, shortcuts and costs for the installation of various piping jobs. TEJ (11c)

5 **The Welding Designer. (Der Schweisskonstrukteur.)** A. Volke. *Die Schmelzschweissung,* Vol. 11, May 1932, pages 89-92.

Attention is again called emphatically to the necessity for the designers in all branches of engineering who employ fusion welding processes abandoning the traditional methods and designing principles used in riveted construction and taking in account the particular character of a weld. The designer must be familiar with the metallurgical and physical properties of the weld and the influence of heat, welding rod, gases, machines, torch and, most important of all, the welder himself. Some typical designs for welded constructions are described. Ha (11c)

6 **Welding Wires for the Acetylene-Welding of Steel. (Ueber Schweissdrähte für die Azetylenschweissung von Stahl.)** E. Streb. *Autogene Metallbearbeitung,* Vol. 25, Feb. 15, 1932, pages 52-61.

From a survey of the materials used as welding rods for steel and of the results obtained the following requirements are stated: 100% tensile strength with high elastic limit especially for dynamically stressed structures; a certain content of Mn, Ni, Cr and Mo is advocated; the wire should have 100% strength and flow easily, must not spatter and not form pores. A number of diagrams show the relation of

7 quality of seam to the content of P and Mn, the influence of C, and a few micrographs illustrate the structure of good welds. Ha (11c)

A New Portable High-capacity Torch. (Ein neues transportables Hochleistungsgebläse.) O. P. van Steewen.-*Die Schmelzschweissung,* Vol. 11, Apr. 1932, page 77.

A handy, compact blower built into the airchamber gives pressures of 300 to 2000 mm. Hg and can feed 4 to 6 torches for gas, acetylene, etc., or can be combined with a gas line torch. Ha (11c)

Gas Protection During Gas Welding and Cutting. (Gasschutz beim autogenen Schweissen und Schneiden.) G. Stampe. *Dräger Hefte,* No. 158, Nov./Dec. 1931, page 2060.

8 The special cases of welding and cutting which make the utilization of gas masks indispensable are considered: works accomplished in closed containers, evaporation of metals included in the welding material or coating, generation of poisonous metallic vapor. EF (11c)

Electric Arc and Resistance Welding and Their Applications in Industry. (Les Soudures Electriques a l'Arc et par Resistance et leurs Applications dans l'Industrie.) Theo. Sunnen. *Revue Technique Luxembourgeoise,* Vol. 23, Nov.-Dec. 1931, pages 250-258.

9 The great advantages of electric welding, both by arc and by resistance, in manufacturing processes, maintenance, repairs, etc., are pointed out and the electrical equipment is described. Ha (11c)

Determination of the Capacity of a Blow-Pipe. (Determination de la Puissance d'un Chalumeau.) Seferian. *L'Usine,* Vol. 41, Mar. 11, 1932, pages 31-33.

A diagram is developed which gives the capacity of a torch in liters of acetylene as a function of the thickness of steel. Al, Cu and Pb to be welded or soldered. Ha (11c)

Welding Extensively Employed in Steel House. Henry Dubin. *Welding,* Vol. 3, Jan. 1932, pages 15-19, 27.

10 Complete description of welded steel house designed by and built for the author. Masonry walls and battledeck floor construction was used. Sections were fabricated in the shop by use of arc welding, delivered in trucks and field welded into place. About ¼ of the total welding was done in the field. Advantages of this construction are given. Illustrations included. TEJ (11c)

The Welding of Girder Structures. (Schweissen von Fachwerken.) H. Schulz. *Die Schmelzschweissung,* Vol. 11, May 1932, pages 93-97.

The procedure for the welding of a bridge must be entirely different from that of riveting the same structure. The example of a bridge is given of a total length of 83.15 m. with 5 spans of 18, 17.5 and 11.65 m. and built up of tubes. The calculation is given in detail. The process as described is such that no internal stresses will occur in the welded structure which might lead to deformations later on. The saving obtained by acetylene welding of this structure over riveting amounted to 13%. Ha (11c) 1

Assuming Responsibility for Structural Welding. E. E. Seelye. *Engineering News-Record,* Vol. 108, May 26, 1932, pages 769-771.

Engineer handling his first welded building, Yale University dormitory quadrangle, outlines precautions and procedure that he found useful and efficient. CBJ (11c) 2

The Safety of Boiler Welding Seams with Special Consideration of Internal Stresses. (Die Sicherheit von Kesselschweissnähten unter besonderer Berücksichtigung von Eigenspannungen.) S. Sandelowsky. *Elektroschweissung,* Vol. 3, Apr. 1932, pages 61-64.

It is shown that regardless of the internal stresses set up but under due consideration of all the other factors electrically welded seams in boilers guarantee the same degree of safety as water gas welded seams. Whereas the load permitted for water gas welded seams in Germany amounts to 10,800 lbs./in.^{2} that for electrically welded seams is but 6100 lbs./in.^{2} Due to the favorable results with the electrically welded seams the author wants a revision of the German standards for electrically welded seams. 6 references. GN (11c) 3

Progress Made in Construction of Pressure Vessels. G. Raymond. *Welding,* Vol. 3, Apr. 1932, pages 226-230, 257.

Abstract of paper presented before the Tulsa Section of the A.S.M.E. The general acceptance by the petroleum industry, largely in the past 2 years, of fusion-welded pressure vessels for a wide and increasing variety of purposes, is indicative of the progress made in pressure vessel construction. Causes which have contributed to acceptance of welded pressure vessels are: (1) General improvement in quality of all welds, (2) The entire leak-tightness of welded vessels, (3) Economy, (4) Corrosion resistance of quality welds, (5) Ability to construct vessels of great wall thickness. The author reviews early methods of fabricating pressure vessels and then describes the modern shielded arc principle of welding. The A.S.M.E. boiler code and its relation to oil industry uses are discussed. The author points out the importance of having good base metal and illustrates some problems in design of pressure vessels. TEJ (11c) 4

Gas Cutting. (Das Autogen-Schneiden im Vorrichtungs- und Werkzeugbau.) K. Schmelzer. *Zeitschrift für wirtschaftliche Fertigung,* Mar. 1932, pages 32-34.

A simple gas cutting machine is described which is distinguished from former constructions by its light weight. The new machine is most adaptable to cutting pieces of mass production. The paper concludes with a review of the composition of high alloy steels which can be cut with a cutting torch. GN (11c) 5

Increase of the Resistance to Repeated Impacts of Welded Pieces. (Augmentation de la Resistance aux Chocs Repetes des Pieces assemblees par Soudure.) D. Rosenthal. *L'Usine,* Vol. 41, Feb. 5, 1932, page 31.

The endurance resistance of welded pieces is usually diminished in the zone between the base of the parent metal and the deposited metal. This condition can, however, be improved by first caulking the zone of the junction. This results in a lengthening of the material in the direction of the axis of junction and in an upsetting effect in the direction across. It is explained that the inner stresses set up by this treatment are the cause of the improvement. The successful treatment, however, requires that the material possess a good ductility. Ha (11c) 6

American Regulations for Fusion Welding of Steam Boilers and Pressure Vessels. (Amerikanische Vorschriften für Schmelzschweissung an Dampfkesseln und Druckgefässen.) F. W. Rudel. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Apr. 1932, pages 99-103.

The article includes American practice with regard to requirements for welding, the evaluation of welds according to the purposes for which the vessels are used, X-ray testing and other means for testing of welds, hydrostatic tests, and the requirements for annealing welded parts. MAB (11c) 7

The Development of the Automatic Resistance Fusion Welding. (Die Entwicklung der selbsttätigen Widerstands-Abschmelzschweissung.) E. Rietsch & S. Sandelowsky. *Elektrotechnische Zeitschrift,* Vol. 53, Mar. 3, 1932, pages 197-199; *A. E. G. Mitteilungen,* Mar. 1932, pages 111-112.

The conditions for a good welding joint are: 1. the preheating (if necessary) must take place very rapidly and the heated zone must be small; 2. the time of fusion must be correctly chosen under proper secondary voltage; 3. upsetting (pressing together) must take place like an impact whereby the upsetting pressure must have a definite value depending on the section. Several automatic resistance welding machines are discussed with regard to fulfillment of these requirements. The best machines are controlled by a cam which regulates the 3 conditions according to the sections to be welded. Ha (11c) 8

Strength and Calculation of Welded Joints in Structures Subject to Bending. (La Résistance et le Calcul des Joints Soudès dans les Pièces Fléchies.) D. Rosenthal. *Génie Civil,* Vol. 69, Oct. 3, 1931, pages 365-367.

The stresses to which welded girders of composite sections are subjected when bending moments occur besides tensile or compression stresses are treated analytically and tested on samples. The test results show that the actual strength is greater than the calculated strength. This is attributed to a gradual equalization of the tensions from the exterior fibers of the structure to the fibers near the neutral axis. Diagrams illustrate the distribution of stresses. Ha (11c) 9

Coated Electrodes. (Ein Beitrag zur Beurteilung ummantelter Elektroden.) J. Petry. *Elektroschweissung,* Vol. 3, Feb. 1932, pages 25-27.

The author studied the effect on the weldability of various coated electrodes with special reference to the formation of slags and holes. Some practical hints are given as to how coated electrodes are to be used to avoid the disadvantageous effects of the slags formed. GN (11c) 10

The Prevention of Fractures of Circular Seams. (Ueber die Verhütung von Rundnahtbrüchen.) H. W. Nies. *Die Schmelzschweissung,* Vol. 11, Mar. 1932, page 47.

The author points to the often observed danger in circular welds of containers leading to fractures on account of shrinking stresses set up by the welding process and not removed afterwards by proper treatment. The best means for the prevention of these stresses is adequate shaping of grooves, etc. close to the weld which absorb the stresses. Ha (11c) 11

Defective Designs of Acetylene Apparatus. (Fehlerhafte Konstruktionen von Azetylenapparaten.) Emil Menz. *Autogene Metallbearbeitung,* Vol. 25, May 15, 1932, pages 147-152.

The design of an acetylene gas producer must take into account as one of the most important requirements that the gas generation does not become too strong especially after temporary overloads; the water access and removal must therefore be arranged so that it quickly responds to the demand for gas. Existing constructions are examined in this respect and the reasons for failures analytically determined. Proper attention should be paid to the cooling of the apparatus and the gas, and the depth to which the carbide can be immersed must not be allowed to produce more gas than the apparatus is rated to give. Cooling of the gas tends also to reduce the cost of welding as the acetylene does not contain so much water vapor. These points are more important if there are several welding places fed from the same acetylene apparatus. Ha (11c) 12

The Practical Application of the Arcogen Welding Method with particular Consideration of Its Suitability for Welding of the Technically Important Materials. (Die praktische Anwendung des Arcogen-Schweissverfahrens unter besonderer Berücksichtigung seiner Geeignetheit für das Schweissen der technisch Wichtigen Werkstoffe.) H. Muenter. *Schmelzschweissung,* Vol. 11, Feb. 1932, pages 33-35; Mar. 1932, pages 54-59.

Extensive tests with ferrous and non-ferrous metals permit the conclusion that the arcogen welding method is quite suitable for high-C and alloyed steels and that even higher welding velocities can be applied; especially for Cu and Al and their alloys do high welding velocities offer economical advantages. This is not true of Cu alloys with high Zn contents. Numerous micrographs demonstrate the quality of the weld. Ha (11c) 13

"Premag" Welding of Copper in Australia. J. D. Millar. *Industrial Gases,* Vol. 13, Mar. 1932, pages 28-30.

"Premag" consists of a base-metal filler-rod and cleaning flux and its use for oxy-acetylene welding of non-arsenious Cu is discussed. Typical test figures for welds are: Maximum stress is 13.5 tons/in.^{2} and elongation 32.5% in 4". As to the corrosive resistance of the weld, only a small amount of Cu_2O should be retained. Suitable for work on larger Cu tubing up to 8" in diam., reclamation of Stearine tubes, chlorinator lining, acid vats, and washers, ice-cube boxes. As and high O in the Cu are both fatal to the weld. DTR (11c) 14

Welding of Monel Metal (Das autogene Schweissen von Monel-Metal im chemischen Apparatebau). R. Müller. *Der Apparatebau,* Vol. 44, Feb. 19, 1932, pages 29-32.

The paper briefly outlines the methods and fluxes to be used in welding Monel metal. Examples of the practical application of welded Monel metal parts are given. GN (11c) 15

The Present State of Electric Arc Welding. (État Actuel de la Soudure par l'Arc Électrique.) H. Michel. *Revue Universelle des Mines,* Series 8, Vol. 7, Feb. 15, 1932, pages 261-269.

A review and description of the methods now in use for joining metals by the electric arc, with micrographs of welds and illustrations of machinery and structure built up by welding. Ha (11c) 16

Estimating Welding in Multi-Story Buildings. Frank P. McKibben. *Welding,* Vol. 3, June 1932, pages 364-366.

The author presents a table of data for welding steel building frames which gives important information concerning 6 large welded structural steel projects. The table is intended for use as an aid in estimating welding on structures similar to the ones listed. TEJ (11c) 17

Altering Wrought Iron and Steel Bridges by Welding. Frank P. McKibben. *Journal American Welding Society,* Vol. 11, Mar. 1932, pages 21-25; *Canadian Engineer,* Vol. 62, Apr. 26, 1932, pages 17-18.

Paper presented at the annual convention of the American Road Builders Association by the author, as a representative of the American Welding Society. Causes which necessitate bridge alterations are: (1) Corrosion, (2) Cracks due to overloading or to defective metal, (3) Excessive stresses, (4) Readjustment of existing members. The article is well illustrated with sketches. VVK+TEJ (11c) 18

Welded Steel Structures. Hope A. McCreadie. *The Welder,* Vol. 3, Feb. 1932, pages 10-13.

The author points to the still greatly varying working stresses in bridges or large girders of different designs and emphasizes the necessity of accurate formulas being developed for the careful design of practical welded structures; the experience of all countries should be taken into consideration in fixing standards. Ha (11c) 19

Cause and Cure of Intergranular Corrosion in Austenitic Steels. John A. Mathews. *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 23-27.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The wider use of austenitic steels has been retarded due to fear of failure from intergranular corrosion. The author describes 3 methods of preventing intergranular corrosion, (1) use of low C austenitic steels (.07 max.), (2) heat treatment of welded parts to redissolve the precipitated carbides, (3) the addition of inhibitors such as Ti, Si, Va, Mo, and W to the austenitic Cr-Ni steels to prevent or greatly retard intergranular susceptibility. TEJ (11c) 20

Welded Building Construction as now Practiced. Gilbert D. Fish. *Welding*, Vol. 3, May 1932, pages 301, 323-324.

In order to become well informed on this subject, an engineer should learn the requirements of safe design, the elements of economy and the methods used to insure proper workmanship. TEJ (11c)

Welding Heavy Castings in an Engine Shop. W. M. Elliott. *Industry & Welding*, Vol. 3, Apr. 1932, pages 8-10, 31.

Methods for welding heavy castings are described, particularly the prevention of the heat flowing away too quickly and the preparation of the parts to be welded together; the convenience for the welder is also considered. Slow preheating to about 1200° F. is recommended. Ha (11c)

Advantage for Insulating Technique in the Use of Welding in Building of Pipe Lines. (Vorteile für die Isoliertechnik bei Anwendung der Schweisstechnik im Rohrleitungsbau.) Paul Eising. *Die Schmelzschweissung*, Vol. 11, Apr. 1932, pages 66-69.

The employment of welding processes in installing pipe lines has led to considerable economies particularly if the lines have to be insulated for heat or cold, on account of the lack of flanges which greatly simplifies the labor and material for insulating. An example of a 100 m. long steam line shows the differences in heat loss for different conditions and with and without flanges. Another advantage is obtained for vertically running lines as the weight is less and the supports can be lighter and also welded on. Ha (11c)

Discussion of the Symposium on Ductility of Weld Metal. G. Doan. *Journal American Welding Society*, Vol. 11, May 1932, pages 26-28.

The author discusses ductility of welds, referring to various opinions presented at the Symposium on Ductility of Weld Metal at the Annual Meeting of the American Welding Society in New York, Apr. 1932. It is the author's opinion that high ductility of weld metal is desirable since the danger of cracking during cooling will be greater in the weld than in the joined parts due to (1) greater local shrinkage in volume; (2) greater concentration of stresses by flaws in the weld; (3) weaker condition of the hotter metal. TEJ (11c)

Some Methods and Effects of Machine Gas Cutting. L. M. Curtiss. *Paper* read before the 32nd Annual Convention, *International Acetylene Association*, Nov. 1931, 6 pages; *Journal American Welding Society*, Vol. 11, Jan. 1932, pages 19-22; *Blast Furnace & Steel Plant*, Vol. 20, Mar. 1932, pages 270-271; *Metallurgist*, Feb. 1932, pages 29-30.

Welded Steel and Galvanized Tanks. Joseph C. Coyle. *Welding*, Vol. 3, May 1932, pages 303-304.

Description of several practical "shop-kinks" which have been devised in tank shop to expedite production. TEJ (11c)

General Discussion on Ductility. J. H. Critchett. *Journal American Welding Society*, Vol. 11, May 1932, pages 28-29.

A general discussion of the papers presented at the Symposium on Ductility held at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author concludes that while ductility in weld metal is an important element, extreme ductility is not necessary and is a minor element as compared with sound design, choice of high grade materials, careful attention to fabrication and thorough proof testing before use. TEJ (11c)

New Aspect in Pipe Welding. Willard P. Curley. *Journal American Welding Society*, Vol. 11, Apr. 1932, pages 33-35.

Paper presented at the Annual Meeting of the American Welding Society in New York, Apr. 1932. The author briefly traces the various cycles through which the application of welding pipe has passed and discusses recent progress in this field. TEJ (11c)

Special Shielded Arc Technique Used in Welding Sheet Metal Hoppers for Coal Stokers. A. F. Davis. *Sheet Metal Worker*, Vol. 23, Mar. 4, 1932, page 109.

A magnetic field is used which controls and focuses the carbon arc of a small diameter carbon along the line of fusion. No welding wire is used, a flux is painted on the edges to be welded which gives off a gas, shielding the metal while molten; a weld of good tensile strength and extreme ductility is obtained in this manner. The method is used in mass production. Ha (11c)

What Does It Cost to Weld Pipe and Fittings? Arthur E. Christen. *Welding*, Vol. 3, June 1932, pages 385-388.

The author offers a standard method of calculating welding costs. TEJ (11c)

The Effect of Flame Cutting on the Properties of Steel. (L'Effet du Découpage au Chalumeau sur les Propriètès de l'Acier.) Charles Cehasse. *Revue Universelle des Mines*, Series 8, Vol. 7, Feb. 15, 1932, pages 292-302.

The results of metallurgical and micrographic tests on the influence of the flame in cutting steel is summed up as follows: The change of the steel in the neighborhood of the cut is in most cases very small, and often is even beneficial to its mechanical qualities. No special precautions need be taken for cutting ordinary steels with 40 to 60 kg./mm.^{2} and no further machining or other treatment is required if the cut by flame can be neatly made. Besides, if the flame-cut pieces are later to be joined by welding this process provides a sufficient heat treatment to eliminate any ill effect of the previous cutting. Ha (11c)

Recent Structures Wholly of Welded Steel. (Neuere vollständig geschweisste Stahlkonstruktionen.) F. Faltus. *Die Bautechnik*, Vol. 10, *Der Stahlbau*, Feb. 5, 1932, pages 23-24.

Discusses the advantages of welding structures. Tests were made on welded parts for resistance to wind pressure. The various methods of construction are enumerated. MAB (11c)

Comments on Automatic Arc Welding. A. F. Davis. *Metals & Alloys*, Vol. 3, Feb. 1932, pages 46-48.

The writer discusses the article by Candy in Nov. 1931. *Metals & Alloys*, on this subject and presents data on tensile tests of shielded arc welds. For abstract of paper see *Metals & Alloys*, Vol. 3, April 1932, page MA 100. WLC (11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Desulphurization of Thomas Pig Iron. (Ueber die Entschwefelung des Thomasroheisens.) Edgar Spetzler & Helmut Spitzer. *Stahl und Eisen*, Vol. 52, Mar. 10, 1932, pages 233-235.

Report 223 of Steel Mill Committee Verein deutscher Eisenhüttenleute. Includes discussion. Series of extensive practical tests with high-S Thomas pig iron, desulphurizing between blast-furnace and converter. Short supplemental tests consisted of adding calcined lime in pig iron ladle during casting, temporary shutting off mixer firing, and addition of "Walter" briquettes to converter ladle. (1.) Desulphurization on way from blast furnace to mixer. Calcined lime, 1 to 5 mm. pieces, was added to ladle runner in amounts irom 1.5 to 2.0 kg./ton pig iron over 4-day period.

Table 1.

	% Sulphur		Sulphur Decrease	
	Blast Furnace	Mixer	Actual	%
Pig iron—not treated	0.0777	0.0688	0.0089	11.5
(No. tests)	(143)	(143)		
Pig iron—treated	0.0830	0.0678	0.0152	18.3
(No. tests)	(149)	(149)		

(2.) Desulphurization in mixer. (a.) Calcined lime, 1.25 kg./ton, was added to mixer by shovelfuls.

Table 2-a

	Entering mixer	Leaving mixer	Decrease Actual	%
Mixer-not treated	0.067	0.065	0.002	3.0
(No. tests)	(105)	(72)		
Mixer-treated	0.068	0.059	0.009	13.0
(No. tests)	(105)	(72)		

Computation of mixer slag showed:

	% SiO_2	% CaO	% MnO	% S
Regular mixer slag	40.7	21.2	14.9	0.97
Treated mixer slag	35.7	30.2	12.4	1.27

(b.) During test run firing heat on mixer was shut off.

Table 2-b

	% Sulphur			
	Entering mixer	Leaving mixer	Difference Actual	%
Mixer heated	0.0656	0.0673	+ 0.0017	+ 2.6
(No. tests)	(36)	(55)		
Mixer not heated	0.0656	0.0557	— 0.0099	— 15.1
(No. tests)	(36)	(55)		

During this run, temperature loss without heat on mixer 60° C. and with heat on mixer 32° C. (3.) Desulphurization on way from mixer to converter. "Walter" foundry briquettes were added, 0.22% of pig iron weight, during filling of converter ladle, and after 10 min. reaction, slag was covered with calcined powdered lime. The S was decreased approx. 30% as against 6% without this treatment. Time factor and cost of briquettes, 1.60 R.M./ton, are too high for economy. DTR (12a)

Pitch Coke as a Carbonizing Agent in Steel Mill Operation. (Pechkoks als Kohlungmittel im Stahlwerksbetrieb.) L. Himpe. *Stahl und Eisen*, Vol. 52, Mar. 24, 1932, pages 295-296.

Pitch coke is found to be highly suitable for carbonizing steel. Has higher C-content and density, and gives less ash than either charcoal or petroleum coke. S in pitch coke is less than in petroleum coke, but higher than in charcoal. However its S gives no harmful effects to steel. Time for adding pitch coke to a charge is much less than for either charcoal or petroleum coke. Solubility is good. Decreased coke charges follow. DTR (12a)

The Production of Remelted and Guaranty Zinc Low in Iron. (Zur Herstellung von eisenarmen Remelted-und Garantiezink.) Wilhelm Hermann. *Chemiker-Zeitung*, Vol. 56, Feb. 17, 1932, pages 133-134.

In remelting Zn from scrap most of the Fe must be removed. The maximum allowed in remelted Zn is 0.25-0.30%. A reverberatory furnace with a deep hearth is preferable to one with a shallow hearth. In this type of furnace there is no contact with Fe and the bottom of the melt where the Pb settles is cooler than the rest of the melt. When melting in indirect fired iron melting pots the bottom of the melt is the hottest. The pots should be cast top up in order to secure a sound bottom and the rough surface should not be removed by machining. The addition of 2% Mn to the Fe is advantageous. A lime or graphite wash in the pot helps to prevent Fe from being absorbed by the Zn. Fe is removed by stirring S into the melt. For the removal of Pb the reverberatory furnace is better. CEM (12a)

Determines Inclusions in Steel by New Method. *Steel*, Vol. 88, Feb. 5, 1931, pages 57-58.

A resume of the research work on the physical chemistry of steel making carried out during the past year by the Pittsburgh Experiment Station, U. S. Bureau of Mines. Based on Bureau of Mines Report No. 3054. See "Fundamental and Applied Research on the Physical Chemistry of Steel Making." *Metals & Alloys*, Vol. 2, Feb. 1931, page 42. JN (12a)

The Behaviour of Manganese in the Acid Open-Hearth Process. E. Maurer & W. Bischof. *Iron & Steel Institute, Advance Copy* No. 12, May 1932, 30 pages.

From data obtained from several commercial melts the constant "K" in the following equation is obtained:

$$K = \frac{(Fe) : Mn}{(Mn)}$$

The quantities (Fe) and (Mn) give the corresponding weight concentrations of the slag, and the quantity Mn the Mn concentration of the metal bath .The dependence of "K" on the slag composition is determined, and the effects of temperature are estimated. Calculations using the values obtained are in good agreement with plant data. 15 references. JLG (12a)

Some Metallurgical Points on Acid Open-Hearth and Electric Steel for Castings. F. A. Melmoth. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Nov. 1931, pages 458-495.

Physical and microscopical comparisons were made of acid open-hearth and electric steels for castings of close chemical composition and given absolutely identical heat-treatment. See *Metals & Alloys*, Vol. 2, July 1931, page 134. CHL (12a)

Casting & Solidification (12b)

The Heterogeneity of a Sand-Cast Steel Ingot. A. Kuiz. *Iron & Steel Institute, Advance Copy* No. 10, May 1932, 10 pages.

Steel containing 0.35% C, 2.06% Ni, 0.35% Cr and 0.24% Mo was cast into a preheated sand mold. The greatest diameter of the ingot was 1.4 m., and the ingot proper was 2.2 m. high. The hot top was 1 m. high. The ingot was sectioned longitudinally, and the cavities observed. The pipe extended throughout 60% of the ingot plus hot top. Cavities 0.02 to 0.08 mm. wide were observed on the axial section. The structure was determined by etching and by S prints. The vertical segregations were broader and more pronounced than in chill-cast ingots. Drillings from various sections were analyzed. The highest and lowest values were:

	Ladle	Lowest	Highest
	%	%	%
C	0.35	0.27	0.48
Mn	0.59	0.56	0.63
Si	0.27	0.24	0.29
P	0.033	0.018	0.051
S	0.021	0.012	0.034
Ni	2.06	2.03	2.08
Cr	0.35	0.35	0.36
Mo	0.24	0.22	0.30

The sand-cast ingot was compared with chill-cast ingots previously studied. JLG (12b)

Centrifugal Casting of Non-Ferrous Metals. *Metal Industry*, N. Y., Vol. 29, Dec. 1931, page 516.

Taken from "Centrifugal Casting of Metals and Alloys" by J. E. Hurst, *Metals & Alloys*, Vol. 2, Oct. 1931, pages 196-205. For abstract see *Metals & Alloys*, Vol. 3, May 1932, page MA 136. PRK (12b)

The Melting and Casting of Magnesium Alloys. (Das Schmelzen und Giessen von Magnesiumlegierungen.) R. Thews. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Apr. 17, 1932, pages 165-167.

Utilize Pressure in Casting Brass. *Foundry*. Vol. 59, Dec. 1, 1931, page 49.

Die casting by the pressure method is being applied to brass die castings. The Titan Metal Mfg. Co., Bellefonte, Pa., has installed 3 brass die casting machines made by Josef Polak, Prague, Czecho-Slovakia. The American Brass Co. has installed 2 pressure brass die casting machines designed by Charles Pack and the Doehler Die Casting Co. is now installing 6 designed by their own engineers. VSP (12b)

Fourth Report of the Heterogeneity of Steel Ingots. A. Joint Committee of the Iron & Steel Institute and the National Federation of Iron & Steel Manufacturers to the Iron & Steel Industrial Research Council. *Iron & Steel Institute, Advance Copy*, May 1932, 204 pages.

Section I describes tests made on 27 ingots, most of which were cast in a standard 36-cwt. mold. Of these, 18 were killed steel and the remainder rimmed steel. The ingots were sectioned and the heterogeneity determined. The results of each test are described in detail and the mechanism of solidification is deduced from these and earlier tests. Section II gives the results of O analyses made by a H-reduction method. Chips were fused with a Sn-Sb alloy. The O given off as CO was determined by catalyzing the reaction to form CH_4 and H_2O and determining H_2O. Section III discusses silicates in steel, and gives results obtained by the Dickenson method. Section IV discusses the principles involved in making rimmed steel. Mechanisms by which rimming may be effected are suggested, but it is concluded that the exact action occurring during rimming is not known. A bibliography of 48 references on rimmed steel is appended. Section V is in reference to pyrometry as applied to liquid steel. From a series of laboratory and shop tests it is concluded that the disappearing filament pyrometer is more practicable than the polarizing pyrometer. The agreement between results obtained by means of the former instrument, however, was not especially good. It is suggested that more care should be exercised in selecting the filters used with optical pyrometers. Attempts to measure temperatures of liquid steel by thermocouples and other means were unsuccessful. Part 1 of Section VI, by J. G. Pearce and E. Morgan, gives the physical properties of some ingot-mold irons. The irons are high in C and contain large graphite flakes. They are pearlitic as cast. The composition changes during use. Part 2, of Section VI, by J. W. Donaldson, reports thermal conductivities of some ingot irons at temperatures up to 425° C. Section VI contains 23 references. Section VII, by N. M. H. Lightfoot gives "Some Further Mathematical Considerations Concerning the Cooling and Freezing of Steel Ingots." Estimations of the effects of a poorly conducting layer between the molten steel and the ingot mold and the effects due to separation of the ingot from the mold are included. Section VIII is a bibliography of 130 references. JLG (12b)

Castability Varied by 23 Foundry Conditions. Correspondence from A. Portevin. *Metal Progress*, Vol. 21, May 1932, pages 68-69.

The writer discusses 5 classes of factors influencing the castability of alloys. A spiral test casting is used to test the property of castability. Castability increases with the superheat and is inversely proportional to difference in temperature between mold and melting point. It varies inversely as the solidification range and depends upon the form of crystals. WLC (12b)

Highly Accurate Parts from Tin-Base Alloys. H. L. Spaunburg. *Product Engineering*, Vol. 3, Apr. 1932, page 160.

For small accurate parts Sn-Sb-Cu alloys are used for die-casting; the tensile strength runs as high as 10,000 lbs./in.^{2} with a Brinell hardness of 30. The best pouring temperature is 800° F. Intricate designs of parts with close tolerances can be produced, and the white non-tarnishing color often eliminates the need of plating. Ha (12b)

Construction and Operation of Casting Pits. (Bauart und Benutzung der Giessgrube.) Fr. Vogelsang. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Apr. 3, 1932, pages 137-139.

General discussion of points to be observed in constructing and operating casting pits. GN (12b)

makes good steel better

Today you must sell at lower costs, but satisfy the customer as well.

The real test of a casting is the quality of the finished product it turns out. It must stand up under its job—withstand unusual and unforeseen strains, stresses and overloads. The casting must have a smooth, uniform surface—finer structure—added toughness.

Ferro-Carbon Titanium reduces costs and yields a higher quality product. Titanium treatment is playing an important part in cost reduction and product improvement for many classes of steels. Titanium Engineers will gladly counsel with you.

Comments on Steel Works Metal Molds. (Einiges über Stahlwerkskokillen.) C. V. Meszoely. *Die Giesserei*, Vol. 19, Feb. 19, 1932, pages 61-66.

Proper construction of a metal (chill) mold is of great importance to its life; the relations of taper for ingot and taper of the walls to the length of the mold and to the thickness of walls and ingot are investigated. A table is given for the best practice of wall thickness as dependent on the weight of the ingot. The best material for these molds is a hematite iron of about 3.8 to 4.2% total C, 0.3 to 0.5% fixed C, graphite 3.2 to 3.9%, Si 2.2 to 2.5%, Mn max. 0.8%, P 0.09%, S 0.03%. The structure should show fine lamellae of pearlite with fairly much free ferrite, and the hardness should not be higher than 120 Brinell. A few other compositions are added which also give good results. New molds should be treated carefully until the inner stresses are eliminated; they should be preheated and, after use, cool slowly. If possible, molds should not be used too often in succession, it is preferable to let them cool between heats to be touched by hand. Also the place of the mold on the car should be changed every time if possible. Ha (12b)

The Castability of Alloys and its Relation to the Solidification Interval (Coulabilite des alliages. Relation avec l'intervalle de solidification). A. Portevin & P. Bastien. *Comptes Rendus*, Vol. 194, Mar. 7, 1932, pages 850-853.

In a previous article (*Comptes Rendus*, Vol. 194, Feb. 15, 1932, 599-601) the authors discuss at considerable length an expression for the castability of pure metals. In the present paper they describe the results of experiments in which a metal mold was again employed, but in which attention was directed to the relationship between the castability and the constitution of 2 systems of alloys—namely, Pb-Sb and Sb-Cd. 2 laws have issued as a result of their experiments—(1) the castability varies inversely with the solidification interval and (2) the castability depends upon the mode of solidification and is relatively greater when definite compounds are formed than when solid solutions are produced. The results prove once again, if this is necessary, the difference between fluidity and castability, of which fluidity is only a secondary factor. The 2 laws referred to allow of a correct interpretation of the castability curves of the Mg-Al and Mg-Cu alloys, which are particularly affected by oxidation and by the production of films of magnesia. The authors have studied the effect of remelting on these alloys and have found that the castability increases as a result of changes in chemical composition, then reaches a maximum, and finally diminishes, owing to the thickening of the alloy through the presence of oxides or nitrides. The article is accompanied by 2 diagrams, showing the relationship between the castability and the constitution of the two alloy systems, Pb-Sb and Sb-Cd. OWE (12b)

Steel; the Casting of the Ingot (L'acier; la Coulée de l'Ingot). Marcel Guédras. *Aciers Spéciaux, Métaux et Alliages*, Vol. 7, Mar. 1932, pages 99-101; Apr. 1932, pages 142-146.

Top and bottom pouring are discussed. The time required to cast a mold by using nozzles of different sizes was determined.

Diameter of nozzle	Speed of pouring in tons/minute
30 mm.	1.1 Tons
35 mm.	1.6 Tons
40 mm.	2.1 Tons
45 mm.	2.6 Tons
50 mm.	3.1 Tons
60 mm.	4.6 Tons

The ingots used for sheets and for forgings require a pouring of 900 kg./min. for C steel and 600 kg./min. for Ni steel. It is suggested that the cooling and the formation of an ingot take place in separate layers starting from outside toward the center. In practice it was found that the casting at high temperature produces a spongy cavity along the axis of the ingot. Schwartz treatment of hot top is also discussed as well as reheating the ingot top by means of electrodes to reduce the formation of pipe. GTM (12b)

Press Casting. Charles Pack. *Metals & Alloys*, Vol. 3, Feb. 1932, pages 29-37.

Editorial comment prefacing this paper mentions the wide use of die casting alloys and development work done and being done to brighten the dark side presented by Mr. Pack. 4 references. The history of casting metals is briefly recounted. Casting in metal molds may be divided into permanent mold and die casting methods in present commercial use. The permanent mold process employs a metal mold into which the molten metal is introduced by the pressure of gravity, the mold being separate and somewhat removed from the melting equipment. The product of this practice is somewhat superior in accuracy and properties to the ordinary sand castings. Die casting is conducted in 2 types of machines. One in which the metal runs by gravity into a cylinder from which it is forced by a plunger into the mold or die. The other or goose-neck machine employs air pressure to force the molten metal from a flask-shaped ladle into the die. In both of the above cases the die equipment is very close to the melting pot and consequently subject to temperature gradients which frequently result in misalignment. The goose-neck type of machine is capable of handling the Al base type which cannot be handled in the plunger type machine. The disadvantages of both these methods are the proximity of the die to the melting pot, contamination of the metal by Fe from the pot and in the case of the goose-neck machine the introduction of dross and hard spots into the castings. Both types are incapable of handling alloys of the best properties beside the dross, contamination and internal imperfections introduced by the nature of the process. Press-casting as it is being used in Europe and this country avoids the disadvantages of both die casting and retains the good points of both. The author describes several types of press-casting machines. This process is essentially a permanent mold removed from the melting equipment so that misalignments do not occur by reason of the heat of the molten metal pot and during the casting operation is subjected to pressure from a suitable press. In this type of machine greater pressures are obtainable and it is capable of handling higher melting metals. It is a forging process on molten metal. WLC (12b)

Rolling (12c)

Blooming Mill Rolls. J. H. Hitchcock. *Rolling Mill Journal*, Vol. 6, Jan. 1932, pages 27-29.

Formation of fire cracks is due to unequal temperatures of the surface and of the interior of the roll. Water cooling of the surface reduces the difference in temperature, thus limiting the extent of fire cracking. It has been found that the use of 0.85-2.70% Ni in the roll metal reduces the susceptibility to fire cracking. High Ni content is advantageous also in that less wear will occur in a given set of passes than with plain C steel. Chief disadvantage of high Ni content is that it gives the rolls a slippery surface and deprives them of the gripping qualities which are so essential. For these reasons blooming-mill rolls are provided with ragging. It is important that the grooves of all forms of ragging be shallow and well rounded rather than deep or sharp-cornered. Grooves should not be placed where the speeds of the bar and of the rolls are far from equal. Many roll designers prefer to use a double set of helical grooves for ragging, each set being cut at an angle of about 30° from the direction of the roll axis. MS (12c)

Copper-Wire Rolling Mills. (Kupferdraht-strassen.) Ch. Bernhoeft. *Zeitschrift für Metallkunde*, Vol. 24, Apr. 1932, pages 90-93.

An account of the practical details in the design of Cu-wire rolling mills. RFM (12c)

Continuous Rod Mill With Vertically Arranged Motors. (Kontinuierliche Drahtstrasse mit obenliegenden Motoren.) *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Mar. 20, 1932, page 153.

A new continuous rod mill is described, recently installed at the Duisburg Works of the "Vereinigte Stahlwerke." The arrangement of the finishing stands is most unique and a departure from the methods applied so far in rolling rods. The finishing train is composed of 2 parallel trains each of 4 subsequent stands. The rolls of the finishing train are either horizontally or vertically arranged, so that the driving motors are placed above the stand in the case of the vertical stands. This mill permits rolling bundles, 200 kg. in weight of a rod 4½ mm. in diameter (about #7 rod). That is the largest output possible. The new mill is claimed to offer the big advantage of rolling an absolutely round rod. GN (12c)

Problems and Organization of a Production Division in a Rolling Mill. (Aufgaben und Organisation eines Arbeitsbüros im Walzwerk.) Otto Beyer & Peter Zahn. *Stahl und Eisen*, Vol. 52, Feb. 25, 1932, pages 181-189.

Report 92 of Rolling Mill Committee and Report 55 of Committee on Economy of Operation of Verein deutscher Eisenhüttenleute. Includes discussion which deals, in addition to present article, with K. Wiecke's article published in *Stahl und Eisen*, Vol. 52, pages 77-84 (1932). Real defect of rolling mill organization in past was frequent appearance of disorder, insecurity and uncertainty in estimate of classes of materials, brands, sizes, etc. Chief problems of production division appear to be: (1) preliminary estimate of sizes, brands, shapes, etc.; (2) preparation of order; (3) preparation of work. Tasks of production section are all clearly illustrated and expedients employed to get results, such as cards, charts, etc. are described. Finally a general plan illustrates connection between order and production preparation. DTR (12c)

Rolling Industry Attends to Precision in Mill Control. *Steel*, Vol. 90, Jan. 4, 1932, page 158.

A résumé of the many applications of automatic control equipment met with in the various phases of modern rolling mill practice. JN (12c)

Leading and Return Guide Devices for Rod and Wire Mill Stands. (Umführungen und Rückführungsvorrichtungen an Stab-und Drahtstrassen.) Emil Kästel. *Stahl und Eisen*, Vol. 52, Mar. 24, 1932, pages 287-289.

Description and illustration of operation of leading and return guides for both roughing and finishing stands in rod and wire mills. Equipment manufactured by Firma Fried. Krupp Grusonwerk. Akt.-Ges. These guides not only automatically displace rollermen used for introducing rod into various mill passes, but they help to keep uniform drawing speed throughout a mill stand. Each stand, roughing and finishing, is made practically automatic and continuous. DTR (12c)

Resistance to Deformation and Flow of Metal in Rolling. Part III. Erich Siebel. *Rolling Mill Journal*, Vol. 5, May 1931, pages 363-368.

Abstract translation of a report of the Rolling Mill Committee of the German Iron and Steel Institute. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 270. The author compares his results on resistance to deformation with the work of J. Puppe and analyzes the data of E. Siebel on the spreading of hot rolled metal at various temperatures, and the data of A. Falk on the evaluation of spread tests. The causes of acceleration are discussed and a summary of the author's studies are given in detail. JN (12c)

Shaping in the Plastic State. (Die Formgebung im bildsamen Zustand.) E. Siebel. Verlag Stahleisen, Düsseldorf, 1932. Cloth, 8½x12 inches, 91 pages. Price 12 RM.

The theoretical foundations for the plastic deformation of metals by hot and cold-working are discussed. Mathematical formulae and geometrical representations of stress distribution are worked out. Much of the data has been published before, this volume being a general summary. The mechanism of deformation in rolling, drawing, extrusion, punching, deep drawing and tube rolling is discussed in detail.

The questions of energy required for deformation and of energy losses in the various operations, of rate of deformation and of the formation of internal cracks, are all given general discussion. The importance of lubrication of the material being worked is brought out in several connections.

So mathematical a treatise cannot be adequately abstracted. Much more emphasis has been put on the subject of this treatise in Germany than elsewhere. The references cited are, roughly, 100 in German, 4 in French and 1 in English. H. W. Gillett (12c)-B-

Roll Pass Design. Part XXVII. W. Trinks. *Rolling Mill Journal,* Vol. 5, Mar. 1931, pages 181-186, 189-190.

In rolling billets or semi-finished bars, straightness and absence of seams and cracks are all important. Billets are rolled on 3-high mills, on the roughing rolls of bar mills, and on continuous mills. The author illustrates and describes 3 types of 3-high billet mills and gives complete tables of data on rolls, passes and working characteristics of each. These mills differ from blooming mills in that more than one bar is rolled at a time. In one example, the passes are rolled alternately; in the other, 2; the passes are rolled one above the other. Continuous mills are best suited for the mass production of billets. For small production, billet rolls are usually of the diamond or gothic type. The author illustrates the design of the gothic pass, describes its construction, and discusses its theory, special features, applications, precautions and limitations. JN (12c)

Roll Pass Design. Part XXIX. W. Trinks. *Rolling Mill Journal,* Vol. 5, May 1931, pages 341-346.

Large finished squares, 1" to 4" on a side, are rolled in hand mills. Each pass is a roughing pass, a leader, and also a finishing pass. The bar is finished in any given pass by being passed through 2 or 3 times, with 90° turns between passes. The bar is finished slightly octagonal but contracts on cooling to a perfect square. This method is used only with short billets for small reductions at low rolling speeds. Another method, for larger production, employs a separate finishing stand and obtains greater reductions in the roughing roll. Slabs are rolled from semi-finished squares on the universal slabbing mill or on high-lift blooming mills. These require no roll design or only a very small amount other than the computation of the desired initial square section. JN (12c)

Roll Pass Design. Part XXX. W. Trinks. *Rolling Mill Journal,* Vol. 5, June 1931, pages 415-418.

A discussion of the 4 methods of rolling flat sheets. For average work, the use of continuous mills with edging rolls between the main stands is quite common. The flat and edging method of rolling uses stepped rolls and is applicable to flats of intermediate widths. Tongue and groove rolling is practiced where very close adherence to dimensions and uniformly clean, sharp edges are required. This method is used also for thin, wide flats such as sheet bars and hoops. Rolling on the diagonal corresponds to the method of rolling squares and is confined to flats having a side ratio of not over 2:1. This method is commonly used for tool steel. Wide flats are rolled on continuous mills with vertical edging rolls or by tongue and groove methods. JN (12c)

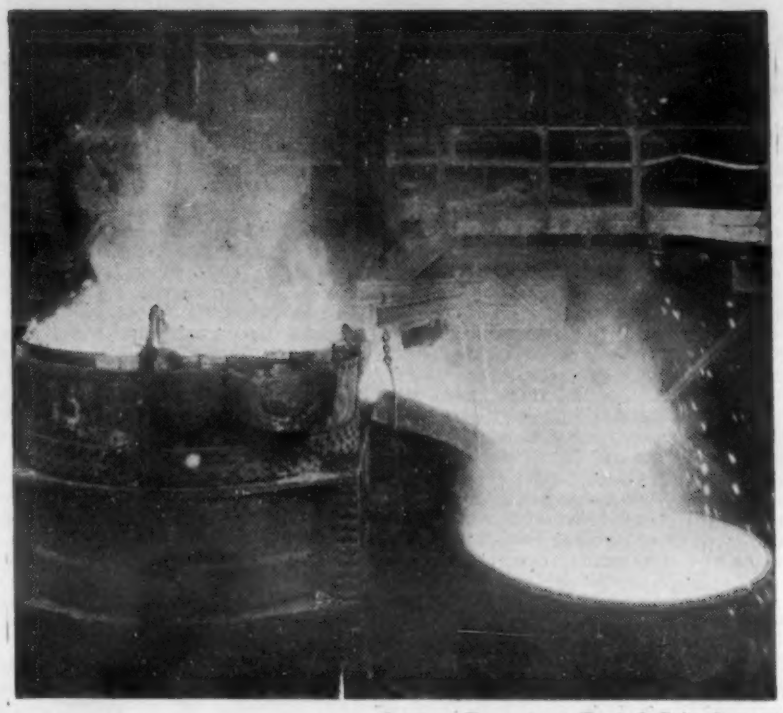
Roll Pass Design. W. Trinks. *Rolling Mill Journal,* Vol. 5, Aug. 1931, pages 535-538; Sept. 1931, pages 595-598; Oct. 1931, pages 655-658; Nov. 1931, pages 715-718, 745; Dec. 1931, pages 775-778, 792.

Methods of rolling hexagons, rounds and angles are discussed in these installments and the dimensioning of rolls for definite purposes explained. The factors to be observed in rolling of angles with unequal legs and of channels are also discussed. Ha (12c)

Electric Power is Regenerated by New Roll Train Drag. Arthur J. Whitcomb. *Steel,* Vol. 89, Oct. 12, 1931, pages 31-33.

See "Electric Regenerative Drag for Sheet Mills," *Metals & Alloys,* Vol. 3, May 1932, page MA 136. Ha (12c)

The Twin-Motor Drive for Main Rolls. H. H. Wright & H. E. Stokes. *Rolling Mill Journal,* Vol. 5, June 1931, pages 403-406.



An abstract of a paper delivered before the Association of Iron and Steel Electrical Engineers, Cleveland, O., week of June 15. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 74. The electrical and mechanical arrangements of the twin motor drives for a 54" blooming mill and a 44" slabbing mill are described in detail and the advantages of the twin-motor drive for reversing service in wide strip mills are discussed. JN (12c)

Sheet and Tin Mill Developments during 1931. R. J. Wean. *Rolling Mill Journal,* Vol. 6, Jan. 1932, pages 25-26.

Improvements have been made in the design of mill tables used in connection with the "Combination System" of sheet and tin mills. To enable the sheets to be delivered substantially flatwise from the catcher to the feeder, the tilt point was placed at the extreme end. The tables are symmentrical about the center line of the mill, so that operators can work on either side of the mill. There is no chance of interference with other auxiliary equipment. MS (12c)

Production of Spring Wire from Soft Ingot Steel. (Herstellung von Springfederdraht aus weichem Flussstahl.) Hans Wiesecke. *Stahl und Eisen,* Vol. 52, May 5, 1932, pages 433-439.

This class of wire originally was called water-tempered or "Water wire" and the chief difficulty in its production in the past was that the product did not run uniform. A low C-steel, 0.055% C and 0.57% Mn, is recommended for obtaining a uniformly tempered product. Mn, which may be a trifle higher with still lower C, is a favorable addition. Increased amount of hardening may be obtained with rise of C to 0.12%, but a decrease in Mn with 0.12% C-steel is a necessity. Differences in hardening temperature, inasmuch as this lies above the A_3 point, are not appreciably altered by rate of cooling. In the cold drawing process physical properties of the wire are similarly affected, either from an original tempered or soft condition. The widely respected view that open-hearth steel is not suitable for producing good spring wire has been shown to be erroneous. Uneven tempering may be kept within limits, but not entirely eliminated. Placing a whole reel of wire into cooling water is an advantage and tends towards uniform and even temper throughout. Variations in strength of product may be lowered to a minimum by careful supervision, uniform furnace, rolling, and cooling water temperatures. Finishing temperature and rate of cooling vary with different wire sizes. Diameter of wire, ready for finish draw after tempering, should run from 5.3 to 6.5 mm. with tensile strength from 55 to 72 kg./mm.^{2} Diameter of product should be 3.8 mm. after cold roll reduction in 3 dies, with tensile strength of 95 to 110 kg./mm.^{2} Operating procedure in 8 mills includes data on chemical composition of suitable steel, both Thomas and open-hearth, type of reel, tempering temperature, water temperature. 27 references. DEFECTS (13)

Failures of Thin-Walled Tubes. (Fehler bei dünnwandigen Rohren infolge Herstellung oder Weiterverarbeitung.) W. Ridde. *Die Röhrenindustrie*, Vol. 24, Jan. 1, 1931, pages 1-3; Jan. 15 1931, pages 15-16.

Describes how to reveal by metallographic investigation the manufacturing method of mild steel and low alloy steel tubular products. The difference between the seamless and welded tubes is mainly based on the detection of the seam and of P and S segregations respectively. If segregations are shifted into the weld due to shearing and sizing measures, failures in service are most likely to occur. Further violations of manufacturing rules are discovered by the occurrence of Fe_3C at the grain boundaries, indicating overannealing. Pipe holes may be detected by magnetic methods. Slag and other non-metallic inclusions and the appearance of segregation lines are readily discovered under the microscope. Mistakes during the further manufacturing processes refer to faulty threading of thin-walled tubes and to defective material from the dip-solder process. The use of higher C steel larger cross-sections and a temperature below 1050° C. are urged to prevent failures. The release of internal stresses before soldering should be insured. Welding is inferior to soldering in regard to vibration strength due to the properties of a casting of the first and the favorable thermal treatment of the latter joining method. EF (13)

The Production of Ferrous and Non-Ferrous Castings for High-Class Internal-Combustion Engines. S. White. *Foundry Trade Journal*, Vol. 46, Mar. 17, 1932, pages 176, 179.

A general paper on the above subject, in which reference is made to troubles occasioned by the presence of cuprous oxide in main bearing castings. OWE (13)

Transverse Fissure Statistics. W. C. Barnes. Appendix C-2 to report of Rail Committee, *Bulletin American Railway Engineering Association*, Vol. 33, Feb. 1932, pages 567-572.

The trend of actual rail failures in track from transverse fissures has ceased to rise, being checked by the use of heavier rail sections, decrease in traffic and by the removal of rails found by the "Detector" cars to be in process of fissuring, before they actually fail. In 11 months of 1930 reported on, 5277 fissure failures occurred on the lines reporting, and 1434 were detected and removed before failure. Failures to the end of 1930 in the rollings of 1923 to 1927 show for all mills, an average of 4.54 fissure failures per year per 100 track miles, with one mill down to 0.43 and two mills up to 10.7 and 11.1. Correcting these by a factor for traffic density the average failures per year per unit of traffic density, still range from 0.43 to 10.2, for different mills with the average at 2.91. HWG (13)

Cores as Causes of Failure. (Wichtiges über Kerne als Ausschussursache.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Mar. 6, 1932, pages 104-105.

Cores cause failures of castings when they contain an excessive amount of binding material. It is shown in a few practical examples that failures were apparent when the above condition had not been fulfilled. GN (13)

Nature of Abnormal Grain Growth in High Speed Steel. G. R. Brophy & R. H. Harrington. *Transactions American Society for Steel Treating*, Vol. 19, Mar. 1932, pages 385-402.

Non-Metallic Inclusions in Steel. J. C. Booth. *Journal Institute of Fuel*, Vol. 5, Feb. 1932, page 216.

Outline of the origin and effect of inclusions. There are 2 classes which command attention, oxides and sulphides, the oxides, which include the silicates, being the most important. Majority of inclusions found in ordinary commercial C steels are the products of deoxidation, the usual deoxidizers being ferromanganese and ferrosilicon. Mn is incapable of completely deoxidizing steel and if a killed steel is desired Si must be added. With low-C steels it is almost impossible to kill the steel and keep it clean. For this reason, deep drawing sheet steel is only semi-killed or not even killed at all. Very little definite information is available regarding the effect of inclusions on physical properties. They are not harmful in all cases. Free-cutting laminated spring steel and Aston wrought iron are examples of their deliberate introduction. Steel required for high duty must be reasonably free from inclusions. MS (13)

A New Type of Inclusion in Cast Iron and Its Relation to Manganese and Silicon Content. F. J. Cook. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Oct. 1931, pages 423-439.

Brittle Fracture in Ductile Steels. B. P. Haigh. *Iron & Steel Industry & British Foundryman*, Vol. 5, Nov. 1931, pages 53-54.

A single theory is presented to explain the occurrence of a brittle fracture in ductile steel. CHL (13)

Taking Care of Inclusions in Steel. C. H. Herty, Jr. *Iron Age*, Vol. 128, Dec. 17, 1931, pages 1573-1574.

An abstract of the 6th Campbell Memorial Lecture read before the American Society for Steel Treating at Boston. See "Non-Metallic Inclusions in Steel," *Metals & Alloys*, Vol. 3, June 1932, page MA 181. VSP (13)

An Interesting Swelling Phenomenon in an Aluminum Alloy. (Eine interessante Treiberscheinung bei einer Aluminiumlegierung.) O. Gregor. *Mitteilungen des Technischen Versuchsamtes in Wien*, Vol. 20, Nos. 1-4, 1931, pages 36-39.

A remarkable destruction was observed in a cube and a piece of Al sheet, both of the composition Al 55%, Zn 45%. Pb traces. After 9 years of storage they showed splitting and spalling. (13)

Bubbles and Pores in Metals and Welds. (Ueber Blasen und Poren in Metallen und Schweissen.) H. A. Horn & K. Tewes. *Autogene Metallbearbeitung*, Vol. 25, Mar. 15, 1932, pages 88-92.

Pores and hollow spaces are in most cases caused by the manufacture of the metal; air and other gases are enclosed and not fully removed. The different possibilities, influence of freezing velocity of the metal, chemical reactions, and in welding the electrode and the arc or the kind of gas used are discussed and the means for detection of pores are briefly described. Ha (13)

Forging Defects in Twist Drills. (Schmiedefehler an Schlangenbohrern.) R. Meebold. *Glückauf*, Vol. 68, Apr. 2, 1932, pages 319-322.

Life of twist drills depends chiefly on proper choice of material, kind of shaping and heat treatment. Highly carburized tool steel of average analysis 0.7% C, 0.22% Si, 0.2% Mn, less than 0.04% P, less than 0.04% S, less than 0.07% P+S, is used. This material, thoroughly annealed, has tensile strength of 70 to 85 kg./mm.² with minimum elongation of $\delta_{10} = 13\%$. Crystal structure should be fine grained and finely laminated pearlitic. In practice breaks occur in 3 main places of the drill: Position 1, at the square shank end inserted in chuck and directly below the band; Position 2, at shank end where the spiral is forced on the core; 3, in the center of the length of the drill. Samples of all types of defects were examined in the cable testing section of the Westphal Mine Laboratories. Sections were made and the drills fractured at defective points and examined. Breaks at 1 are called "tinges," a defect due to imperfect forging. Around the tinge there is heavy decarburization, which is attributed to oxidizing action of hammer scale. The hammer scale is closed up in the tinge in the form of slag. At position 3 breaks are apparently made during swaging. Utmost care in the forging process will avoid the defects. DTR+Ha (13)

Cracks and Defects in Wheel Rims. (Ueber Brüche an Radreifen.) Alfred Pohl. *Stahl und Eisen*, Vol. 52, June 2, 1932, pages 539-542.

In the unusually severe winter of 1928-1929 the wheel rims of locomotives and tenders on the Austrian railroads showed a large number of cracks. The problem was to determine if these cracks were a result of decrease in toughness of the steel at the low temperatures encountered. Tests of 8 broken rims showed 7 with tensile strength higher than 85 kg./mm.² and notch toughness with the usual average value for steel used for the same purpose. Examination of structure showed the cracks to lie along the boundaries of the transcrystallization dendrite zones or to be due to gas blow holes. The rather strong dendritic formation and gas holes appeared to be the sole causes, while the low temperatures were of almost no influence in causing the cracks, except for the amount of decrease in toughness coincident with the low temperatures encountered. DTR (13)

Technical Defects in Pipe Lines. (Technische Mängel im Rohrleitungswesen.) K. Gabler. *Die Schmelzschweissung*, Vol. 11, Apr. 1932, pages 72-74.

The author repudiates the accusations made by another writer that the great losses sometimes experienced in gas lines have to be charged to welded pipe lines and enumerates a number of probable other sources of losses. If welds in pipe lines are made conscientiously they are among the most reliable joints. Ha (13)

Failures of Axles of Railway Cars. (Achsbrüche von Eisenbahnfahrzeugen und ihre Ursachen.) R. Kühnel. *Glasers Annalen*, Vol. 110, Feb. 15, 1932, pages 29-37; Mar. 1, 1932, pages 41-52.

Includes discussion. Most comprehensive investigations and observations by the German Federal Railway System on the failures of axles are reported. The number of the failures of axles is very low. GN (13)

The Cause of the Porosity of Cast Iron. (Die Ursache der Porosität von Gusseisen.) A. Jaeschke. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Feb. 21, 1932, pages 79-80.

The author deals with 2 different types of porosity: (1) porosity due to holes, and (2) sponginess. The first type of porosity is caused by gases. Porosity can be caused by an unsuitable composition of the cast iron and improper casting temperatures. GN (13)

Overcoming Shatter Cracks in Rail Manufacture. I. C. Mackie. *Canadian Chemistry & Metallurgy*, Vol. 16, May 1932, pages 141-142.

"Shatter cracks" may be fully eliminated by retarding cooling in the "black heat" range. They take place at comparatively low temperatures, the most dangerous at about 250° C. The hardness is unimpaired. The rails are kept in the cooling boxes until the temperature is within 30° C. of the outside atmospheric temperature. The time required for the slow cooling is usually about 24-30 hours. WHB (13)

Investigation of Cracking of 42 mm. Steel Rounds. J. Prochorow & A. Brahuta. *Domez* (Achievements of Metallurgy in USSR and Abroad), No. 9, 1931, pages 1-33. (In Russian.)

In making 0.20-0.40 C quality steel, scrap losses in the finished product amounted to 40-50% largely due to seams and cracks. Blooming mill losses were exceptionally high on account of ingots tearing between the rolls. Steel was made in 50 ton basic open-hearth furnaces. Investigation showed that the loss was connected with poorly conducted melting operation, defective roll design and improperly conducted rolling operation. Metallographic investigation indicated that most of the troubles were due to the rolling. By issuing detailed instructions for melting and teeming (given in the paper), redesigning the rolls and standardizing rolling practice the losses were reduced to normal. (13)

Causes of Bursting of the Pipes in Water Tube Boilers. (Note sur un element d'information intéressant la recherche des causes d'éclatment des tubes de chaudières aquatubulaires.) A. Delacour. *Annales des Mines*, Thirteenth Series, Vol. 1, 1932, pages 337-349.

Examination of many cases of boiler failures due to bursting of water pipes showed that the area adjoining the failure was often in quenched state instead of being annealed as was the rest of the tube. The possibility of quenching of low C steel in boiling water was investigated by heating the specimens to high temperatures and quenching them in boiling water. Structures resembling those observed on boiler tube fractures were produced. Local overheating to above the upper critical point followed by quenching by the escaping steam and water was suggested as an explanation. JDG (13)

LUDWIG MOSER & HANS GRABER. *Monatshefte der Chemie,* Vol. 59, Jan. 1932, pages 61-72.

Contains 74 references. Separation of Rh from Pt: Dilute the weakly acid solution containing $RhCl_3$ and H_2PtCl_6 to 300-400 cc. and add 30 cc. M/2 $NaBrO_3$. Heat to 70° and add from a pipette M/1 NaBr. Boil for 1 hour. Precipitation is complete if no Br forms when more bromate-bromide solution is added. Filter, wash and ignite. Heat the residue 15 minutes in a stream of H_2, then cool in CO_2. Boil the residue in dilute HCl, filter, wash and ignite as before. Weigh Rh. Determine the Pt with hydrazine chlorohydrate. Rh from Au: Use the same method as for Pt, except dilute solution to 800 cc. Rh from Cu: To the 200 to 400 cc. solution add H_2SO_4 to make it N/10 and $MgCl_2$ so that it contains 15 cc. M/10 $MgCl_2$ per 100 cc. solution. Heat to near boiling and pass in H_2S until it cools. Filter, wash and ignite. Treat the residue with 1:1 HNO_3 for 1 hour, decant and filter. Ignite the oxides, reduce them in H_2 and cool in CO_2. Leach out Cu twice with conc. HNO_3 and filter off Rh and wash. Ignite the residue, heat in H_2 and cool in CO_2. Wash with H_2O and weigh Rh. Determine the Cu in the filtrate electrolytically. Rh from Fe: To the 200 to 400 cc. solution containing the chlorides add HCl until it is N/7 to N/10. For every 100 cc. solution add 15 cc. M/10 $MgCl_2$, heat to boiling and pass H_2S through until the solution is cold. Filter, wash and determine Rh as before. Boil out H_2S from filtrate, oxidize the Fe and determine by double precipitation with NH_4OH. Rh from Pb: Add H_2SO_4 to the solution contained in a porcelain dish and evaporate to fumes. No reddish brown $Rh_2(SO_4)_3$ should form. Dilute and decant through a Gooch crucible. Add 2 N H_2SO_4 to the precipitate and allow to stand for several hours. Decant and filter through the Gooch crucible and wash with 96% alcohol. Ignite at a dull red heat and weigh $PbSO_4$. Evaporate the filtrate almost to dryness and determine Rh by the sulphide method.

Micro-Chemical Methods in Metallurgy. (Mikrochemische Methoden in der Metallkunde.) M. NIESSNER. *Die Metallbörse,* Vol. 21, June 27, 1931, page 1206.

Methods are discussed for detecting traces in metals and alloys by micro-chemical work referring to Ni, Co, Cu + Ni, Cu + Ni + Co, S and P segregations, and non-metallic inclusions. Paper before the 68th General Meeting of the Deutsche Bunsengesellschaft für angewandte physikalische Chemie, Vienna, 1931. EF (14)

The Quantitative Micro-Analytical Determination of Carbon and Hydrogen. (Ueber die quantitative mikroanalytische Bestimmung des Kohlenstoffes und Wasserstoffs.) A. FRIEDRICH. *Die Metallbörse,* Vol. 21, Aug. 12, 1931, page 1518.

A new laboratory equipment for the micro-determination of H_2 and C in an O_2 current was developed including: absorption apparatus according to Pregl except stop cocks, flow meter as a substitute for the previously used pressure regulator and a U-tube instead of a bubble counter. The Mariott bottle is also abandoned. Paper at the 36th General Meeting of the Verein Deutscher Chemiker, 1931. EF (14)

Solid Gold Hydride. (Festes Goldhydrid.) E. PIETSCH & E. JOSEPHY. *Die Naturwissenschaften,* Vol. 19, Aug. 28, 1931, page 737.

Solid Au hydride was secured by treating pure Au (1000/1000) with atomic hydrogen. Chemical detection is given. EF (14)

Application of Optical Spectroscopy to the Determination of Heavy Elements in Tissue. WINIFRED MANKIN. *Chemical Engineering & Mining Review,* Vol. 24, Jan. 5, 1931, pages 142-144.

A series of experiments are described that are aimed to obtain a complete analysis of the heavy elements of tissue. An arc circuit was found to be most satisfactory to obtain an emission spectrum for the work. WHB (14)

Analysis of Oxygen in Steel. Correspondence from A. PORTEVIN. *Metal Progress,* Vol. 21, Apr. 1932, pages 73-75.

The 2 methods most favored by the writer for the determination of O_2 in steel are by reduction with monoxide in vacuo with carbon, and by determination of alumina and silica after volatilization with chlorine. WLC (14)

Determination of Arsenic in Iron Ores, Melts and Steels. (Déterminatlon de l'Arsenic dans les Minerais de Fer, Fontes, et Acièrs.) C. MISSON. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 194-195.

The method used is based on the precipitation of As by reduction by means of sodium thiosulphate, redissolving the precipitate of As obtained, and finally weighing the product which is ammonium arseno-molybdate. MAB (14)

Standard Methods for the Sampling and Analyzing of Aluminum and Certain Aluminum Alloys. Aluminum Research Institute, 1932, 24 pages.

Loose leaf instruction book for determining Cu, Fe, Pb, Mg, Mn, Ni, Si, Sn and Zn in Al. (14)-B-

Determination of Molybdenum in Vanadium Steels. (Dosage du Molybdène dans les Acièrs Renfermant du Vanadium.) EDMOND ROUSSEAU. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 188-193.

The author concludes that if in place of using NaOH one uses Na_2CO_3 to separate Fe with Mo and V, the solution is easily diluted; all the V remains with the Fe and the Mo completely passes into solution and can then be determined correctly by a usual method. The method used for precipitation and ignition of the precipitate of Pb molybdate always gave correct results. The colorimetric determination of Mo, based on the more or less white coloration produced in a cold, dilute solution by the colloidal precipitate of Pb molybdate, permits the correct determination of very small quantities of Mo in steel, even in the presence of relatively large quantities of V. The procedure of separation described is superior to most others since it permits. (1) separation of Mo in the presence of V; (2) control of the purity of the final products, $PbMoO_4$ and MoO_3; (3) separate determination of the 2 metals in the same operation. MAB (14)

The Iodometric Determination of Chromium and Its Separation from Iron and Nickel. (Beiträge zur jodometrischen Bestimmung des Chroms und Trennung desselben vom Eisen und Nickel.) E. SCHULEK & A. DOZSA. *Zeitschrift für analytische Chemie,* Vol. 86, No. 1-4, 1931, pages 81-82.

1 To 20 cc. of cold Cr^{+++} solution add 2-5 cc. of freshly saturated Br water and 10 cc. of 30% NaOH. Heat until the solution begins to boil and then remove the flame. This suffices to accomplish complete oxidation of the Cr^{+++} to CrO_4^{--}; further heating might cause BrO_3^- to form. To the well-cooled solution add 5 cc. of 5% phenol solution to remove the excess Br_2. Transfer to an Erlenmeyer flask which is provided with a tightly fitting stopper and dilute to 400 cc. Add 4 g. of $KHCO_3$ and 25 cc. of 50% H_2SO_4 in small portions, watching to see if the greenish yellow color of the solution assumes a reddish tinge. Unless care is taken in this acidification, there is sometimes a little Br_2 formed by 2 the reaction between CrO_4^{--} and Br^- and the liberated Br_2 will react with the phenol present. Add 2 g. KI and any remaining portion of H_2SO_4. After 5 min. titrate the liberated I_2 with 0.1 *N* $Ha_2S_2O_3$. If Fe is present it is best to filter off the $Fe(OH)_3$ precipitate, dissolve it in acid and treat the resulting solution with NaOH and Br_2 again. Sometimes even a third treatment is necessary. If only a little Fe is present, it can be disregarded. When Ni is present, there is danger of Br being converted into BrO_3^-, so that after the removal of the $Ni(OH)_3$ precipitate it is necessary to make the solution strongly acid with H_2SO_4, boil 3 to decompose any BrO_3^- and then repeat the treatment with Br_2 and NaOH. The results of numerous experiments are tabulated; they indicate that this oxidation with Br_2 is better than the treatment with H_2O_2 so often employed.
Ha (14)

Simultaneous Determination of Sulphur and Carbon in Steel. (Gleichzeitige Bestimmung von Schwefel und Kohlenstoff im Stahl.) ADOLF SEUTHE. *Stahl und Eisen,* Vol. 52, May 5, 1932, pages 445-446.

Apparatus illustrated and described for making rapid and simultaneous volumetric analysis of S and O in steel. Accuracy of C determinations is same as by other similar 4 methods and that of S determination is of the order ± 0.002%. DTR (14)

Lithium Chloroplatinate and the Separation of Potassium from Sodium and Lithium by the Unmodified Original Fresenius Method. G. FREDERICK SMITH & A. C. SHEAD. *Journal American Chemical Society,* Vol. 53, Mar. 1931, pages 947-957.

The preparation of Li chloroplatinate suitable for a reagent in the precipitation of potassium is described. Potassium chloroplatinate is precipitated if the above reagent is used in place of chloroplatinic acid, with 80% ethyl alcohol as solvent. This precipitate is stable at 200°-260° C. MEH (14)

5 **The Selenious Acid Method for the Determination of Zirconium.** STEPHEN G. SIMPSON & WALTER C. SCHUMB. *Journal American Chemical Society,* Vol. 53, Mar. 1931, pages 921-933.

Zr is quantitatively precipitated as basic selenite by excess selenious acid from solutions, the acidity of which should not be greater than 0.6 *N*. The method is given in detail with procedure for the treatment of other metals commonly found in a Zr mineral. It gives satisfactory results even when all of such elements as Th, ceric Ce, Ti, V, Fe and U are originally present. A rapid method for decomposing Zr ores preparatory to making the analysis, is also given. MEH (14)

6 **Determination of Minute Quantities of Mercury and Its Significance. (Die Bestimmung kleinster Quecksilbermengen und ihre Bedeutung.)** A. STOCK. *Die Naturwissenschaften,* Vol. 19, June 5, 1931, pages 499-502.

The effect of Hg traces on the organism and detection of 10^{-8} g. Hg by colorimetric methods. Several determinations were made on laboratory reagents, foodstuffs, organic matter, etc. The absorption of spilled Hg by active charcoal soaked with I is recommended. EF (14)

7 **Colored Reaction of Molybdenum. Application to the Colorimetric Determination of Molybdenum in Steels. (Reaction Coloree du Molybdene. Application au Dosage Colorimetrique du Molybdene dans les Aciers.)** ERNEST BERTRAND. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, page 198.

The principle involved is as follows: if one adds a solution of $SnCl_2$ to a HCl solution of Mo containing W, which is held in solution by means of H_3PO_4, one obtains a color varying from light blue to deep violet-blue according to the quantity of Mo present. The specific technic as applied to determination of Mo is given fully. If V is present, it must be removed before making the Mo reaction. The method detects as little as 0.01 mg. Mo (which equals 1 part in 8 8,000,000). MAB (14)

Spectroscope Permits Rapid Estimation of Alloying Elements in Steel. *Steel,* Vol. 90, Jan. 18, 1932, page 31.

The Spekker Steeloscope is a special type of spectroscope developed by Adam Hilger, Ltd. for the rapid estimation of alloying elements in steel. An electric arc is set up between the specimen to be examined and an iron rod. The light rays from this arc are then resolved into their spectral lines by a system of prisms and the presence and relative proportions of other elements present with the iron estimated by visual inspection and comparison of the spectral 9 lines with a series of reference diagrams. It is possible to determine Ni, Cr, Mo, Mn, Ti, W, Co, Cu, Sn, Cd and V to an accuracy of 0.5%. JN (14)

Rapid Iodometric Determination of Copper in Antifriction Alloys. (Dosage Rapide du Cuivre dans les Allinges Antrifriction par Iodometrie.) E. BERTRAND. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, page 199.

The determination of Cu in antifriction alloys by the iodometric method is based on the principle that I freed by the action of Cu on KI, under conditions determined by the acidity, is titrated by a hypo-sulphite solution to which 10 one adds a slight excess. This excess is titrated back by a solution of I in the presence of starch paste. MAB (14)

A Method for the Determination of Cobalt in Magnet and High-Speed Steels. JAMES I. HOFFMANN. *Bureau of Standards Journal of Research,* Vol. 8, May 1932, pages 659-668.

A method for the accurate determination of Co in steel is described. WAT (14)

On Electrometric Titration. (Über die elektrometrische Titration.) *Die Metallbörse,* Vol. 22, Feb. 3, 1932, pages 145-146; Feb. 10, 1932, pages 177-178.

Outlines the present state of the electrometric titration, discusses the underlying principles, describes the methods of analyses with particular reference to the determination of metals, and urges wider adoption in commercial laboratories due to its remarkable potentiality. 14 references. EF (14)

The Analysis of Residues of Alloy Steels by Chlorination. (Lässt sich die Rückstandsanalyze durch Chloraufschluss auf legierte Stahlsorten anwenden?) R. Wasmuht. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen,* Vol. 11, 1932, 5 pages.

Determination of Iron Oxide in Liquid Steel. C. H. Herty, Jr., Hyman Freeman & M. W. Lightner. *Report of Investigations* No. 3166, *United States Bureau of Mines,* Apr. 1932, 10 pages.

Al is added to steel in a test spoon, the killed steel poured into a suitable mold, and the metal analyzed for Al_2O_3, from which the FeO in the steel may be calculated. When the metal has been deoxidized with Mn or Si, the SiO_2 is reduced by Al to about 0.006%, and it would be expected that almost all of the MnO would be reduced. The true FeO content is therefore not determined. If these inclusions are extracted electrolytically, it is possible to correct for SiO_2 and MnO. All slag must be removed from the surface of the steel in the spoon, as otherwise Mn and P are reduced. Slag used to coat the spoon has no effect. See also *Metals & Alloys,* Vol. 1, June 1930, page 568. AHE (14)

The Spectrographic Assay of Gold, Platinum and Silver, and of the Ores Containing the Same. *Mining Journal,* Vol. 177, Apr. 2, 1932, page 218.

A brief review of the literature. AHE (14)

The Determination of Zinc by Electrometric Titration. (Dosage Electro-titrimétrique du Zinc.) Edm. Leclerc. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 169-172.

The author comes to the conclusions that if the electro-titrimetric determination of Zn as he conducted the test, gives correct results in spite of the fact that ammonium salts in a solution of Zn are present, it is because he used 2 electrodes, both of which change color when different equilibria occur. He measured the true intensity of the current resulting from the difference in potential between the electrodes, being sure that the current stopped at the end of the test. This method reduces the chances for error to a minimum because of the rapidity with which it can be carried out. MAB (14)

Investigations on the Determination of Tungsten by Gravimetric and Volumetric Methods. (Recherches sur le Dosage du Tungstene par Voie Gravimétrique et Titrimétrique.) George Dotreppe. *Chimie et Industrie,* Vol. 25, Special Number, Mar. 1931, pages 173-178.

Reduction of tungstic acid by Zn and HCl did not give a composition derived from trivalent W. The products obtained corresponded to a complex oxide, W_4O_7, of which no trace has been found in the literature. The author is uncertain whether or not it is a combination of the two oxides, W_2O_3 and W_2O_4. In either case, the method described for determining W by titration gives very satisfactory results, and, moreover, permits the determination of W in the presence of phosphates which is hardly possible by gravimetric methods. MAB (14)

Separation of Cadmium from Zinc by H_2S. Leo Baumeister. *Chemist-Analyst,* Vol. 21, May 1932, pages 7-8.

Precipitation of CdS is easier from solutions containing H_2SO_4 than HCl and can be hastened by addition of a little NH_4OH as a starter. Red CdS is precipitated when H_2S is passed slowly in fairly acid, hot solutions. It filters rapidly and is to be preferred for fairly large amounts of Cd. Yellow CdS is precipitated when H_2S is passed rapidly in cold, weakly acid solutions. It is finely divided and filters slowly, but comes down fast and is preferable when the Cd content is low. A concentration of 4 cc. H_2SO_4 in 100 cc. solution produces a complete separation of small amounts of Cd from large amounts of Zn, but if the Zn content is very high a double precipitation is necessary. It is most convenient to finish the Cd determination by electrolysis in a slightly alkaline solution containing a little KCN at 1 to 1.5 amps. on Cu plated Pt electrodes. CEM (14)

The Determination of Cadmium in Sulfide Zinc Ores. Archibald Craig. *Chemist-Analyst,* Vol. 21, May 1932, pages 8-11.

Occlusion of Cd by the residue insoluble in H_2SO_4 is prevented by this method and the correct conditions for H_2S precipitation are used. To a 10 g. sample add 100 cc. hot H_2O and 25 cc. HNO_3 in 3 portions, then 40 cc. 1:1 H_2SO_4. Evaporate to slight fumes, dilute to 350 cc. and boil gently for 1 hour. Add 10 g. $(NH_4)_2SO_4$ and pass in H_2S rapidly for 15 min. Filter and wash. Dissolve precipitate and paper in 10 cc. HNO_3 and 10 cc. H_2SO_4. Heat to fumes and add dropwise 1 to 5 cc. HNO_3. Continue heating with HNO_3 additions until organic matter is destroyed and HNO_3 expelled. Dilute, boil and filter. Repeat the acid treatment of the residue twice using 10 cc. H_2SO_4, combining the first two filtrates. Add to these 15 cc. NH_4OH and dilute to 300 cc. which should produce 4% acidity. To the third filtrate add 10 g. $(NH_4)_2SO_4$, dilute to 250 cc. and pass H_2S into both solutions. If no CdS is found in the third filtrate proceed with first two filtrates alone. Filter CdS and dissolve in 10 cc. H_2SO_4 and HNO_3 as before. Add 10 g. $(NH_4)_2SO_4$, dilute to 250 cc., pass in H_2S and filter. Test filtrate for Zn. Dissolve CdS as before, add an excess of NH_4OH and $(NH_4)_2CO_3$ and boil. Filter if necessary. Add a slight excess of NaCN to the filtrate and pass in H_2S. Let stand over night. Filter through pulp without washing. Dissolve the CdS as before using 5 cc. H_2SO_4. Evaporate without boiling to remove all free H_2SO_4. Cool, dilute and add 1 g. NaCN. Electrolyze with .1 amp. with fixed electrodes for 2 hours. Wash in alcohol, dry and weigh Cd. CEM (14)

The Potentiometric Determination of Iridium. Sho-Chow Woo & Don M. Yost. *Journal American Chemical Society,* Vol. 53, Mar. 1931, pages 884-888.

The data show that the new titanous chloride titration method of determining iridium gives results in agreement with those given by the earlier iodometric method, which was refined by using benzene to detect the liberated iodine. The results of both methods are in agreement with the gravimetric. MEH (14)

Quantitative Spectral Analysis of Alloys. (Zur quantitativen Spektralanalyse von Legierungen.) H. Töpermann & W. Shuhknecht. *Zeitschrift für analytische Chemie,* Vol. 86, No. 1-4, 1931, pages 160-174.

2 simple contrivances are shown by means of which the picture of the logarithmic sector of the spectral lines is provided with marks so that the lines can be evaluated without other measurement. A wedge photometer is also described which is useful for evaluating spectrograms, and the reproducibility attainable is shown by a large number of measurements. The influence of various kinds of electrodes is discussed; electrodes with surfaces roughened by use require longer times of exposure than electrodes with polished surfaces. 20 references. Ha (14)

Quantitative Determination of Copper in the Acid Copper-Bath (Massanalytische Bestimmung des Kupfers im sauren Kupferbad). K. Altmannsberger. *Oberflächentechnik,* Vol. 8, Oct. 6, 1931, page 207.

An iodometric method and a method using Rh are described which require only 10 cc. of the solution. Both methods are very sensitive and take only a few minutes. Ha (14)

Quantitative Optical Spectral Analysis of Lead Alloys. (Quantitative optische Spektralanalyse von Bleilegierungen.) A. Guenther. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 200, Oct. 14, 1931, pages 409-418.

Homologous pairs of spectral lines were determined for the systems Li, Cu, Zn, Au, Te and Bi in Pb and also of Ag in Sn which can be very well used for optical determination. Tables of the numerical values are added. Ha (14)

On Micro Chemistry. (Über Mikrochemie.) F. Emich. *Die Metallbörse,* Vol. 21, Aug. 12, 1931, page 1517.

The speaker before the Verein Deutscher Chemiker, 1931, aims at 2 goals: (1) to give a bird's eye view of the evolution and present state of micro-chemical determinations and (2) to focus attention on some problems which need further research work along micro-chemical lines. EF (14)

Problems of Quantitative Chemical Spectral Analysis. (Aufgaben der quantitativen chemischen Spektralanalyse.) W. Gerlach. *Die Naturwissenschaften,* Vol. 19, Jan. 9, 1931, pages 25-28.

The significance of the spectral analysis is stressed when only minute quantities of the sample are available and when contaminations are present at extremely low concentrations, so that chemical analysis fails. After outlining the underlying principles of the method, the writer discusses the limits of detection which do not only depend on the light intensities but also on the kind of light excitation. The limit is given to be around 1/1000 atomic %. The minimum amount of the sample requisite for spectral analysis depends on several factors and amounts to 10^{-7} to 10^{-9} g. in case of electro-deposited metals. A special chapter takes up the problem of "local analysis" and describes the investigation of Au, Ag and Pt material of wearing industry, in which Pt-metals, contaminations from hard solders and crucibles could be proved. Analysis of refractory linings revealed Mg, Sr, Ca and appreciable amounts of V. Pb up to 0.04% renders Au brittle due to the occurrence of a brittle Au-Pb compound at the grain boundaries. Cu + Ag additions result in an accumulation of Cu + Pb at grain boundaries. The testing of metals in a highly pure state by spectral analysis is emphasized in the next chapter. The absence of Fe was proved in pure Cu, Au and Ag, but was never insured in Pt although being distributed very irregularly. The detection of Bi in Pb for storage batteries goes as far as 10^{-4} atomic %. The investigation of Pt metals showed their relative impure state and the examination of pure Ni disclosed the presence of C. The chemical analysis of a Ag sample stated its absolute purity, but spectral analysis revealed traces of Au, Si, Sn, Zn and Th. Furthermore the spectral analysis furnishes a means of checking deviations of atomic weight determinations. The investigation of Ca showed the presence of appreciable amounts of Sr. A special chapter is devoted to the detection of Hg. Traces of this metal are either electro-deposited on Sn or chemically precipitated with Cu artificially added. In the deposition and precipitant quantities as low as 7×10^{-8} g. of Hg can be detected. EF (14)

Determination of Tin in Tin Pyrites in the Presence of Cassiterite. (Bestimmung von Zinn im Zinnkies bei gleichzeitigem Vorhandensein von Cassiterit.) Bruno Hirsch. *Chemiker-Zeitung,* Vol. 56, Feb. 13, 1932, page 127.

3 methods are given. (1) Fuse 1 g. sample with Na_2O_2 and dissolve melt in HCl. Reduce the Sn with Fe or Ni, filter and titrate with standard iodine solution. The result gives the total Sn content. To another 1 g. sample add 10-15 cc. 63% HNO_3, boil and add 30 cc. 38% HCl. Warm for 1 minute and dilute with 50 cc. hot H_2O. Filter and wash 4 times with hot 5% HCl. Ignite and fuse the residue with Na_2O_2 and finish the same as the first sample. This result gives the Sn present as cassiterite. (2) To the filtrate from the second sample in the first method add an excess of NH_4OH, filter, wash and ignite. This result gives the Sn present as tin pyrites. (3) To a 1 g. sample add 10 cc. HNO_3 and evaporate to dryness. Cool and add 10 cc. of a solution consisting of 2 g. Br and 100 cc. 30% HCl. Evaporate to dryness and warm with 50 cc. 30% HCl. Dilute to 250 cc. and add 1 g. of pure Fe and 2 Swedish horseshoe nails. Boil for 30 minutes, cool without filtering and titrate with standard iodine solution. This result gives Sn present as tin pyrites. CEM (14)

HISTORICAL & BIOGRAPHICAL (15)

Michael Faradny Actually Made Stainless Steel. ARTHUR LAMSLEY. *Heat Treating & Forging*, Vol. 17, Dec. 1931, pages 1105-1106.

At the recent Michael Faraday Centenary Celebrations in London, Sir Robert A. Hadfield presented results of his investigation of the steels and alloys made by Faraday during 1819 to 1824. These establish beyond doubt that Faraday is the pioneer of alloy steels. Sir Robert was given permission to examine the contents of a box stored in the basement of the Royal Institution. The box was labelled "Steel and Alloys" and contained 79 specimens, having a total weight of 7 lb. 14 oz. Analysis of these specimens showed presence of Cr, Cu, Au, Ni, Pt, Rh, and Ag. Pd was found in a specimen lent by the Science Museum, London. Some of the alloys were of low C content, *e.g.* 0.16, 0.12, 0.10, and 0.07% C. Physical tests were also made. These indicated that Pt to a slight extent, and Ni and Au to a more marked degree, improve the tensile properties of C steel, while Rh affected them adversely. MS (15)

Three Centuries of German Metal Plastic Art. (Deutsche Metallplastik aus drei Jahrhunderten.) WILHELM PINDER. *Stahl und Eisen*, Vol. 52, Mar. 17, 1932, pages 257-262.

Historical sketch of German metal plastics in 16th, 17th and 18th centuries with illustrations representative of various periods. Trend in Germany from beginning of plastic work has always been towards use of metals. DTR (15)

Early Chemistry and Chemists in the Iron and Steel Industries of America. L. W. SPRING & L. E. GILMORE. *Metals & Alloys*, Vol. 3, Feb. 1932, pages 40-42.

The authors sketch the history and personalities of the development of the iron and steel industry and its chemistry. WLC (15)

Early Babylonian Jewelry. SIDNEY SMITH. *Brass World*, Vol. 28, June 1932, pages 115-116.

Babylonian metal workers did interesting and intricate metal casting and forming as far back as 3500 B. C. WHB (15)

Collecting and Filing of Corrosion Literature. (Sammlung und Sichtung der Korrosionsliteratur.) W. WIEDERHOLT. *Korrosion und Metallschutz*, Vol. 8, Feb. 1932, pages 35-46.

This paper before the Reichsausschuss für Metallschutz 1931, furnishes directions on efficient filing methods of the extensive corrosion literature, the information on which is partly scattered in text-books, theses, patents and partly among reports and publications under all kinds of head lines. In 1929 for instance, 55 books, dissertations, etc., 1900 original articles in 333 domestic and foreign magazines and 572 international patents were filed in a subject and author index. It is estimated, that in summary 25,000 publications on the subject are available at the present time. The necessity for convenient filing is evident. The speaker suggests the use of a filing method which includes an author and a subject index on differently sized cards. Patents should be filed by numbers and not alphabetically according to the inventor. The speaker's proposals on the subject index are based on the following classification: (1) Corrosion A) material, 1) metals, 2) non-metallic materials. B) corrosion media 1) chemical reagents, 2) commercial fields. (II) Corrosion Protection A) General, C) surface treatment, D) additions to the liquid medium (inhibitors), C) additions to the alloys or material, D) impregnations, E) electrolytic protection, F) special methods. (III) Miscellaneous, A) Notion conception "corrosion," B) economic and commercial questions, C) statistics, D) books, E) reports of societies, F) trade names. Based on experiences gained on surveying the corrosion literature during a long period of time, further subdivisions (up to five) of the three main groups are discussed and presented in detail. One of a series of historical sketches on "Chemistry in Canada." WHB (15)

The International Material Testing Congress in Zurich, 1931, and the Development of Material Testing up to the Present. (Der Internationale Materialprüfungskongress in Zürich 1931 und die bisherige Entwicklung der Materialprüfung.) OTTO HOENIGSBERG. *Mitteilungen des technischen Versuchamtes in Wein*, Vol. 20, Nos. 1-4, 1931, pages 30-36.

An interesting historical review is given of the development of the arts and artisanship in metals; in olden times the craftsmen knew his material and its properties so well as to get the best performance in use and fine decorative effects. Systematic material testing dates from about Galileo, Mariotte, Reaumur and finally the scientific period beginning in the last quarter of the 19th century with Bach. The present status of the comparative importance of tests to which materials are subjected is discussed with special reference to the convention in Zurich. Ha (15)

Notes on a Research on Faraday's Steels and Alloys. ROBERT HADFIELD. *Engineering*, Vol. 132, Oct. 2, 1931, page 440.

Abstract of paper read before Section G of the British Association for the Advancement of Science, Sept. 24, 1931. See *Metals & Alloys*, Vol. 3, July 1932, page MA 221. LFM (15)

Origin of the Word Sonim. Correspondence from H. D. HIBBARD. *Metal Progress*, Vol. 21, Apr. 1932, page 68.

Writer explains the origin of the coined word "sonim" used as substitute for the cumbersome phrase "solid nonmetallic impurities." WLC (15)

Ancient Water Supplies. JAMES W. ARMSTRONG. *Water Works Engineering*, Vol. 85, Jan. 13, 1932, pages 18-20.

Interesting account of the water supplies and distribution systems of the ancient countries. Large quantities of lead pipe were used by the Romans. CBJ (15)

Some Bronze Specimens from the Royal Graves at Ur. C. F. ELAM. *Institute of Metals, Advance Copy* No. 589, Apr. 1932, 8 pages.

Bronze specimens which were probably made between 2600 and 3500 B.C. were examined. All contained small amounts of Ni, and some contained Sn. All specimens were covered with a heavy layer of corrosion products. There was an outer green layer, probably malachite, a layer of Cu_2O, and a black layer adjacent to the metal. The composition of the black layer could not be determined, although lines from the Cu_2O phase were observed in X-ray patterns from this material. Microstructures indicated that some of the specimens were in the cast condition, and that some of them were wrought. The wrought alloys were not as badly corroded as the cast. 3 references. JLG (15)

Brinell, Rockwell, Shore or Monotron Hardness? (Brinell, Rockwell, Shore oder Monotron Härte) E. IRION. *Die Metallbörse*, Vol. 21, May 2, 1931, pages 819-820; May 9, 1931, pages 867-869.

The historical review of the hardness testing methods refers to the contributions of Brinell, Ludwig, Shore, Wüst and Bardenheuer, Baumann, Rockwell, Martens, Vickers, Herbert, Morin and Poldihütte, Schwarz. EF (15)

History and Developments in the Art of Welding Ferrous Metals. A. J. MOSES. *Combustion*, Vol. 3, Feb. 1932, pages 38-44; Mar. 1932, pages 26-30; Apr. 1932, pages 28-33; May 1932, pages 7-14.

A series of articles in 4 parts dealing with welding art. In Part I the author reviews the history of welding and begins discussion of the forge welding process with hammer welding. Part II continues the forge welding discussion with roll and resistance welding. Fusion welding is begun in the last section of Part II, and is concluded in Parts III and IV. The writer is an authority on the subject, especially in the field of fusion work and has made extensive studies in the history of the art. A diagrammatic classification is given of the principal welding processes. All welding process techniques are described and their application, pros and cons indicated. Chapters on acetylene process, carbon arc and metallic arc welding are through. The most important factor in obtaining deposited metal of desired properties in electric-arc work appears to be the shielding and protection of the arc and the liquid pool of metal against all harmful gases. The best results have been obtained by the use of the socalled heavily covered electrodes. The author gives a practical and intimate turn to his discussion of pressure vessel application by telling of the experiences and practice of his own organization, a pioneer in this branch of the art. DTR (15)

The Development of the World's Lead and Zinc Production from 1907-1928. (Die Entwicklung der Blei- und Zinkerzeugung der Welt von 1907-1928.) F. SCHULTZ. *Internationale Bergwirtschaft und Bergtechnik*, Vol. 24, Mar. 30, 1931, pages 79-87; Apr. 15, 1931, pages 93-96; Apr. 30, 1931, pages 113-115; May 15, 1931, pages 124-128; May 30, 1931, pages 134-137.

This historical review bears the sub-title: "An investigation of the technical and economical evolution of Pb and Zn mining, with special reference to the influence of improvements regarding mining, ore dressing and smelting methods." The different continents are discussed separately. A summary in German, English and French is included. EF (15)

Old Brass Plants in the Upper Drau Valley. (Die bestandenen Messingwerke des oberen Drautales.) R. CANAVAL. *Montanistische Rundschau*, Vol. 34, Aug. 1, 1932, pages 1-9.

Interesting outline of the history of the century old existence of brass producing plants in the Drau valley, Austria. 16 references. GN (15)

Technical Education and Training. JOHN ORR. *Transactions South African Institute of Electrical Engineering*, Vol. 23, Apr. 1932, pages 77-145.

An historical review of the work during the past 23 years of the technical schools of South Africa. WHB (15)

The Development of the Electro-Pig Iron, Steel, and Cast Steel Production. (Die bisherige Entwicklung der Elektro-Roheisen-, Stahl- und Stahlgusserzeugung.) E. KOTHNY. *Elektrowärme*, Vol. 2, July 1932, pages 160-163.

A complete review shows the development since its inception of the production of Fe and steel in electric furnaces in the different countries, their share in the world production, where and when it was first introduced, type of furnace and kind of product. The statistics cover the time from 1906 to 1930 and give also some indication what price can be paid for electric energy in order to make the electric process competitive with other fuels. Particular application has been made of the electric furnace in the field of special steels and small steel castings. Ha (15)

Aluminum and Its Metallurgical and Commercial Prospects. ROBERT P. TOD. *Metal Industry*, London, Vol. 40, Jan. 15, 1932 pages 63-68.

The history of the development of Al is discussed. PRK (15)

Properties of Some Si-Mn Steels. (Eigenschaften einiger Silizium-Manganstähle.) *Die Metallbörse*, Vol. 22, May 14, 1932, page 611.

A literature review of properties of Si-Mn structural steels with emphasis on recent statements of Burns. EF (15)

Note on the Early History of Rust Protection. (Aus der Kindheit des Rostschutzes.) O. VOGEL. *Korrosion und Metallschutz*, Vol. 8, Apr. 1932, pages 91-92.

Gives some early references (1786) on the corrosion resistant Fe of Bernard & de Canclers, Paris. EF (15)

Old and New Welded Ornamental Work. (Alte und Neue geschweisste Kunstschmiedearbeiten). HERMANN RICHTER. *Autogene Metallbearbeitung*, Vol. 25, May 1, 1932, pages 129-134.

An historical review of the development of ornamental arts in iron which spread from the Roman empire and Greece to other countries. A number of typical examples of the art and their working methods are described. Ha (15)

ECONOMIC (16)

Molybdenum Industry in 1931—Advance Summary. P. M. Tyler & H. W. Davis. *United States Bureau of Mines, Mineral Market Reports* No. M.M.S. 102, Apr. 7, 1932, 2 pages.

Domestic mine production in 1931 was approximately 3000 short tons of Mo concentrates containing 5,221,000 lb. (average 85.93%) MoS_2. Shipments of an equivalent of 3,157,000 lb. Mo were valued at $1,577,000. In 1930 production was 3618 short tons of concentrate containing 6,205,000 lb. (average 85.75%) MoS_2. Shipments in 1930 were equivalent to 3,759,269 lb. Mo, worth $2,068,000. The principal depelopment of the yr. was the rapid increase in the use of Mo in cast Fe. Uses are discussed. 3 companies, 2 in the U. S., produce 97-98% of the world's Mo. AHE (16)

The European and World Zinc Situation. O. W. Roskill. *Advance Paper, American Zinc Institute,* Apr. 1932, 11 pages.

The trend of production during the last decade, the causes of increased production, due to improved processes and greater prospecting activity, the trend of consumption, prices and production cost, plans for regulating production and consumption, tariff bills in different countries, and the galvanizing industries are reviewed. The need for intensive research to meet the growing competition of various non-ferrous metals and alloys for the same purpose as Zn is emphasized, particularly outside America. Ha (16)

The Costs of Converting Scrap of Aluminum, Brass, Red Brass and Bronze into New Ingot Metal. (Die Kosten einer Umarbeitung von Aluminium-, Messing-, Rotguss-und Bronzeabfällen zu neuwertigem Blockmetall.) H. Reininger. *Die Giesserei,* Vol. 19, Jan. 22, 1932, pages 28-29.

It is pointed out that in all plants where continually large amounts of scrap materials are produced it is more profitable to convert them into new ingot material than to sell them as scrap. Comparative data are tabulated. Ha (16)

Four Man-Hours of Direct Labor in Ton of Open-Hearth Steel. *Steel,* Vol. 90, Jan. 4, 1932, page 138.

It requires 4.14 man-hrs. of direct labor to produce one gross ton of open-hearth steel using 55% scrap. It requires 5.88 man-hrs. to produce one ton of pig iron and 7.38 man-hrs. to produce one ton of steel if no scrap is used. JN (16)

One Has to Discount the Lessons of Tikhvinaluminostroy. Tourkin. *Light Alloys,* Feb. 1932, pages 7-9. (In Russian.)

The activities of this organization controlling and operating bauxite mines supplying the country with alumina were a failure on account of the disorganization and stealing. The production reported as 115% actually was only 20%. (16)

At Leningrad Aluminostroy. A. P. Serebrowsky. *Light Metals,* Feb. 1932, pages 5-7. (In Russian.)

Utter disorganization at Volkhov aluminum plant badly interferes with its completion. (16)

The Austrian Iron, Metal and Machinery Industry in 1931. (Die österreichische Eisen-, Metall- und Maschinenindustrie im Jahre 1931.) *Tägliche Montanberichte,* Supplement to *Montanistische Rundschau,* Vol. 24, Mar. 16, 1932, pages 1-5.

Annual Report on the Austrian steel business in 1931. GN (16)

Mercury Exports in 1931—Advance Summary. *United States Bureau of Mines Mineral Market Reports* No. M.M.S. 108, Apr. 26, 1932, 2 pages.

In 1931 the U. S. exported 4984 flasks of Hg valued at $433,596. Figures are given by countries. AHE (16)

United States' Lead in World Production Cut. *Steel,* Vol. 90, Jan. 4, 1932, pages 148-149.

The World's production of iron and steel continued to decline during 1931, falling to 68,662,000 gross tons of steel ingots and castings as compared to 92,877,000 tons in 1930 and 117,980,000 tons in 1929, and dropping to 55,312,000 gross tons of pig iron as compared to 78,485,000 tons in 1930 and 96,729,000 tons in 1929. Although maintaining its leadership, the U. S. produced only 37% of the world's output of steel in 1931 as against 43% in 1930 and only 33% of all pig iron as against 40% in 1930. The per capita consumption of steel in the U. S. dropped to 4.61 lbs. in 1931. JN (16)

Steelmaking Capacity Added in 1931 Unparalleled in Past 13 Years. *Steel,* Vol. 90, Jan. 4, 1932, pages 171-173.

A discussion of the steel making equipment completed or in process of construction in the United States during 1931. This includes the following installations.

	Completed in 1931	Incomplete Dec. 31, 1931
By-Product coke ovens	68	138
Stacks remodeled	6	3
Open-hearth furnaces	34	0
Rolling Mills	33	21

10 blast furnaces were dismantled in 1931. JN (16)

Foundries Study Markets in Low Production Period. *Steel.* Vol. 90, Jan. 4, 1932, pages 166-167.

In spite of poor demand and low prices, the steel foundry industry was busily engaged during 1931 in developing new lines, exploring new markets, studying new uses for castings, and otherwise preparing for new business when economic conditions should improve. Production costs were lowered by the introduction of short cuts in manufacture, improvements in heat treating and manufacturing methods, the reduction of waste, and the wider use of scientific metallurgical control of foundry operations. The gray iron and malleable iron industries also weathered the depression, improving their manufacturing methods, contributing their respective research institutes, and adding to the number of electric melting furnaces. JN (16)

More Iron and Steel Than Iron Ore. *Steel.* Vol. 90, Jan. 4, 1932, pages 143-145.

During 1931, the production of iron and steel exceeded the total production of iron ore. During the past 20 years steel production increased 36%, pig-iron and ferro-alloys increased 10%, while iron ore production decreased 3%. The increased use of scrap and improvements in furnace practice have conserved over 14 million tons of ore during the past 5 years. However, it is believed that the proportion of scrap has reached its maximum and that future steel demands will call for greater ore production. JN (16)

Estimation of Small Castings. (Kalkulation von kleinen Gussstücken.) Werner Weck. *Die Giesserei,* Vol. 19, Mar. 4, 1932, pages 91-92.

A few examples are given to show that small castings are often offered for too low a price; the actual amount of molten Fe used should be figured and the correct piece price and overhead included to arrive at the exact cost. Ha (16)

Production Economy in Iron and Steel Works. Part II. Cost of Production. O. Cromberg. *Engineering,* Vol. 132, Oct. 16, 1931, pages 484-485.

See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 76. LFM (16)

New Methods of Calculating the Cost of Production in Steel Foundries. (Neue Formen der Selbstenrechnung in Stahlgiessereien.) O. Cromberg. *Archiv für Eisenhüttenwesen,* Vol. 5, July 1931, pages 63-70.

The author describes a new system of calculating the production cost in steel foundries and shows that by determining the characteristic, "Kennzahlen," of the plant its economy can be simply supervised, and the price of the product is easy to find. The usual practice in cost finding in foundries has been to take the productive wages as the basis of calculation. This method is refuted and it is recommended that "wage-time" should be taken as basis. The new calculating method is illustrated by examples and figures. GN (16)

Building Retains Lead in Steel Consumption. Automotive Industry Passes Railroads as Second Largest Consumer. *Steel,* Vol. 90, Jan. 4, 1932, pages 131-133.

The annual survey of finished rolled steel distribution shows a greatly decreased consumption for 1931. This is estimated at 17,956,582 gross tons as against 28,686,600 gross tons for 1930. The consumption of steel in 1931 was distributed as follows: Building industry, 16.80%; automotive industry, 14.78%; railroads, 14.65%; oil, gas and water, 9.75%; highway construction, 2.35%; food packing industries, 7.90%; mining and lumbering, 0.83%; shipbuilding 1.03% and machinery, tools and equipment, 3.37%. JN (16)

Steel Fights to Loosen Grip of Depression. *Steel,* Vol. 90, Jan. 4, 1932, pages 150-151, 153.

The low prices and low consumption of steel in 1931 are seen as resulting from decreases in building construction, automobile output, freight traffic and the manufacture of steel products and fabricated steelwork. The steel industry is seeking to meet this condition by reductions in wages and economies in operation, management, etc. JN (16)

Gold, Silver, Copper, Lead and Zinc in Nevada in 1930. V. C. Heikes. *United States Bureau of Mines, Mineral Resources of the United States,* 1930, Part I, May 20, 1932, pages 515-554.

The total value of the mine production of Au, Ag, Cu, Pb and Zn from Nevada mines in 1930 was $21,455,517, a decrease of $11,574,720 from 1929. Au output decreased from 163,711.22 to 149,064.47 oz., Ag from 4,923,526 to 4,219,832 oz., and Cu from 140,138,809 to 109,203,512 lbs. (22% decrease in amount and 42% in value). Pb production increased from 19,692,568 to 23,058,311 lbs. and Zn from 16,920,083 to 29,168,117 lbs., exceeded only by 1916. AHE (16)

Magnesium Industry in 1931—Advance Summary. A. E. Davis. *United States Bureau of Mines, Mineral Market Reports* No. M.M.S. 107, Apr. 14, 1932, 2 pages.

In 1931, 580,463 lbs. of Mg ingot worth $199,633 were sold or used, an increase of 3.7% in quantity and a decrease of 26% in value from 1930. Domestic Mg was all obtained from $MgCl_2$ at Midland, Mich. Sales of Mg alloys, castings, powder, wire and ribbon, rod and tubing, sheet, etc. are detailed for 1929, 1930 and 1931. AHE (16)

Iron and Steel Industry in 1931—Advance Summary. H. W. Davis. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 113, May 26, 1932, 5 pages.

The production of steel decreased from 40,699,483 gross tons in 1930 to about 25,600,000 tons in 1931. Pig Fe production (exclusive of ferro-alloys) declined 42% from 1930 to an output of 17,952,613 gross tons in which was used 29,286,653 gross tons of domestic Fe ore and manganiferous Fe ore, 1,231,587 tons of foreign Fe ore and manganiferous Fe ore, and 3,127,099 tons of cinder, scale and scrap, an average of 1.874 tons of metalliferous materials per ton of pig Fe (1.939 in 1930). Production of ferro-alloys (466,969 tons) declined 36% from 1930. 1931 production of ferro-Mn was 166,937 gross tons containing about 131,200 tons of Mn (78.59%), in which was used 287,973 gross tons of foreign Mn ore, 10,945 tons of foreign ferruginous ore, 12,277 tons of domestic Mn ore, 8,269 tons of Fe ore and 3,405 tons of cinder, scale and scrap, a total of 1.799 tons of ore per ton of ferro-Mn (1.792 in 1930). Production of ferro W was 847 tons (79.15% Fe) and of ferro V was 373 tons (37.19% V). Fe ore mined was 31,131,502 gross tons, a decrease of 47% from 1930. AHE (16)

Secondary Metals in 1930. J. P. Dunlop. *Mineral Resources of the United States, United States Bureau of Mines,* 1930, Part I, Dec. 31, 1931, pages 333-354.

The total decrease in quantity of the secondary metals covered in this inquiry was 24% in 1930, compared with an increase of 7% in 1929. Production for 1929 and 1930, respectively, were Cu 417,600, 332,800; brass 298,500, 192,000; Pb metal 138,500, 129,000; Pb in alloys 172,500, 126,800; Zn metal 65,400, 49,300; Zn in alloys other than brass 11,600, 7,700; Sn metal 7,400, 5,600; Sn in alloys and chemical compounds 26,900, 20,600; Sb 11,131, 8,082; Al metal 25,850, 19,700; Al in alloys 22,550, 18,900; Ni metal 850, 500, and Ni in alloys and salts 3,500, 2,400 short tons, 913,382 tons worth $193,255,100 as compared with 1,202,281 tons worth $331,028,900. In 1930, 47,316 oz. of Pt, 34% of imports, was recovered, 4,557 oz. more than in 1929. Mints and refineries recovered 6,472,713 oz. of Ag and $22,189,966 in Au from waste. AHE (16)

Lead and Zinc Pigments and Zinc Salts Industry in 1931—Advance Summary. H. M. Meyer. *United States Bureau of Mines, Mineral Market Reports* No. M.M.S. 120, June 8, 1932, 2 pages.

Decreases in Pb pigment sales in 1931 were as follows: red Pb, 22%; orange, 21%; basic Pb sulphate, 16%; litharge, 12%; and white Pb, dry and in oil, 5% each. ZnO sales declined 20%, lithopone 7% and $ZnSO_4$ 15%. Sales of leaded ZnO were 8% higher than in 1930 and of $ZnCl_2$ 20% higher. Figures are given for consumption by uses. AHE (16)

MISCELLANEOUS (20)

Experiments on Impact. J. P. Andrews. *Proceeding Physical Society*, London. Vol. 43, Pt. 1, Jan. 1, 1931, pages 8-17.

This paper, which describes the continuation of a research on the impact of soft metallic bodies, contains the results of 4 investigations, as follows: (1) Impact of equal spheres for low values of the velocity of approach v. The duration of contact is found to vary inversely as $v^{1/5}$, whilst the coefficients of restitution e in the same cases are found to be unity for all speeds below a value characteristic of each material, as though the metals were perfectly elastic for smaller speeds. (2) The effect of duration of contact on the size of the permanent deformations. No effect was observed. (3) the variation of duration of contact t with mass of sphere at high speeds of approach. Within the limits of experimental error, t varies as the square root of the mass, as theory predicts. (4) The impact of crossed cylinders. No important new phenomena are found. Ha (20)

The Physics of High Pressures. P. W. Bridgman. G. Bell & Sons, Ltd., London, 1931. Cloth, 5¾ x 9 inches, 390 pages. Price 22s.6d.

When a man has worked 25 years in a well defined field and published some 73 papers on that field, it is time to write a book about it. The need of a good book on high pressure phenomena and Professor Bridgman's qualifications for writing it are well known. The word "Physics" in the title is to be interpreted in its broadest sense, for the book covers many types of changes which may be produced by using pressure as an independent variable. We find, for example, chapters not only on the P-V-T relations in fluids and the compressibility of solids, but also on melting phenomena, polymorphic transitions, electrical resistance, thermoelectric properties, thermal conductivity and viscosity. The treatment of these subjects is mostly a description of the experimental method used and the results obtained. Mathematical theory is largely absent except for simple thermodynamics which is unusually powerful in this field. Extremely valuable are the chapters on the general technique of the production and measurement of high pressures. The author ascribes his success to his method of leakless packing of pipe connections and pistons.

(page 35) "The principle of unsupported area . . . (of packing) . . . is the only thing that has made possible my own high pressure work."

(page 78) "The whole high pressure field opened almost at once before me, like a vision of a promised land with the discovery of the unsupported area principle of packing, by which the only limit to the pressures attainable was set by the metal parts of the apparatus."

For high pressure pump cylinders he uses an electric furnace chromium-vanadium steel of typical analysis—Cr 0.93, Mn 0.68, C 0.51, Si 0.23, Va 0.18, S 0.010, P 0.008. This is hardened and drawn to a Brinell hardness of 400. Plungers are of glass hard ball bearing steel, which by careful axial loading have withstood 750,000 lbs./in.^{2} in compression. It is shown that under the conditions imposed by hydraulic pressure in a hollow cylinder neither the tensile strength or elongation are criterions of rupture, for such material will withstand stresses and elongations several times those of the tensile test. Furthermore, rupture begins from the outside where stress and elongation are a minimum. Except under special conditions glycerine and water or kerosine are used to transmit the pressure. Pressures of over 40,000 kg./in.^{2} are mentioned, though for most of the data 12,000 kg. is the maximum. The working standard of pressure measurement is the change in resistance of a manganin coil. The photograph (facing page 44) of a typical pressure installation will delight those who believe that the proper place for fine workmanship is in the working parts of an apparatus, and that electric wiring can be done without the aid of a licensed electrician and metal conduit. Though dealing largely with the work of the author, adequate mention of previous investigators is given. The index is poor, giving mostly authors' names. H. W. Russell (20)-B-

Straightening Damaged Parts of Steel Cars. *Transit Journal*, Vol. 76, Apr. 1932, pages 179-181.

Methods used, some of an ingenious nature, in repairing collision damages. CBJ (20)

Analysis of Accident Causes in the Metals Industry. C. P. Waite. *Heat Treating & Forging*, Vol. 18, Feb. 1932, pages 104-106.

Paper read before the Annual Safety Congress, Oct. 31, 1931. Cites examples of accidents in metal-working plants to show how true causes may be determined by ascertaining the manner in which the workman was doing his work at the time of the accident, and why he was doing it that way. MS (20)

The Principles of Electrical Gas Purification. (Die Grundlagen der elektrischen Gasreinigung.) R. Strigel. *Die Naturwissenschaften*, Vol. 19, July 17, 1931, pages 626-634.

The principles underlying the electrical dust and fume precipitation according to Cottrel-Möller is fully discussed with respect to (1) the corona discharge phenomenon, (2) the charge of the suspended particles, (a) theoretical considerations, (b) experimental results, (3) the effect of the electrical wind, (4) the mechanism of the precipitation. 44 references. LABORATORY APPARATUS (21)

New Equipment for Metallographic and Mechanical Laboratories. K. F. Starodoubof. *Domez* (Achievements of Metallurgy in USSR and Abroad), No. 10, 1931, pages 47-60.

A review of foreign instrument exhibition in Leningrad in 1931. The exhibits were furnished principally by German firms though a few U. S. manufacturers of metallographic and testing equipment were represented. (21)

A High-Temperature Electric Furnace and a Micro Adaptation. R. C. Emmons. *Science*, Vol. 73, May 8, 1931, pages 499-500.

A very cheap and practical home-made furnace with nichrome-wire heating elements for temperatures up to 1000° C. is described; also a resistance furnace made of arc-lamp C for temperatures up to 2300°. The latter may be modified by drilling a hole in the side of the rod to hold the sample and placing on a transite board on a microscope stage to observe the fusion. Ha (21)

Two Novel Methods for the Unequivocal Indexing of Convergency Photograms. (Zwei neue Methoden zur eindeutingen Indizierung von Konvergenzaufnahmen.) O. Kratky (Kaiser Wilhelm Institut für Faserstoffchemie, Berlin-Dahlem). *Zeitschrift für Kristallographie*, Vol. 76, Feb. 1931, pages 517-524.

Two methods are developed for the unequivocal indexing of X-ray photograms in which crystal and film are stationary. Manifold directions of the incidenting X-ray beam are secured by the utilization of a "flat convergency beam." A less accurate mounting of the crystal does not exert a material influence on the subsequent indexing. The first method outlined in the paper is simpler in regard to the experimental accomplishment than the second one. The graphical evaluation, for which a special apparatus was designed, takes more time for the second method. EF (21)

Rhodium Wire for Laboratory Furnaces. (Rhodiumdraht für Laboratoriumsöfen.) Ilja Westermann. *Metallwirtschaft*, Vol. 11, Mar. 11, 1932, pages 152-153.

Furnaces with Pt wire as a heating medium cannot be used above 1550° C. Ir is too brittle to be used in wire form. With Ir tubes 1700° C. can be reached, but in the presence of O the expensive Ir is quickly used up. For oxidizing atmosphere Rh wire forms a very good heating medium and can be used with safety up to 1700° C. The Rh wire is very carefully wound on a round piece of wood covered with paraffin. A piece of Pt wire is welded to each end to form the electrical connections. After building up the insulating material around the winding, inside of a fireclay tube, the whole mass is heated to dry the insulating material. The paraffin melts and the piece of wood is drawn out. CEM (21)

New Radiation Elements with Increased Sensitivity and Stability. [Neue Strahlungsmessgeräte (Thermoelemente) von gesteigerter Empfindlichkeit und Einstellgeschwindigkeit.] C. Müller. (Phys. Techn. Reichsanstalt) *Die Naturwissenschaften*, Vol. 19, May 15, 1931, pages 416-419.

Radiation thermo-elements are described of maximum 2/10,000 mm. fineness. The new method of preparing these highly sensitive thermo-couples replaces the widely used soldering and welding and prepares a thermo-electrically active alloy by a diffusion process. For instance, a Ni wire is coated with 2 metals, e.g. Cr and Cu, over different parts of its length by electrodeposition. Annealing results in a diffusion thus yielding a Constantan and Cr-Ni alloy of great thermal power. The former thermo-couples of Moll, distinguished by their low heat capacity and short times of coming to rest are considerably surpassed as shown by several experiments. The new thermo-couples are marketed by the Schwarzlose Laboratorium, Berlin. EF (21)

Utilization of Rhodium Implements for the Investigation of Oxide Systems. (Die Verwendung von Rhodiumgeräten zur Untersuchung von Oxydsystemen.) G. Trömel & F. Weber. *Die Naturwissenschaften*, Vol. 19, June 5, 1931, pages 519-520.

The utilization of the usual crucible material for melting oxides is critically discussed. The use of Pt and Ir is prohibitive above 1600° C. and in vacuo respectively. For an investigation of the ternary $CaO - P_2O_5 - SiO_2$ system, Rh crucibles of W. C. Heraeus-Hanau were successfully employed in a high frequency furnace. The temperature measurement was performed by an Ir/Rh — Ir/Ru thermo-couple. In another furnace, the Pt-resistance winding was replaced by Rh and the Marquardt Mass was replaced by Zr-oxide. EF (21)

A New Apparatus for Determination of Melting Points. Mototaro Matsui & Hirondo Kato. *Journal Society of Chemical Industry*, Japan, Vol. 35, Apr. 1932, pages 169B-171B.

Describes and illustrates the new apparatus for determining the melting points of metals, and the method for using it, as well as its advantages and superiority to that of the Denis instrument. MAB (21)

Workshop Spectroscope for Steel Examination. *Engineering*, Vol. 132, Dec. 11, 1932, pages 746-748.

Illustrates and describes Spekker Steeloscope made by Adam Hilger, Ltd., London. The instrument consists of a tripod on which is mounted a box containing the prisms. Two tubes are attached to this box, one carrying the slit and the other the eyepiece. On the eyepiece end are engraved a number of lines, each marked with the chemical symbol of one of the alloying elements. An arrow is engraved on the sliding plate carrying the eyepiece and by moving the latter so that the arrow coincides with one of the fixed marks, the part of the spectrum containing the most distinctive lines of the element to which the mark relates will be brought into the field. The elements provided for include: Cr, V, Sn, Mn, Co, Ti, Ni, Cd, Cu, W and Mo. The instrument can be secured in a modified form for examining non-ferrous metals and alloys. LFM (21)

Testing Machines. H. O. Hem. *Scale Journal*, Vol. 18, Apr. 1932, pages 6-8.

A few universal testing machines for physical properties are described quite generally. Ha (21)

FOUNDRY PRACTICE & APPLIANCES (22)

Remarks on the Paper "Practical Silver Art Casting." (Zu dem Artikel "Praktischer Silberkunstguss.") F. Göcking. *Deutsche Goldschmiedezeitung,* Vol. 35, July 30, 1932, pages 311-312.

The author rejects some of the statements made in a paper in *Deutsche Goldschmiedezeitung,* Vol. 35, July 2, 1932, pages 276-277. GN (22)

Bronze in the Foundry. Wesley Lambert. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 85-87.

Good practice for melting bronze is described together with the preparation of the molds. A table lists the composition of many bronzes and the uses to which they are put. PRK (22)

Controversies Between Machine Designer and Foundry. (Reibungsflächen zwischen Maschinenbau und Giesserei.) C. Müller. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 12, 1932, pages 233-235.

The paper discusses the points which frequently cause controversies between foundry and designer: proper dimensions, porosity, ununiform hardness of the castings, defects of minor importance. GN (22)

Mold Handling Methods in Foundries. Wm. L. Hartley. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Materials Handling, pages 59-63.

The mold-handling problem and present day practice in application of mold-handling devices in intermittent and semi-continuous foundries is discussed. A few installations are described. Ha (22)

Making the Mold of a Spiral 4000 mm. in Length and 300 mm. in Diameter. (Die Herstellung der form zu einer Schnecke von 4000 mm. Länge und 300 mm. Durchmesser.) Arno. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 15, 1932, pages 208-210.

Detailed description of the molding practice. GN (22)

Contraction Allowance Varies with Conditions. R. A. Bull. *Foundry,* Vol. 59, Dec. 1931, pages 35-36.

Slightly abridged from *Research Group News.* Factor of shrinkage incident to change of steel from molten condition at high temperature to solid form at atmospheric temperature is important in respect to strains set up in steel at various stages. Contraction figures vary not only because pouring temperatures vary, but contraction allowances must be regulated in accordance with design. VSP (22)

The Layout of the Foundry. (Die Anlage der Giesserei.) G. Krebs. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 29, 1932, pages 220-221; June 12, 1932, pages 235-236.

Discussion of the points to be borne in mind in the layout of foundries. GN (22)

Testing and Rating of Core-Sands and Core-Binders. (Ueber die Prüfung und Bewertung von Kernsanden und Kernbindemitteln.) Th. Klingenstein. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns,* Vol. 1, Dec. 1931, pages 175-185.

The possibilities of commercial core-binders and their rating and prices are discussed and testing methods and numerical values of properties of sand, oils and finished cores given. A bending number is derived which makes possible a rating of the binder. 30 references. Ha (22)

The Bessemerization of Bell Bronze. John B. Kasey. *Metal Industry,* N. Y., Vol. 30, May 1932, pages 185-186.

Results are given in tabular form of experiments carried out in Moscow, U. S. S. R., in a study of the recovery of Sn from bell bronze. PRK (22)

Arrangement of Pattern and Mold for a Part of a Large Gas Engine. (Modell- und Formaufbau für ein Grossgasmaschinen-Mittelstück.) H. Erkart. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 29, 1932, pages 228-231.

A detailed description is given of pattern design, pattern making and molding practice of the complicated part of a large gas engine. GN (22)

Melting and Casting of Aluminum Alloys. (Zum Schmelzen und Giessen von Aluminiumlegierungen.) W. Fröhlich. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 15, 1932, pages 206-207; May 29, 1932, pages 224-225.

The paper gives no general description of the common melting and casting practice of Al alloys but considers the most important and most frequent mistakes made in processing such alloys. The first installment deals with the application of preliminary alloys in melting Al-alloys and the application of fluxes and purifiers. A simple effective purifier is a mixture of 85% NaCl and 15% CaF_2 or cryolite. A better purifier is the following mixture: 2 parts of cryolite, 2 parts of K_2CO_3, 1 part of borax, 10 parts of Na_2CO_3. About 1.5 kg. of this mixture used per 100 kg. of the melt. The 2nd installment gives practical hints as to the casting practice. To accelerate the melting process and for a better protection against oxidation the ladle should be completely emptied in casting. Failures due to improper casting temperatures and improper treatment of the crucibles are particularly dealt with. The paper concludes with considerations on molding practice and failures due to improper molding. GN (22)

Plasticity Investigations with synthetic Molding Sand Mixtures compared with the Results obtained with Natural Sands. (Bildsamkeitsuntersuchungen an synthetischen Formsandgemischen im Vergleich mit den an natürlichen Sanden erzielten Ergebnissen.) H. Nipper & E. Piwowarsky. *Mitteilungen aus dem Geisserei Institut der Technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 7 pages.

The methods for testing the plasticity of a molding sand are reviewed and the roll test was selected for the tests made here to determine the plasticity and its connection with shape of grain, size of grain, content of clay and humidity. The results are given in tables to which the reader must refer. Ha (22)

Base Plate of a Turbo- Compressor made with Templet. (Mittels Ziehschablone hergestellte Grundplatte für Turbokompressor.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 10, 1932, pages 277-278.

Discussion of procedure to be followed. GN (22)

New Machine for Instantaneous Molding of Cores by Blowing. (Nouvelle Machine a Mouler Instantanement les Noyaux par Soufflage.) E. Monnot. *Revue de Fonderie Moderne,* Vol. 26, May 25, 1932, pages 167-169.

A machine is described which forms small cores in quantity production by blowing the sand into the core-box under air pressure. Ha (22)

Molding and Pouring of a Locomotive Smoke Stack (Formen und Giessen eines Lokomotivschornsteins). *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 26, 1932, pages 270-271.

Illustrated description of molding and pouring practice. The coöperation between pattern-shop and foundry is emphasized. GN (22)

Making a Large Turbine Cylinder Casing Pattern. J. R. Moorehouse. *Foundry Trade Journal,* Vol. 46, May 5, 1932, pages 277-278.

Article shows the methods adopted in building up the shape of a 50,000-kw. (and over) turbine cylinder casing pattern, having a metal thickness of approximately only 1¼". OWE (22)

Contraction, Distortion and Camber in Grey Iron Castings. E. Longden. *Foundry Trade Journal,* Vol. 46, June 30, 1932, pages 395-398, 408; Vol. 47, July 7, 1932, pages 3-5, 12.

The author points out that there is a striking lack of data and of standards for camber allowances in castings. A chart showing the relationship between camber and the various dimensions of large machine-tool castings is shown. Such charts cannot be applied generally, since heavy castings do not contract in conformity with the ordinary standard allowances, the same amount of metal poured into a simple plate, a gear box, or a plain block casting disclosing altogether different behavior in the 3 castings. The importance of design in its bearing on the camber of castings is dealt with in brief and attention is directed to the influence upon camber of such factors as mold materials, metal temperature, methods of molding, etc. OWE (22)

Oil-Cores in the Manufacture of Steel Castings. (Oelkerne bei der Herstellung von Stahlguss.) H. Nipper & K. Krekeler. *Die Giesserei,* Vol. 19, June 24, 1932, pages 247-249.

On account of the high temperatures used in casting alloyed steels the employment of properly burnt oil-cores is important in order to obtain satisfactory castings. The method of making these cores is described in detail. Ha (22)

Some Considerations in Gating and Pouring Castings. (Eenige geschouwingen over het maken van gietloopen en het gieten van gietstukken.) E. V. Ronceray. *De Gieterij,* Vol. 6, June-July 1932, pages 62-65.

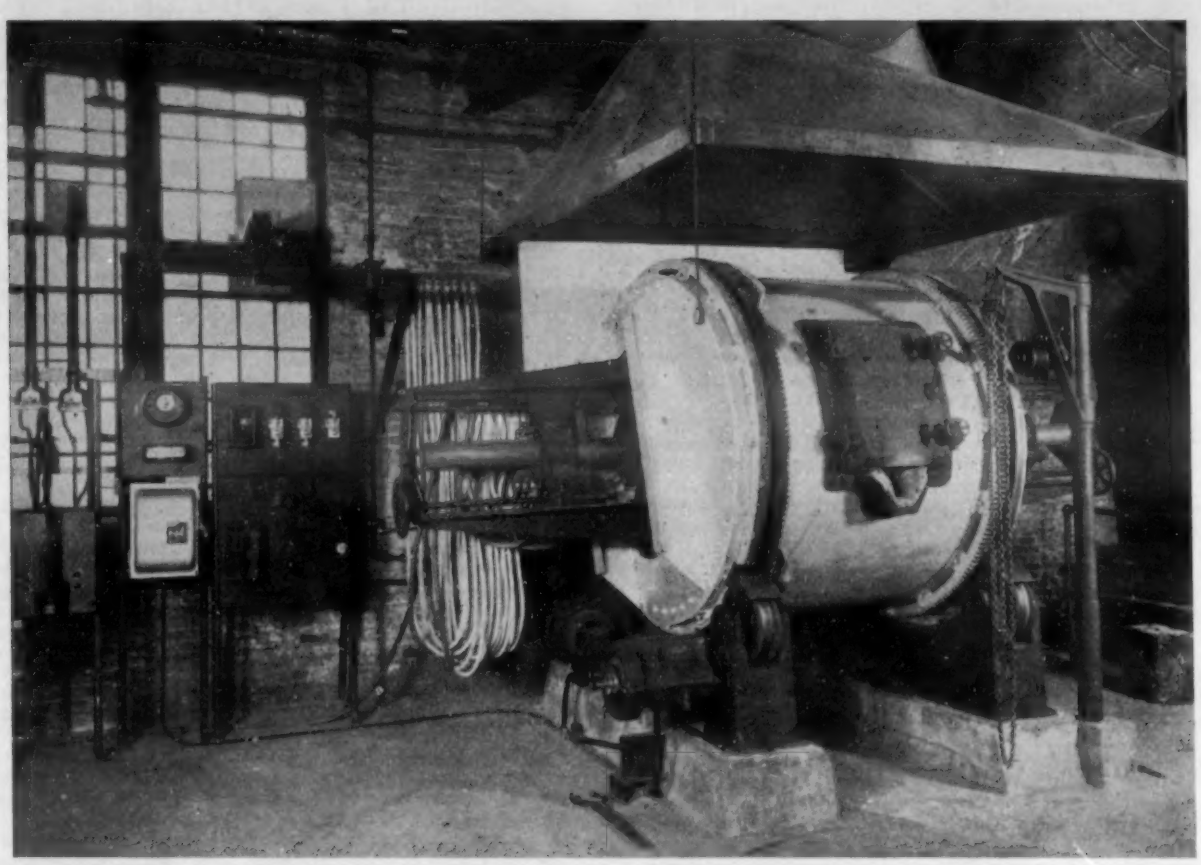
Paper read before American Foundrymen's Association. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. MPW (22)

A Contribution to the Knowledge of the Heat Resistance of Molding Sands. (Beitrag zur Kenntnis der Feuerbeständigkeit von Formsanden.) H. Nipper & E. Piwowarsky. *Mitteilungen aus dem Giesserei-Institut der Technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 6 pages.

3 kinds of heat resistivity are distinguished: (1) simple heat resistance or the strength on heating, (2) heat resistance at a simultaneous mechanical and temperature stresses, and (3) heat resistance at simultaneous mechanical, temperature and chemical stresses. Methods for the determination of the behavior of a sand according to these 3 kinds of stress are described; the tests made permitted some conclusions with regard to the lowering of the melting or sintering point with increasingly fine grain and decreasing velocity of heating. The behavior of sand cones in Fe of different temperature is recommended as very useful in judging the quality of a sand. Ha (22)

The Testing of Molding Sand with Respect to Its Structural Elements. (Ueber die Prüfung des Formsandes auf seine Strukturelemente.) H. Nipper & E. Piwowarsky. *Mitteilungen aus dem Giesserei-Institut der Technischen Hochschule Aachen,* Vol. 2, Oct. 1931, 6 pages.

The differences between molding sands can consist in the mineralogical composition of the grain, size of grain, shape and surface of the grain, contents of clay and its composition, by the distribution of the constituents and humidity. Testing methods are reviewed and tests made, the results of which are used to determine beforehand the properties of a molding sand from its structural elements. Ha (22)



Chilled Cast Iron and the Avoiding of Sharp Transitions in Gray Cast Iron. (Der Hartguss und die Ueberbrückung schroffer Uebergänge beim Grauguss.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 7, 1932, pages 303-306.

The paper discusses the importance of proper dimensions of the Fe molds, choice of suitable casting temperatures and composition of the charge. As the average composition of good chill Fe the following is given: 3.5% C, 1% Si, .5% Mn with the lowest possible content of S and P. The molds for such Fe should be made of Fe with low contents of C, Si, Mn, P and S. If possible the molds should be annealed before use, to make them more resistant to the attack of the hot Fe. Facing of the molds with graphite is discussed. Examples for proper wall thicknesses of molds are given. Points to be borne in mind in using permanent molds are discussed. The use of chill molds is dealt with. GN (22)

Directions for the Preparation of Molding Sand and the Choice of Binders for Cores. (Richtlinien für Formsandaufbereitung und Wahl der Bindenmittel für Kerne.) Walter Obst. *Die Giesserei,* Vol. 19, June 24, 1932, pages 249-250.

The properties of sand and materials for cores are reviewed and the requirements for good castings discussed. The sand should be tested for content of fine sands; addition of quartz increases refractoriness. Molasses and resins with sulphite lyes are used as binders. Oil-cores are made of a mixture of 5 kg. linseed oil to 100 kg. sand, and in order to increase the porosity, rye flour and resin is added. Quite recently, caoutchouc is used as core binder which gives the core a higher strength even if it is not quite dry. The caoutchouc is dissolved in petroleum or naphtha; a 7% solution is usually employed, about 8 l. for 450 g. The heat of the casting destroys the core; the latter therefore last as long as required. Ha (22)

PRECISE CONTROL

THE DETROIT ROCKING ELECTRIC MELTING FURNACE FOR GRAY IRON, MALLEABLE, ALLOY STEEL . . . AND ALL NON-FERROUS METALS

offers unequalled facilities for the economical production of various types of castings with precision in chemical and physical characteristics. The accuracy of temperature control and complete homogeneity which are insured by the rocking action of the DETROIT Electric Furnace, together with its simplicity of operation, are determining factors in the highly satisfactory results being obtained by over sixty users in the ferrous field and over five hundred users in non-ferrous melting.

Summary of experimental work as brought out in *Iron Age* 128 (1931) pages 1434-1436, 1492-1493, 1624-1625 & 1630 and presented at semi-annual meeting of Steel Mill Committee. Detroit, November 24-25, 1931. 13 references. DTR (23)

Modern Furnaces for Annealing Cast Steel. (Moderne Ofen zum Glühen von Stahlguss.) H. KALPERS. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Mar. 6, 1932, pages 94-98; Mar. 20, 1932, pages 113-115.
Furnaces for annealing cast steel are described. GN (23)

The Design of Normalizing Furnaces. E. E. GRIFFITHS. *Rolling Mill Journal,* Vol. 5, May 1931, pages 369-370, 379.
Paper presented before the British Institution of Mechanical Engineers. See "Factors Influencing the Design of Normalising Furnaces," *Metals & Alloys,* Vol. 2, Mar. 1931, page 75. JN (23)

Highest Temperatures in the Design of Resistance Furnaces. (Höchsttemperaturen im Widerstandsofenbau.) F. LAUSTER. *Elektrowärme,* Vol. 2, May 1, 1932, pages 103-106.
For temperatures above 1100° C. for which Cr-Ni resistances can not be used, Mo can be used with advantage, in spite of its high temperature coefficient. Arrangements must be made to protect the glowing resistance elements against oxidation; usually a gas-tight enclosure is provided, which sometimes is filled with a protective, such as a N-H mixture; the consumption is about 30 l./hr. Several constructions are described; one furnace for 1400° C. uses 26 kw. Because of the comparatively high temperature coefficient specia' care must be taken in starting the furnace in order not to overload the resistances. Ha (23)

Electric Continuous Furnaces for the Annealing of Metal Strips. (Elektrodurchziehofen zum Glühen von Metallbändern.) O. JUNKER. *Elektrowärme,* Vol. 2, Jan. 1932, pages 10-15.

Experimental Investigations of a Theisen Cleaner for the Secondary Cleaning of Blast Furnace Gases. (Recherches experimentales sur un Desintegrateur Theisen pour l'Epuration secondaire des Gaz de Hauts Fourneaux.) M. STEFFES. *Revue Technique Luxembourgeoise,* Vol. 24, Jan.-Feb. 1932, pages 12-17.
Tests of a Theisen cleaner were run without gas, without water and with gas and water. The results are given in detail in diagrams and tables and the most economic conditions of operation with regard to output, pressure and degree of cleaning determined. Ha (23)

The Use of Pulverised Fuel and Pulverisers in the Foundry. P. HOWDEN. *Foundry Trade Journal,* Vol. 46, Mar. 10, 1932, pages 157-161.
Paper read before the Sheffield Branch of the Institute of British Foundrymen which discusses the type of coal suitable for pulverized-fuel firing, pulverizers, combustion and burning equipment. The use of powdered fuel in the melting of iron is considered, especially the Brackelsberg, Sklenar and Sesci furnaces. The advantages of using pulverized fuel are described. OWE (23)

Foundry Installs Large Oven. *Foundry,* Vol. 59, May 15, 1931, pages 95-96.
A core-oven, approximately 235 ft. long, of the roller conveyor type, claimed to be the largest in the world is described. The operating temperature is about 500° F. It was designed and built by the Foundry Equipment Co., Cleveland, for the General Steel Casting Corporation. VSP (23)

Small Continuous Conveyor Ovens Pay in the Smaller Plant. *Iron Age,* Vol. 128, Nov. 5, 1931, pages 1166-1169.
A continuous unit has certain well defined economic advantages over the intermittent oven. 3 installations of continuous small sized ovens are described one an "A" type oven, one a vertical and the third, an inclined oven. VSP (23)

The Improvement of Upper-Silesian Blast Furnace Coke and the Oxidation of Upper-Silesian Coals. (Ueber die Verbesserung von oberschlesischen Hochofenkoks und die Oxydation von oberschlesischen Kohlen.) W. KOPPERS. Doctor's thesis, Technische Hochschule Aachen, 1931. Paper, 6 x 9½ inches, 33 pages.
Upper Silesian coking coals alone give fingery, friable coke which breaks down to sizes undesirable for blast furnace use. Additions of semi-coke from non-coking Upper-Silesian coal, oxidized coking coal or semi-coke from oxidized coking coal give stronger, more blocky and improved coke. Fine grinding gives better quality coke having smaller cells and stronger cell walls. Narrow ovens and high temperatures are necessary for good coke. Microscopic studies of the cokes show no graphitization, but unusual amounts of precipitated graphite or retort C are found in the cell spaces and coke fissures. The importance of rate of heating during coking, of damage due to slow heating of high volatile coking coal and of long standing of finished coke is indicated. The addition of the above-mentioned inert materials reduces heat requirements and gives shorter coking time. Fresh and oxidized coking coals, non-coking coals and semi-cokes were extracted by benzine with pressure and the bitumins studied. Results are tabulated. Micro and macrophotographs of coke sections are given. FBH (23)

Coke in Electrometallurgy (Le coke en electrometallurgie). *Journal du Four Electrique,* Vol. 41, Feb. 1932, pages 60-62.
Electrochemical industries using a coke are giving to the chemical composition and physical properties of coke the same attention as to those of other raw materials. JDG (23)

Town Gas Fired Strip Annealing Furnace. *Iron & Coal Trades Review,* Vol. 124, Feb. 26, 1932, pages 356-357.
The construction of the furnace and its regulation of temperature is described; the consumption of 500 B.t.u. gas for heating is 1.3 ft.³/lb. of gross charge. The efficiency of the furnace is 33.8%. Ha (23)

Repairs to Steel Furnaces. WALTER LISTER. *Metallurgia,* Vol. 6, June 1932, pages 61-62, 65.
Gives detailed directions for repairing regenerators, overhauling the furnace and replacing the regenerators. JLG (23)

1 **Surplus Heat Recovery from the Open-Hearth.** W. GREGSON. *Iron & Coal Trades Review,* Vol. 124, June 10, 1932, pages 954-956.
From any open-hearth furnace operating on fuel gas, or a combination of gases giving a similar mean analysis of fuel, waste-heat can be recovered by steam raising in properly designed boiler plants with a very definite lowering of the cost of production of the prime product. A few typical constructions of waste-heat boilers and installations are described and tables and curves given showing combustion analyses and heat content of gases and combustion products. Ha (23)

2 **Leakage, Insulation and Setting up of Open Hearth Regenerators. (Ueber Undichtheiten, Wärmeschutz und Beaufschlagung von Siemens-Martin-Kammern.)** FRANZ KOFLER. *Archiv für das Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 493-502.
Report 224 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion. Practical tests were carried out on experimental chambers in Ruhrort-Meiderich Plants. Leakage in brickwork was given by a permeability number, and curves illustrating this number were drawn for 5 types of brickwork construction. An example giving gas leakage before and after tightening up brickwork shows a gas saving of 4% or 0.20 R.M./ton steel. The effect of leakage air on temperature and of O_2-content on temperature decrease of gases in the air chamber of an open-hearth furnace is shown graphically. In setting up an open-hearth regenerator it is necessary for obtaining uniform heat exchange that the velocity of the gases during heating and cooling periods be as high and uniform as possible in a cross section normal to direction of gas flow. DTR (23)

3 **The Valve System of Regenerative Furnaces and a New Valve Construction. (Synpunkter pa regenerativt eldade ugnars vetilsystem samt en ny ventilkonstruktion.)** SIXTEN WOHLFAHRT. *Jernkontorets Annaler,* Vol. 116, Mar. 1932, pages 107-119.
A new valve is described, which, for 4 regenerators consists of 4 slide valves and 4 disc vaives, 1 valve of each kind being operated with 1 and the same wire. The slide valve being heavier than the disc valve, the former cannot open until the latter is closed. With the disc valve closed, the slide valve may be fixed in any desired position. The valve system has been tried in practice with the result that the production was increased from 12,000 to 14,000 tons, while the fuel consumption was decreased 14%. HCD (23)

4 **Soaking Pits without Checkers.** J. B. NEALEY. *Blast Furnace & Steel Plant,* Vol. 20, May 1932, pages 428-429.
Except for the omission of the plan view, this is the same as the article in *Blast Furnace & Steel Plant,* Vol. 18, Nov. 1930, pages 1707-1708. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 24. MS (23)

5 **Crucible Furnaces.** G. L. CASSIDY. *Foundry Trade Journal,* Vol. 46, May 26, 1932, pages 319-323.
The author describes and discusses the history of the crucible furnace, the characteristics of plumbago, the coke-pit type of furnace, the types of coke generally available for use in these furnaces in Great Britain, the cost of crucibles, abuses to which crucibles are subjected in coke-pit furnace practice, various types of tilting furnaces (including oil-fired equipment, gas furnaces and electric furnaces), furnace atmospheres, the attack of fluxes, metal losses and labor costs (British practice). OWE (23)

6 **Gas-Furnace Attains Temperature Exceeding Melting Point of Platinum.** *Engineering & Mining Journal,* Vol. 133, Aug. 1932, pages 449-450.
A temperature of 1850° C. has been attained in the Degussa Lilliput furnace, a gas-heated laboratory furnace manufactured by Deutsche Gold u. Silber-Scheideanstalt, Frankfurt-on-the-Main, Germany. The maximum temperature was recorded in 15-20 minutes. The operation is on the principle of surface combustion, in contact tubes possessing a highly reactive surface. Low resistance to flow of gas and air, symmetrical distribution of flame, and highly effective insulation insure most favorable thermal conditions. High-grade corundum and MgO are used in furnace construction. 5 sizes are made with extreme melting volumes of 15-1000 in.³. A temperature of 2000° C. may be obtained in 1½-5 hrs. according to the size. WHB (23)

7 **The Practice of the Pulverized Coal Rotating Melting Furnace. (Aus der Praxis des Kohlenstaub-Drehtrommelofens.)** H. KALPERS. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 24, 1932, pages 289-290.
Experiences with the new French Sesci furnace which is similar to the German Brackelsberg furnace are discussed. A short combustion chamber is arranged between the burner and the melting space. Rocking of the furnace is superior to continuous rotating. Metal waste through oxidation is less than 1%. Fuel consumption is 17.2% of the charge, power consumption is 7.5 kwh./ton, including coal grinding it is 12 kwh./ton Fe. The furnace lining stands 150 melts of machine casting, 130 melts of pearlitic Fe, 110-120 melts of malleable Fe. Composition of charges of various Fe is given. GN (23)

8 **The Brackelsberg Furnace in the Enameling Plant. (Der Trommelofen im Emaillierwerk.)** P. EYER. *Emailletechnische Monatsblätter,* Vol. 8, Apr. 1932, page 30.
In making enamel cast Fe in the Brackelsberg furnace a relatively high amount of steel scrap can be used. Fe made in the Brackelsberg furnace is ideal for enameling purposes. Few failures in enameling are due to the Fe. GN (23)

9 **The Electric Enameling Furnace. (Der elektrische Emaille Brennofen.)** M. BECKER. *Emailletechnische Monatsblätter,* Vol. 8, Aug. 1932, pages 59-60.
The paper discusses the advantages of electric enameling furnaces. GN (23)

10 **Vacuum Casting.** H. T. REEVE. *Metals & Alloys,* Vol. 2, Oct. 1931, pages 184-185.
An induction furnace set-up for melting and casting metals and alloys in vacuum is described. It has been used successfully to produce ingots of Pt up to 600 g. WLC (23)

REFRACTORIES & FURNACE MATERIALS (24)

Blast Furnace Linings. W. J. Rees. *Iron & Coal Trades Review,* Vol. 124, May 27, 1932, page 882.

The Department of Refractory Materials of Sheffield University carried on investigations on the durability of blast furnace linings which led to the following suggestions for the reduction of the corrosion of the lining: Resistance to slag attack is promoted by the use of well burned bricks of good shape, low permeability and good volume stability at high temperatures, made from aluminous clays with a refractoriness not below cone 30. The cement used should be finely ground but contain a high proportion of grog to avoid contraction on firing. Close jointing of the bricks is especially important. Resistant to C deposition is promoted by the use of bricks of low permeability, well burned and free from ferruginous segregations. An iron oxide content not higher than 2.5% seems desirable. Resistance to mechanical wear is promoted by use of bricks with a high cold-crushing strength, close texture and incipient vitrification appear to assist the retention of resistance to mechanical shock and abrasion at the temperatures of the upper parts of the blast furnace. Ha (24)

Refractory Materials. Alexander H. Hays. *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 292, 294; Apr. 1932, pages 368, 370; May 1932, pages 453-454.

From *World Power.* General discussion of fire-clays, silica, volume changes and transitions of silica at various temperatures; high-alumina refractories such as bauxite, diaspore, sillimanite, mullite and corundum; chromite refractories, dolomite; magnesite; silicon carbide; zirconia and properties of refractories. MS (24)

Development of Refractories in 1931. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 59-60, 63.

Improvement in uniformity of clay and silica brick with regard to burn and size has lengthened life of furnace linings. A 9" straight 3" in thickness instead of 2½" has been introduced enabling 20% more wall area to be laid per mason hour. Chrome brick of coarser grain size, with an improved bond and heat treated in tunnel kilns give considerably longer furnace service. Being cheaper, they are supplanting magnesite brick in open-hearth and heating furnaces. Attempts are being made to develop a new type of magnesite brick. Encouraging results have been obtained in Europe with an electrically sintered magnesite brick having a softening point above 3000° F., and a melting point close to 5000° F. Good high alumina, mullite and sillimanite brick are beginning to find the places in furnaces where they may be substituted economically for the lower priced clay brick. Plastic refractories are coming into steel mill use because of lower prices and improved quality. Mills are salvaging brick bats from dismantled furnaces. Manufacturers and consumers are coöperating in making and interpreting tests. MS (24)

Open Hearth Furnace Regenerator Brick. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 116, 118.

Primary factor in manufacturing a regenerator brick is to have the lowest possible porosity. Dry-press method has done much to lower the porosity and to increase uniformity. Hard brick low in porosity accumulate less slag and cinder. It is generally understood that silica brick in regenerators are necessitated by improper design of furnace ports. Silica brick are unsuitable for the top courses because of their porosity. However, brick high in refractoriness, such as the high-alumina class, are suitable for this purpose so far as serving in high temperatures is concerned. More thought should be given to the placement of the bridge wall. Additional slag-pocket space can be provided by setting the bridge wall back into the chamber proper. This would prevent heavy particles of slags being carried into the regenerator flues. MS (24)

Some of the Newer Uses for Silicon Carbide. Charles McMullen. *Transactions Electrochemical Society,* Vol. 59, 1931, pages 81-86.

See *Metals & Alloys,* Vol. 2, Aug. 1931, page 152. (24)

Sinter Corundum. (Sinterkorund als Werkstoff.) *Werkzeugmaschine,* Vol. 36, June 15, 1932, pages 205-206.

The paper discusses the production, properties and application of sinter corundum, made according to a special process by the Siemens Company. The excellent properties result from the following comparison:

	Mica	Porcelain	Steatite	Sillimanite	Sinter Corundum
Heat conductivity kg. cal/m. hr. °C.	.3	.84	1.25	1.45	16.8
Melting point °C.	1380	1670	1560	1816	2050
Insulating capacity up to °C.	600 (decomposes)	450 (softening of the vitreous component)	550	650	800 (crystalline)
Impact strength in cm. kg. at 600 °C.	...	45	50	120	180

GN (24)

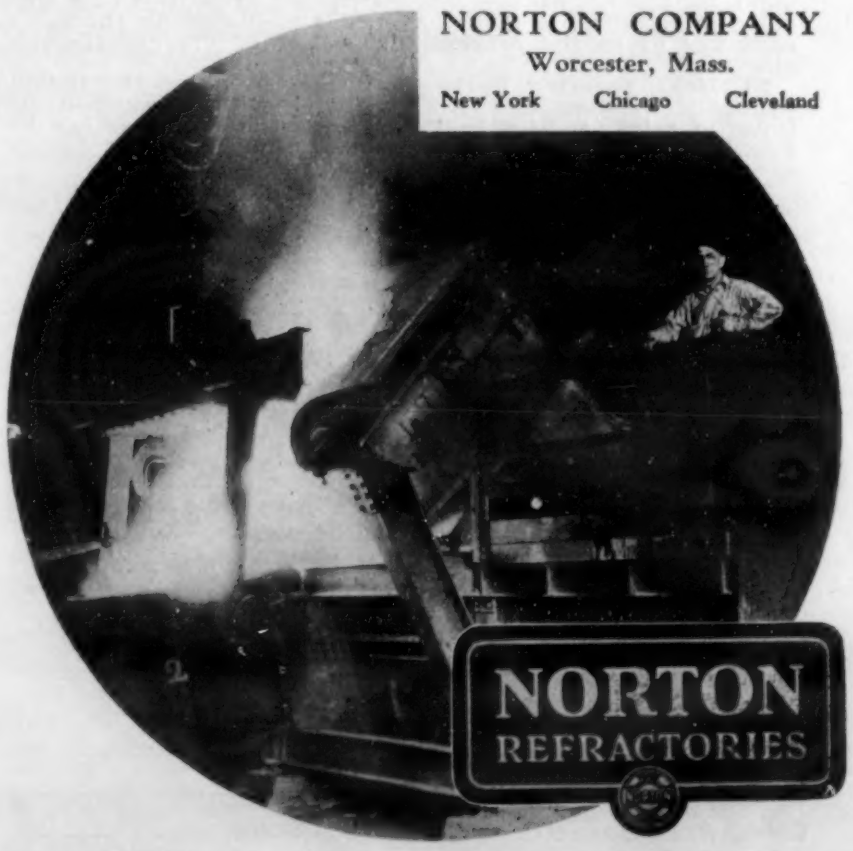
Sinterkorund—A New Ceramic Material. *Industrial Chemist,* Vol. 8, Apr. 1932, pages 150-152.

5 references. Sinterkorund is essentially pure crystalline alumina containing 99.3 to 99.8% Al_2O_3. The method of preparing is described briefly. Chemical and physical properties are given. Tables of data such as thermal conductivity, thermal expansion, electrical resistance etc. are given. Many applications are cited. RAW (24)

An Apparatus for Testing Heat-Insulating Bricks. T. H. Blakely & J. W. Cobb. *Journal Society Chemical Industry,* Vol. 51, Mar. 11, 1932, pages 83-89T; *Blast Furnace & Steel Plant,* Vol. 20, May 1932, page 452.

The apparatus is used to measure the heat conductivity of firebrick, either one or two bricks being used, the difference in temperature of the air and of a dull black surface radiating and convecting freely to its surroundings being used as a measure of the heat flowing through the test brick. Considerable data on different kinds of heat insulating bricks are given. MS+VVK (24)

For Small Laboratory Furnaces or the Largest Commercial Furnaces—



High Temperature Refractory Cements

NORTON High Temperature Cements are so varied in their composition that practically any severe condition — chemical, electrical or physical—can be met with one or more of them. Whether you are building a new installation or are repairing an old one you will do well to investigate these well-known and widely used mixtures.

They are made of silicon carbide (Crystolon), fused alumina (Alundum) and electrically fused magnesia and utilize to the fullest extent the properties of these super-refractory materials.

New York Chicago Cleveland

MANUFACTURERS' LITERATURE REVIEWS

16 **Motors**—The Lincoln Electric Co., Cleveland, Ohio, has distributed a folder describing the construction of their "extra horsepower" motors.

17 **Alloys**—A folder of interest to foundrymen has been issued by H. Kramer & Co., 21st & Loomis St., Chicago, Ill. It describes the use of their Special, Intermediate and Fluxing alloys in producing improved castings.

18 **Stainless Steels and their Uses**—300 uses for stainless steels are discussed in detail in a 20-page booklet issued by Electro Metallurgical Co., 30 East 42nd St., New York, N. Y.

19 **Arc Welding Equipment**—Bulletin No. E-9 of the Hobart Bros. Co., Troy, Ohio, tells how factories may reduce material, labor, overhead and selling costs with welded steel and describes their welding equipment.

20 **X-Ray and the Foundry**—A pamphlet prepared by the Kelley-Koett Mfg. Co., Covington, Ky., discusses the application of X-ray inspection to castings, and welds. It is fully illustrated.

21 **Supertemp**—This steel was developed by Bethlehem Steel Company for use in parts that must retain their strength and be free from creep at high temperatures. A leaflet describing it including a chart showing its physical properties may be obtained from the company.

22 **Turbo-Compressors**—A bulletin describing the application of turbo-compressors to foundry cupolas has been issued by the Spencer Turbine Co., 521 New Park Ave., Hartford, Conn. They give the operator a dependable air supply under absolute control both as to volume and pressure.

23 **Furnaces**—A folder descriptive of their gas carburizing machines and gas heating machines for continuous heat treating may be obtained from the American Gas Furnace Co., Elizabeth, N. J.

24 **MacHempite**—A recent bulletin of the Mackintosh-Hemphill Co., Pittsburgh, Pa., describes their "MacHempite" heat treated alloy steel castings both as to physical properties and applications.

25 **Arc-Welded Rolled Steel**—A leaflet recently sent out by Lukenweld, Inc., Coatesville, Pa., stresses the use of Lukenweld construction in building bases and other units of machinery and equipment.

26 **Electric Fusion Weld**—In a folder issued by the Struthers-Wells Co., Warren, Pa., illustrations are shown of a welded vessel tested to 5000 pounds pressure with no sign of failure in the weld or steel plate.

27 **Blast Gates**—Bulletin No. 325 of the W. S. Rockwell Co., New York, N. Y., is devoted to their air-tight blast gates, illustrating their different styles of control and giving their dimensions. Bulletin No. 332 of the same company discusses their electric convector furnaces for drawing and bluing.

28 **Nickel Cast Iron News**—The October issue of this publication of the International Nickel Co., New York, N. Y., features an article entitled "Recommended Methods of Adding Alloys to Cast Iron." This issue also includes number fourteen of their "Intimate Chats on Metallography."

29 **Refractories**—Laclede Mullite, a non-spalling, slag resisting, non-shrinking, highly refractory brick is described in a leaflet distributed by the Laclede-Christy Co., St. Louis, Mo.

30 **Rust Prevention**—Bulletin No. 20 of the American Chemical Paint Co., Ambler, Pa., discusses the causes and prevention of rust. A.C.P. elastic primer for coating ship bottoms and decks is described.

31 **Die Castings**—An attractive booklet prepared by the New Jersey Zinc Co., New York, N. Y., includes charts and tables on the effect of aging treatments on tensile strength, impact strength and dimensions of Zamak alloys. Heat treatment for stabilizing the dimensions and properties of a zinc die casting alloy is given. A card distributed by the same company gives the original properties of die cast Zamak alloys.

32 **Heat Treating Baths**—A 25-page booklet distributed by the E. F. Houghton Co., Philadelphia, Pa., describes the types of salts used for heat treating operations that can be done in liquid baths and contains information on the design and operation of salt bath furnaces.

33 **Galvanized sheets**—A booklet prepared by the American Zinc Institute, New York, N. Y., discusses heavy-coated galvanized sheets for roofing and siding and the weight of zinc coating needed for long life.

34 **Alloys**—An index of standard and special alloys designed for use in brass, aluminum and iron foundry practice may be procured from Alloys & Products, Inc., New York, N. Y. The list of alloys is arranged in groups, classified as to purpose and cross-indexed as to their principal constituents.

35 **Electric Immersion Units**—The Harold E. Trent Co., Philadelphia, Pa., has issued a leaflet, TB-30, devoted to electric immersion units for heating oil. Prices and sizes are given.

36 **Brine Corrosion**—A circular distributed by the Dearborn Chemical Co., Chicago, Ill., tells about their treatment for controlling brine corrosion in circulating systems and tanks. Another of their leaflets discusses their special treatment No. 134 for quick removal of scale.

37 **Lead**—The November issue of *Lead*, published by the Lead Industries Association, New York, N. Y., illustrates several interesting and unusual uses of that metal.

38 **Arc Welders**—Portable, gas engine driven arc welders are described in Bulletin 901-A of the Burke Electric Co., Erie, Pa.

39 **Welding Rods**—A leaflet sent out by the American Brass Co., Waterbury, Conn., describes their Anaconda welding rods for bronze-welding.

40 **Phoenixloy**—The Pittsburgh Rolls Corp., Pittsburgh, Pa., has developed a new hard alloy roll, Phoenixloy, for both hot and cold rolling of all kinds of flat steel, copper, brass, zinc, aluminum and nickel. A folder describing it may be obtained from the company.

41 **Sil-Fos**—Bulletin No. 5 of Handy & Harman, 82 Fulton St., New York, is devoted to their new silver brazing alloy, Sil-Fos. This alloy melts at 1300° F., resists corrosion and works well with copper, brass, bronze, nickel, Monel metal, etc. The same company has prepared the 1932 edition of their "Review of the Silver Market," a 27-page booklet.

42 **Copper**—The January issue of the Bulletin of the Copper & Brass Association, 25 Broadway, N. Y., describes New York's largest apartment, illustrating the uses to which copper is put in its construction.

43 **Optical Instruments for examining and analyzing Metals**—This catalog prepared by the Bausch & Lomb Optical Co., Rochester, N. Y., is a most attractive and useful 125-page book. In addition to illustrating and describing all types of metallographic equipment, it contains several helpful articles and shows numerous interesting photomicrographs.

44 **Electric Furnace**—A recent pamphlet issued by the Pittsburgh Lectromelt Furnace Corp., Pittsburgh, Pa., describes an installation of one of their furnaces used for manufacturing camshafts, crankshafts, brake drums, cylinders, etc.

45 **Radiography as a Tool in the Metal Industry**—The General Electric X-Ray Corporation, Chicago, Ill., is distributing reprints of this article by Fink and Archer. It is a 39-page booklet, and covers the subject as thoroughly as the space permits.

46 **Testing Soft Metals**—Bulletin H-6 of the R. Y. Ferner Co., Washington, D. C., is devoted to their Dwarf Brinell Press which is now available for testing soft metals, using a 250-kg. load instead of the 750-kg. load of the regular Dwarf Brinell Press.

GENERAL (0)

Report of the National Physical Laboratory (England) for 1930. His Majesty's Stationery Office, London, 1931. Paper, 8 x 10½ inches, 295 pages. Price 12s 6d.

Work mentioned as in progress, but not yet reported on in detail, that is of direct metallurgical interest, comprises: thermal conductivities of stainless steel at high temperatures; change of temperature coefficient of Cu-Ni wire on drawing to smaller diameter, which is being followed by X-rays; materials for gages and stability of gages of "cloudburst" hardened and nitrided steels; wear tests on jewels and pivots (in this a 0.40% C, 12½% Cr steel was found to be the harder the higher it was quenched, from 850° to 1100°C., the cone hardness from 1100° being 590 kg./mm.^{2} Hardness vs reciprocal of square of diameter of grains was a straight line); corrosion fatigue of steels and of Al and Mg alloys; creep tests at high temperatures on Mo steel and Cu steel, and effect of flue gases; scratch-hardness testing; wear testing; friction and seizing tests on oils doped with lead ethyl; Al-Cu system; Fe-Cr system, Au-Cu system; heat-treatment in controlled atmospheres; surface tension of liquid metals; Be; Ti; gases in steel; corrosion of boiler plate; tungsten magnet steel; X-ray study of carbide residues from W steels and from Si steels; X-ray study of drawn Cu wire; orientation of electro plated deposits; electron diffraction; magnetic properties of Fe Cr and Fe Mn alloys; boundary lubrication; fatigue of single crystals; adhesion of bearing metal liners to bearing backs; seizure of bronze bushings; failure of connecting-rod studs; titanium chloride treatment of Al alloys; Mg Sb, Mg Ni and Ag Hg systems; dental alloys and amalgams; and methods of chemical analysis for high Ni Cr steels. H. W. Gillett (0)-B-

National Physical Laboratory Metallurgical Researches: Annual Report for the Year 1931. *Chemical Age,* London, Vol. 26, June 4, 1932, pages 35-36.

Brief account of the work of the National Physical Laboratory, the full report of which can be obtained from H. M. Stationery Office, price 15 s. The work of the past year has consisted in the study of alternating stresses on spring steels, X-ray crystal analysis, light alloys of Al and Mg, ductile Be and lubricating oils. VVK (0)

Research and the User. *Metallurgist,* Feb. 1932, pages 18-19.

The successful application of research is in a large measure dependent upon the user's appreciation of the value of the products which it puts at his disposal. The exaggerated claims of advertisers makes it difficult to put over a really meritorious product. The endeavor of many firms to get cheapness of product at the expense of quality also hampers the development of new and better materials. VVK (0)

Technical Education and the Steel Industry. I.—Montreal Technical School. *Iron and Steel of Canada,* Vol. 15, June 1932, pages 63-66.

After dealing with the manner in which the foundations of the present technical school system in Quebec were laid, the writer discusses very completely the Montreal Technical School which was founded in 1907. Attention is given to the various courses provided by the organization. OWE (0)

Third Progress Report of the Metallurgical Advisory Board to Carnegie Institute of Technology and United States Bureau of Mines, Oct. 1928 to Oct. 1931. F. N. SPELLER & JOHN B. BEATTY. *Mining & Metallurgical Advisory Boards Coöperative Bulletin* No. 52, 1931, 21 pages.

A complete review is given on the work carried out in the study of the physical chemistry of steel making, refractories, abnormality in steel and other fundamental problems in steel making. A list of the bulletins in which the results of these investigations have been laid down is published. Ha (0)

Recent Progress in the Field of Alloys and Their Treatment. (Recents Progres dans le Domaine des Alliages et de leur Traitement.) J. COURNOT. *L'Usine,* Vol. 41, May 20, 1932, pages 25-27.

The recent developments of ultra-light metals, Mg and Be, the more scientific treatment of cast Fe, heat treatment and welding are briefly reviewed. Most of the advances made are ascribed to intensive laboratory work to maintain which is considered of greatest importance. Ha (0)

Modern Research Organizations and the American Patent System. F. B. JEWETT. *Special Reprint Publication of the Bell Telephone Laboratories,* May 1932, 9 pages.

Address presented at the opening of the new United States Patent Office, Apr. 1932. The men who wrote the patent provision into the Constitution saw not only the tremendous stimulus to an ingenious people which such a system would provide, but, beyond and above that, the enormous advantage which would accrue to the nation as a whole as a result of the exercise of that stimulated ingenuity. The existence and operation of our patent system has had a vast influence, not alone in stimulating to the limit inherent ingenuity, but likewise in greatly accelerating the application of science to the affairs of everyday life. Our urgent problems of the present and the future are not concerned with stopping or diminishing the flow of new things into the current of life's activities, but are rather the problems of finding the best way of utilizing these things and of distributing the benefits of that use to the best advantage of all our citizens. The idea that there should be a holiday in scientific research, in the quest of new and useful applications of science, or a weakening of the forces such as those which result from the urge of our patent system, as many now urge, is an abhorrent thought. The industrial research laboratory as we understand it and as it exists today in its various stages of development in different industries, is merely an organization of intelligent men, presumably of creative capacity, specially trained in a knowledge of things and methods of science, and provided with the facilities and wherewithal to study and develop the particular industry with which they are associated. The modern research organization is an industrial tool which we have evolved in the past half century for the purpose of expediting the application of science to the affairs of life. The things which the industrial research laboratory is bringing into the patent system and which are destined to alter both its internal relations and its entire relationship to the rest of the social fabric are the kind and character of its products and the method of their creation. The industrial research laboratory is not a passing phenomenon. It has become a part of the vitals of our industrial life. Its creative works will, during the next few years, do more to modify the operation and administration of our patent system than any single factor which has yet entered into it. WAT (0)

The Journal of the Institute of Metals, Metallurgical Abstracts, No. 3, 1931. Vol. XLVII. Edited by G. Shaw Scott. Institute of Metals, London, 1932. Cloth, 5½ x 8½ inches, 854 pages.

This volume collects the monthly abstract bulletins of the Institute of Metals and provides a subject and author index. The index also covers volumes 45 and 46.

The number of abstracts included are 3705 of which 522 are on properties of metals; 357 on properties of alloys; 284, corrosion, erosion and protection; 149, structure; 265, analysis; 96, laboratory apparatus; 235, physical and mechanical testing and radiology; 54, pyrometry; 295, electrometallurgy and electro-chemistry; 343, industrial uses and applications; 39, heat-treatment; 160, joining; 285, working; 74, finishing; 200, foundry practice and appliances; 138, furnaces and fuels; 80, refractories and furnace materials; and 169, miscellaneous. It includes 101 book reviews. Richard Rimbach (0)-B-

PROPERTIES OF METALS (1)

Beryllium and Its Alloys. (Le Beryllium et Ses Alliages.) *L'Usine*, Vol. 41, Apr. 15, 1932, page 29.

Methods of production and physical properties of Be are briefly described. The importance of Be as an alloying material is discussed and properties of Be- bronzes with 1.3 to 5% Be described which lend themselves particularly well as fatigue resisting materials for springs; the electric conductivity is 7 to 19 against 7 to 10 for P-bronze. Alloys of Be and Ni are very heat-resisting and hard; they maintain their mechanical resistance up to 400°C. Binary alloys of Be and Fe are of no great practical importance, while ternary and quaternary alloys show a very fine grain. A Ni steel with 1% Be and 4% Ni has a Brinell hardness of about 600. Possible further extensions of the use of Be are discussed. Ha (1)

Rhenium. (Das Rhenium.) W. Schröter. Sammlung chemischer und chemischtechnischer Vorträge. F. Enke, Stuttgart, 1932. Paper 6¼x9¼ inches, 59 pages. Price 5.50 RM.

The isolation of Re in pure compounds was announced in 1925, and a few milligrams of the metal were prepared in 1926. In 1928, a gram was prepared, and now several kilos of metal are obtained per year. Starting with Gadolinite containing five-thousandths of 1% of Re, it is separated as a sulphide, chiefly of Mo and V with some As, Pb, Pt and Ir, which contains 1½ to 2% Re. By oxidation, solution and recrystallization potassium perrhenate is obtained, the pure salt being valued at 6.50 RM/gram. Acid perrhenate solutions can be electrolysed to give finely divided Re, or large crystals of the metal can be obtained by thermal decomposition of the halide vapor phase. Finely divided Re sintered at high temperatures is ductile enough for hot-working into sheet and wire. The metal is valued at 13 RM/gram. The metal can also be made by hydrogen reduction of perrhenate at 1000°C., to a powder containing some free potassium, removable by water. This appears to be the preferred method of production. Specific gravity directly determined is about 20, by X-ray 21.4. Lattice structure is hexagonal close-packed, a = 2.752, c = 4.448, a/c = 1.616.

A drawn Re wire of 0.25 mm. diameter gave 72,000 lbs./in.^{2} tensile strength, 24% elongation. The strength is not affected by annealing in hydrogen, oxygen or oxidizing gases. The m.p. is somewhere around 3150° C. The coefficient of thermal expansion varies with crystallographic direction, from 4.7 x 10^{-6} for the a axis to 12.5 x 10^{-6} for the c axis. Electrical resistance is about that of W.

It alloys with W forming the intermetallic compound W_2Re_3 (m.p. 3000° C.) which forms eutectics at about 50 and 67 atomic % Re with W and Re with m.p. of about 2900° and 2800° C. The metal is soluble in HNO_3, slowly in H_2SO_4, insoluble in HCl or HF, attacked by fused alkalies. It is more stable in O_2, steam and CO_2 than W. It is attacked by air at 1000° C. but is stable in hydrogen. Steam attacks it at 1900° C., pre-treatment in hydrogen tends to minimize this. The occurrence of Re and the properties of its chemical compounds are discussed. H. W. Gillett (1) -B-

The Ferro-Magnetic Moments of the Elements and the Periodic System. (Les Moments Ferro-Magnétiques des Eléments et le Systeme Periodique.) Charles Sadron. *Annales de Physique*, Vol. 17, May/June 1932, pages 371-452.

Very exhaustive experiments were made to determine the variations of the absolute saturation of Ni and Co alloys as a function of the alloying material in the simple case of solid solutions. The properties of Ni-Mn and Co-Mn suggest that the Mn-atom is orientated parallel or anti-parallel to the ferro-magnetic atoms surrounding it. The Mn atom can therefore be attributed a moment of 15.0 magnetons. According to the enlarged theory from this result the atomic moments of Cr, Mo, W, Pt, Pd, Ru, V, Sb, Si, Sn, Al, Zn Cu, Au have been determined from which it follows that for elements in the same column of the periodic classification the value of the atomic moment is the same and that in the same line—that of Fe—the moment varies linearly as a function of the atomic number. The rate of variation per supplementary electron is from +5.25 magnetons of Weiss from atomic number 19 to 23 and —4.0 from 23 to 28. The experiments are described in detail and the results tabulated. Ha (1)

Magnetism of Colloidal Gold. V. I. Vaidyanathan & Balwant Singh. *Nature*, Vol. 128, Aug. 1931, pages 302-303.

Colloidal Au was prepared by reduction of $HAuCl_4$ with HCHO, coagulated and dried in the complete absence of O_2. Its magnetic susceptibility, determined in a highly sensitive Curie balance, is $\chi = 0.0804 \times 10^{-6}$, as compared with 0.15 for massive Au. It is suggested that the colloid is largely amorphous, or else that it contains a small quantity of Au in a crystalline structure different from cubical. WAT (1)

The Shift of the Transmission Band of Silver by Cold Working. Henry Margenau. *Physical Review*, Vol. 40, June 1932, pages 800-801.

It is pointed out that the shift of the reflection minimum of Ag, occurring as a consequence of cold working the Ag surface, can be understood on the basis of Kronig's theory of metallic dispersion as a result of the change of the lattice constant. Correlation with known values of the density changes leads to satisfactory agreement. WAT (1)

On the Electromotive Forces Generated by Friction between two Metals. Daizo Nuiyama. *Proceedings Physico-Mathematical Society of Japan*, Series 3, Vol. 14, Mar. 1932, pages 93-107.

Results of experiments on the e.m.f. between 2 metal pieces in contact and in relative motion are discussed. All metals were tested against a steel disk and it was found that each element acts in its own characteristic way towards the steel disk. In some cases the e.m.f. increases with the relative velocity while in others the e.m.f. reaches a maximum value at a certain relative velocity. The elements tried were C, Mg, steel, Co, Ni, Cu, Zn, Cd, Ag, Sn, Sb, Pb and Bi. The curves are reproduced. Ha (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

The Alloys of Silver, Copper and Zinc. *Metallurgist*, Jan. 1932, pages 5-7.

A correlated abstract with special attention to the work of Shuzo Ueno, reported in the Anniversary Volume, Institute of Chemistry, Imperial University, Kyoto, 1930, page 76. Ueno determined the physical properties of 2 series of alloys, one having a Zn content of 30% and the other containing only 10% Zn with varying ratios of Ag and Cu in each series. The series of alloys containing 30% Zn show a gradual increase in hardness with increasing Ag content, until the Ag reaches about 50%, at which stage the alloys have a β structure, and further additions of Ag result in a gradual lowering of the hardness. With the 10% Zn series the maximum hardness appears at 30% Ag, at which composition the alloys have a structure like that of the binary Ag-Cu eutectic. Malleability tests were made with alloys in the 10% Zn series only and indicated that alloys containing 10% Zn and 10% Ag are fairly malleable, but that the malleability falls off considerably when the Ag content is raised to 20 or 30%, while with an increase of Ag beyond that amount the malleability gradually increases. To test the corrosion in acid and in ammoniacal solutions the series of alloys with a constant Zn content of 30% was taken, and the results showed that the alloys most resistant to corrosion in these solutions have the composition corresponding to the ternary β solid solution in the Ag-Cu-Zn system. The corrosion of the ternary alloys, of the compositions tested, in HCl increases with the increase in Ag content until it reaches a maximum at 20% Ag where the alloys have the binary eutectic structure of Ag and Cu. Beyond this limit the addition of Ag makes the alloys more resistant to corrosion, until the maximum is reached at the Ag-Zn corner. This points to the fact that the α and β solid solutions are more resistant to corrosion than the eutectic. In the case of ammonia the attack is fairly uniform with alloys containing up to about 25% Ag, but there is a very considerable increase in corrodibility with 30% Ag. With increases of Ag content beyond this percentage there is again a marked decrease in amount of attack by ammonia. VVK (2)

Straight Copper-Lead Alloys versus Leaded Solid-Solution Bronzes for Heavy-Duty Bearings. F. R. Hensel & L. M. Tichvinsky. *Transactions American Society of Mechanical Engineers*, Vol. 54, Apr. 30, 1932, Iron & Steel, pages 11-24.

A metallurgical investigation of various bronze bearing metals and a comparative study of their bearing performance for use in heavy-duty bearings led the authors to the following conclusions: The Pb content and its distribution in straight Cu-Pb alloys depends primarily on the casting temperature; with lower temperatures quicker solidification takes place and a larger amount of Pb is retained in suspension. Pure Cu-Pb alloys have a tendency to pronounced Pb segregation if the Pb content exceeds 25%. Small amounts of impurities have an appreciable effect in retaining a good suspension of the Pb in the Cu and reduce the influence of the casting temperature on the Pb content and its distribution. The physical properties of straight Cu-Pb alloys are nearly independent of the casting temperature within the range of 1050°-1150° C. and depend only slightly on the Pb content within the limits of 12-25% Pb. The Brinell hardness decreases with increasing Pb content. The physical properties of straight Cu-Pb alloys have values about ½ those of solid solution bronzes of the same Pb content; the electrical conductivity is about 6 times as high, but is lowered considerably by small amounts of impurities, especially P and Sn. In general, a much better performance was obtained in bearing tests, the temperatures being considerably lower with straight Cu-Pb alloys than with solid-solution bronzes due to their higher heat conductivity and low friction coefficient. Bearings with steel backing can be made by a centrifugal casting process. Any speed between 1000 and 2000 r.p.m. may be used for a straight Cu-Pb bearing while a 2" to 3" diameter bearing of solid solution bronze should not run higher than 1500 r.p.m. All test data are given in detail and numerous micrographs show the influence of different methods of preparation. Ha (2)

Copper-Phosphorus Alloys with High Phosphorus Content. (Kupfer-Phosphorlegierungen mit hohem Phosphorgehalt.) A. Burkhardt, W. Linicus & G. Sachs. *Metallwirtschaft*, Vol. 11, June 10, 1932, pages 331-333.

Phosphorus forms a compound Cu_3P which contains 14.1% P and this forms an eutectic with Cu containing 8.3% P. The higher P alloys, up to 8.3% P, can be easily rolled and pressed above 300° C., but at lower temperatures they suddenly become brittle. The rolled alloys have better tensile strength and elongation than the cast alloys. The rolled 8% P alloy had a tensile strength of 55 kg./mm.^{2} and Brinell hardness of 230. Tensile tests, including elongation and reduction of area, were made on alloys containing 0 to 12% P at temperatures of -200° to +500° C. The test bars were cast and then hot rolled. The tensile strength of pure Cu decreases gradually with rising temperature while the ductility increases. With P additions the tensile strength is higher at low temperatures but falls off rapidly, becoming practically 0 at 500° C. The elongation and reduction in the higher P alloys start at 0 and increase very rapidly to about 100% at higher temperatures. In the 12% P alloy the reduction of area increases from 0 to 80% between 300° and 400°. Cu-P alloys of eutectic composition have been used as hard solders on account of their low melting point and high fluidity. Sheets, bars and tubes can be made from these alloys. The resistance of alloys with more than 8% P towards hot H_3PO_4 is very good. CEM (2)

Duralumin-alloys. (Duraluminlegierungen.) K. L. Meissner. *Berichte der 5. Internationalen Luftfahrttagung*, Haag 1930, Vol. 1, pages 836-850.

Report on the properties of duralumin. Definition of the expression "duralumin-alloys." Influence of aging at different temperatures on the properties of duralumin. Intended suppression of aging. Possibility of repeating aging. Increase in corrosion resistance by rolling on metallic coatings. Corrosion behavior of plated material. Reference to new tendencies in future development. GG (2)

A Note on the Tarnishing of Chromium-Plated Brass. W. M. PHILLIPS. *Transactions Electrochemical Society*, Vol. 59, 1931, pages 397-399.

Includes discussion. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 163. (4) 4

Rust Proofing of Iron and Steel. *Crushing & Grinding*, Vol. 1, Mar.-Apr. 1932, page 139.

"Parkerizing" and "Bonderizing" are described. Insoluble phosphates are not formed on Fe unless a di-H phosphate of the general formula $M(H_2PO_2)_2$, some free H_3PO_4 and some ferrous mono-H phosphate are present in the treatment bath. Such di-H phosphates may be prepared on a large scale and in a stable form without working in an inert atmosphere. Fe, Zn, Mn and Cd give the most suitable di-H phosphates. A mixture of Mn and Fe^{++} salts was best. The presence of small quantities of $Cu_3(PO_4)_2$ in the bath speeds up the reaction. Consumption of the phosphate in Parkerizing is 14-16 lbs./1000 ft.^{2} and in Bonderizing 11 lbs./1000 ft.^{2} The correct load in Parkerizing is 1 ft.^{2}/gal., for Bonderizing 1 ft.^{2}/2½ gal. The normal time for the latter is 10 min. AHE (4) 5

On the Corrosion Problem. (Zur Korrosionsfrage.) HANS HEBBERLING. *Bautechnik*, Vol. 10, Aug. 5, 1932, pages 436-437.

The paper deals particularly with the prevention of corrosion by the use of Cu steels and the protective action of minium. The various opinions as to the action of Pb_3O_4 are discussed. 7 references. GN (4) 6

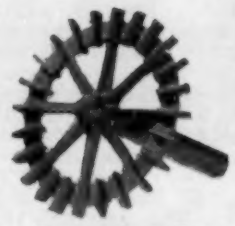
Corrosion Protection of Iron. (Korrosionsschutz für Eisen.) M. LEPINGLE. *Metallwaren Industrie und Galvanotechnik*, Vol. 29, Apr. 1931, pages 141-142.

The various protection means as vaseline and other fats, lacquers and metallic coatings (Cr, Zn, Sn, Pb, Cd) are dealt with. The effect of the metallic coatings is explained by means of the electromotive series of metals and the potentials of metals against 1/1 *N* solutions of their salts. Sn represents a poor rust protection in spite of its low tendency toward oxidation. Pb is usually out of question due to its softness and toxicity, while Cd acts as an excellent anti-rust coating. The most economical surface coating is galvanizing. Cd plating can only compete on account of the smaller metal consumption for plating purposes and due to its superior corrosion protection. Outdoor tests with a 0.0025 mm. layer showed a life time of 4-5 months, whereas no rusting was observed during 14 months, when a layer of 0.005 mm. was used. At the same current density, twice as much Cd can be deposited as Zn during the same period of time. EF (4) 7

New Method for the Protection of Precious Metals against Oxidation. (Das neue Verfahren zum Schutze von Edelmetallen gegen Oxydation.) H. MEYEN. *Deutsche Goldschmiedezeitung*, Vol. 35, Jan. 30, 1932, pages 54-55. 8

Experiences with Parabernol (composition not given), a lacquer-like substance for protecting precious metals against oxidation and air containing H_2S are discussed. The high resistivity against H_2S is preserved even after the Parabernol coating is removed. GN (4)

Protection of Steel and Iron Structures in Connection with Gas Manufacturing Plant. D. RITCHIE. *Gas Journal*, Vol. 199, Aug. 3, 1932, pages 254-255.



The article discusses the means of protecting Fe and steel from rust by moisture, S in various forms, sulphurous and sulphuric acids, and salt water. The paint used to protect pipes would be more satisfactory if more attention were paid to the priming coat. Berger's "Protmeum" contains Pb chromate and peroxide of Fe and orange Pb. It dries in from 6 to 8 hours and is easy to work. Fish oil is also a good ingredient in primers. Galvanized Fe requires a special type of primer. Semi-glass, the second step, is the undercoating paint. The finishing coat must be hard, tough, and impervious to water, H_2S and other fumes. Ti oxide mixed with Zn oxide produces an extremely durable paint. Al paint gives the best finish when applied by spray, although stippling is also satisfactory. It is a very popular finish for gasholders. A graphite paint gives an elastic, chemically inert paint which will not permit the passage of air or water and is not affected by sulphurous vapors. Chimneys of metal require a paint of graphite and a heat-resisting medium. Smoke-stack paint dries with a dull finish but gives maximum durability. MAB (4) 9 10

·ILLIUM·

RESISTS

Acetic Acid
Copper Sulphate
Ferric Chloride
Formaldehyde
Formic Acid
Lactic Acid
Nitric Acid (all strengths)
Oxalic Acid
Phosphoric Acid
Picric Acid
Silver Nitrate
Sodium Hydroxide
Sulphuric Acid (all strengths)
Tartaric Acid

and many other reagents

Pump Impellers and Housings

Valve Parts and Fittings

Spray Nozzles, Drying Equipment

Acid Handling Equipment

Every alloy has its place, but ILLIUM has many places. With few exceptions, it can be used satisfactorily and economically with any acid, alkali or salt in common use. Also, ILLIUM resists the *mixtures* and *impurities* so often encountered.

One of its most useful characteristics is resistance to oxidation at high temperatures. Dense, strong and tough, it withstands a surprising amount of heat, wear, impact or torque. Yet ILLIUM machines readily.

UNIVERSAL CORROSION-RESISTANT ALLOY

sold in form of castings, easily machined, takes high polish

ILLIUM castings, rough or finished, are made to your specifications in our modern foundry. Our engineers will quote from your patterns or drawings, or will work with you in *designing* ILLIUM parts suitable for your requirements.

Corrosion Stability of Ferrous and Non-Ferrous Metals and Alloys. (Korrosionsbeständigkeit von Eisen- und Nichteisenmetallen und -legierungen.) J. N. Friend. *Korrosion und Metallschutz,* Apr. 1932, page 92; *Die Metallbörse,* Vol. 22, May 28, 1932, page 675.

Report on 3 years tests with Pb, Zn, Sn, Al, Cu, Ni and various alloys of Fe, Cr, Ni, Cu and Zn exposed to sea-water attack in the docks of Southampton. Fine-grained brass proved to be superior to coarse-grained material. A 70/28 Ni-Cu alloy displayed remarkable corrosion stability. High grade Zn and Sn are less susceptible to corrosion than lower commercial brands. Additions improve the corrosion resistance of Cu. Drawing, riveting and cold working do not materially influence the corrosion of Ni and Cr steels in contrast to welding. Maritime fauna do not affect corrosion while alive. Dead mussels favor local pittings on alloyed steels, Ni and low Cu bearing Ni alloys. Alloyed steels displayed relatively good corrosion stability, but former investigations were confirmed that these steels are liable to corrode locally. EF (4)

On the Dissolution of Metals in Acids. J. N. Brönsted & N. L. Ross Kane. *Journal American Chemical Society,* Vol. 53, Oct. 1931, pages 3624-3644.

This investigation studies the dissolution of sodium from sodium amalgam in acid, alkaline, buffered and nonaqueous solutions with a view to interpret the mechanism of the reaction. MEH (4)

Sulfuric Acid vs. Metals. H. E. Searle & R. Worthington. *Bulletin T-3, International Nickel Company,* pages 2-12.

The corrosion effects of H_2SO_4 under various conditions are explained and its action particularly on Monel metal and other Ni alloys discussed. The methods of measurement of corrosion are briefly explained; it is usually expressed in average weight loss in mg./dm.^{2} of area per day or the average penetration of a surface per year in inches when continuously exposed to the corrosive, that is, the average decrease in thickness over the whole surface of a metal sheet on one side. The results of tests on several metals are reproduced in curves. Monel withstands the corrosive effect of dilute H_2SO_4 and is used for pickling tanks and crates. The galvanic and concentration cell corrosion is explained and the order of metals according to their forming galvanic couples given, with Al on the anodes (corroded) end to Ag solder on the protected (cathodic) end. A table of physical properties of some corrosion-resisting metals in the form of annealed rolled bars is added. An appendix deals with derivation, properties and uses of H_2SO_4. Ha (4)

Oxygen Effect on H_2S Gas Corrosion. John M. Devine, C. J. Wilhelm & Ludmig Schmidt. *Oil & Gas Journal,* Vol. 30, Apr. 7, 1932, pages 16-86.

The Handling of Corrosive Gases. Thomas H. Chilton & William R. Huey. *Industrial & Engineering Chemistry,* Vol. 24, Feb. 1932, pages 125-131.

Gases are corrosive at ordinary temperatures only in the presence of moisture. Resistance to moist gaseous corrosive agents can be obtained in the same way as resistance to the same agents when dissolved in water, and available materials and methods for the common cases are listed. Direct gaseous attack at high temperatures is of 2 types: surface compound formation and disintegration. Some principles are laid down for resistance to surface attack. Metals and alloys for resistance to high-temperature attack are listed from several sources. 23 references. MEH (4)

Wear of Grates by the Heat Effect of Upper Silesian Fuels. (Rostverschleiss durch Wärmeeinfluss bei oberschlesischen Brennstoffen.) P. Fuchs. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Jan. 1932, pages 7-9.

The paper studies the effect of higher temperatures on the deterioration of 8 cast Fe grates. The variations of chemical composition were considerable, as the following table shows:

	Si %	Mn %	P %	S %	C %
Mean value of the 8 grates	1.72	.53	.67	.11	3.31
Suggested composition by D I N	1.0–2.0	.5–.8	<.3	<.08	3.5–4.0
Maximum values among the 8 grates	2.12	.84	1.06	.18	3.60
Minimum values among the 8 grates	.95	.33	.37	.07	2.95
Difference between maximum and minimum composition	1.17	.51	.69	.11	.75

The prime cause of wear is the decarburization and subsequent scaling due to too high temperatures on the grate. High temperatures on the grates are caused by improper adjustment of grate and fuel. The chemical attack of slags does not bring about considerable wear. However, the physical behavior of slags considerably increases the wear. Standardization of the chemical composition of grates is suggested. The above-mentioned results are substantiated by practical experiences which demonstrate the relations between chemical composition, arrangement of the grates and fuel on its wear. 3 references. OWE (4)

Metal Losses in Condensers and Tried Methods for Combating Corrosion. SHERMAN S. SHAFFER & JOHN POLLOCK. *Oil & Gas Journal,* Vol. 30, Mar. 31, 1932, pages 78-80.

A general discussion of the corrosion of condensers in the oil industry. Data are given showing that, in regard to the cooling water used, salt water is most corrosive and temperature and oxygen content increase the rate of corrosion. Internal corrosion will vary with the type of crude oil and the kind and treatment of the various fractions. External protection can be partially effected by the use of contact Zn or the addition of such substances as dichromate and silicate to the cooling water. The most effective internal protection is the use of ammonia. As regards corrosion-resistant metals, a few ferrous alloys tested in the stream from distillation of acid treated naphtha showed that metals of the 18-8 Cr-Ni type show good resistance; low Cr steel shows only low resistance to this type of corrosion. An alloy cast Fe of the following composition: Ni 12-15%, Cr 3-4%, Cu 5-7%, Si 1.5%, total C 3% has proved very resistant in such a service. Cast Fe on account of its low cost and moderately long service, is reasonably economical, but a trial of the above alloy may justify the higher capital expenditure. The authors summarize as follows: "After consideration of the various means for obtaining longer life from condensing equipment, it appears that ammonia will prove the most satisfactory chemical for this purpose and its use in conjunction with cast iron will in all probability be preferred over that of corrosion resistant alloys involving high capital expenditure." VVK (4)

Corrosion of Mild Steel and Alloys by Hydrogen Sulfide at 500° C. and Atmospheric Pressure. A. WHITE & L. F. MAREK. *Industrial & Engineering Chemistry,* Vol. 24, Aug. 1932, pages 859-861.

Mild steel is rapidly attacked by H_2S at 500° C. and atmospheric pressure. Under the same conditions, Al is very slightly attacked even after exposure for 3 weeks. High Cr steels (12 to 20% Cr) resist the corrosion, and the resistance increases with increase in the Cr content. The presence of high proportions of Ni are detrimental to the corrosion resistance imparted to the alloys by Cr. 8 references. MEH (4)

An Interesting Example of the Internal Corrosion in Brass. (Ein interessantes Beispiel für die innere Korrosion von Messing.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 7, 1932, page 314.

Abstract of the paper by G. Mandrau in *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, June 1931, pages 293-294. See *Metals & Alloys,* Vol. 3, July 1932, page MA 204. GN (4)

Corrosion Tests on Condenser Tubes. *Transactions American Society of Mechanical Engineers, Section Fuels & Steam Power,* Vol. 53, 1931, pages 247-251.

This is a report of tests made by A.S.M.E. Special Research Committee to determine the extent of the influence of air on tube material. The method used was to make comparative corrosion tests with solutions saturated with air and under vacuum. The solutions were KCl in various concentrations with Admiralty brass anodes and Cu cathodes; the loss of brass was determined and represented in curves. It can be clearly seen that the loss in solutions saturated with air is almost twice that under vacuum. A few special cases of corrosion are discussed. Ha (4)

Corrosion of Bronzes by Vinegar. E. M. MEAK & J. C. LEROUX. *Industrial & Engineering Chemistry,* Vol. 24, July 1932, pages 797-799.

8 bronzes and their chief components (Cu, Sn and Pb) were exposed to still, aerated, and sprayed vinegar. All the metals tested, except Sn, corroded most in the spray tests and least in the immersion tests. Sn corroded most in the aerated vinegar and least in the spray tests. Pb corroded more rapidly than any other metal tested. All bronzes tested corroded sufficiently under all conditions used to cause considerable contamination of the vinegar with heavy metals. MEH (4)

Effect of Cold-Rolling and Annealing on Solubility of Cartridge Brass in Chromic Acid. JOSEPH D. PARENT. *Industrial & Engineering Chemistry,* Vol. 24, Mar. 1932, pages 318-320.

12 references. It is concluded from this study that the grain size in itself gives no indication of the corrosion loss to be expected, and that the important factors are inner stresses, chemical homogeneity, physical homogeneity and orientation of the grains. MEH (4)

Long Time Tests on the Corrosion of Condenser Tubes Under Service Conditions. (Dauerversuche über die Korrosion von Kondensatorrohren im Betrieb.) P. REUTER. *Elektrizitätswirtschaft,* Vol. 31, Jan. 31, 1932, pages 6-13.

The failure of 50,000 condenser tubes in 12 different condenser units after 12,000 service hours precipitated this investigation which refers to 414 tubes picked out as samples. The order of merit of the various material, which were furnished by 9 different manufacturers, showed the following results with respect to the best corrosion resistance: (1) 70.55% Cu, 28.13% Zn, 1.01% Sn, 0.03% Fe, 0.04% Ni and traces of As, Pb, S. (2) 69.78% Cu, 29.13% Zn, 0.99% Sn, 0.02% Pb, 0.03% Fe, 0.05% Ni and traces of As and S. (3) 84.74% Cu, 14.92% Ni, 0.24% Mn, 0.03% S and traces of Zn. (4) 98.68% Cu, 1.26% Sn and traces of Sb, As, Pb, Fe, S, Zn. (5) 70.61% Cu, 28.36% Zn, 0.96% Sn, 0.03% Pb, 0.04% Fe and traces of As and S. (6) 96.77% Cu, 2.92% Al, 0.26% Zn. 0.01% Fe and trace of S. (7) 53.80% Cu, 38.25% Zn, 4.74% Ni, 1.28% Mn, 0.94% Al, 0.82% Fe, 0.15% Sn, 0.14% As, 0.10% Pb and traces of Sb and S. (8) 70.57% Cu, 29.34% Zn, 0.05% Fe, 0.02% Pb, 0.016% S, 0.006% Sn and trace of As. (9) 69.37% Cu, 29.60% Zn, 0.96% Sn, 0.04% Fe, 0.03% Pb and traces of As and S. Microstructural investigations revealed that the coarse grained material withstood the corrosion attack to a greater degree than the fine crystalline tubes which is contrary to the observations of other investigators. Tests were conducted with mercury nitrate, but it was proved that internal stresses did not play an essential role in failure. Testing for physical properties (tensile strength, elongation, Brinell Hardness) did not yield a clue either. The widely different behavior of the same type of brass alloys is ascribed to non-metallic inclusions, mainly oxides. EF (4)

Over 28 Major Industries use Duriron for more than 131 Corrosives!

Chemical manufacturers . . . petroleum refineries . . . dyes, paints and pigment manufacturers . . . pulp and paper mills . . . pickling and plating industries . . . explosive manufacturers . . . food processing plants . . . textile bleachers and dyers . . . silk weighters . . . and a host of others use Duriron pumps, valves, pipe and fittings, kettles, jets, ejectors, special castings and special equipment in their processes.

With Duriron, they handle an impressive list of corrosives, from Acetic Acid to Zinc Sulphate.

Duriron isn't resistant to every known corrosive—hydrofluoric acid, for instance—and no such claims are made for it. But it is remarkably resistant to a surprisingly large number.

By using Duriron equipment, many manufacturers have been enabled to reduce costs tremendously, and even in some special cases to use a process that otherwise couldn't have been considered.

We don't know, of course, that Duriron would be satisfactory in your case, but we are willing to give you the benefit of our twenty years of experience in dealing with corrosion problems exclusively.

Please feel free to consult us—all information that you may give us will be considered strictly confidential. A trained Duriron representative is located near you, and he will be glad to be of personal service.

STRUCTURE OF METALS & ALLOYS (5)
Structure & X-Ray Analysis (5b)

The Crystal Structure of Electrodeposited Alloys. Silver-Cadmium. CHARLES W. STILLWELL. *Journal American Chemical Society,* Vol. 53, June 1931, pages 2416-2417.

The crystal structures of Ag-Cd alloys, ranging in composition from 20 to 96% Cd, have been obtained from X-ray diffraction data. The alloys were deposited at room temperature according to the Stout method using a current density of one ampere. In general, the structures of the alloys are quite different from those of thermal alloys of corresponding composition which have been brought to equilibrium before examination. MEH (5b)

The Crystal Structures of Electrodeposited Alloys. An X-Ray Diffraction Study of Silver-Cadmium Deposits. CHARLES W. STILLWELL & LAWRENCE E. STOUT. *Journal American Chemical Society,* Vol. 54, July 1932, pages 2583-2592.

Presented at the Buffalo meeting of the American Chemical Society, Sept. 1931. The most significant points brought out by this study are: 1. Every deposit consists of solid solutions or compounds. In no case is the deposit merely a mixture of Cd and Ag. 2. The phase stable in a given range of composition of the thermal alloys is the predominant phase in an electrodeposited alloy in that same composition range. 3. In general the deposits are heterogeneous, containing appreciable amounts of phases which do not exist in an annealed alloy of the composition in question. 4. There is little evidence indicating the formation of a metastable deposit under the conditions of the experiment. MEH (5b)

Hyperfine Structure of Lead. KIYOSHI MURAKAWA. *Scientific Papers Institute of Physical & Chemical Research,* Tokyo, Vol. 18, May 1932, pages 191-204.

Each line of the ordinary Pb spectrum consists of 2 lines of about the ratio 2:1 and fainter lines of ratios 2, 3 or 4. All observed hyperfine structure of the Pb spectrum can be interpreted by assigning the nuclear moments 0, ½. 0 to Pb_{208}, Pb_{207} and Pb_{206} respectively. The spectroscopic data give as the ratios of mixtures of ordinary Pb isotopes the values: $Pb_{208} : Pb_{207} : Pb_{206} = 47.7 : 25.9 : 26.4$. Ha (5b)

Studies upon the Widmanstätten Structure, I.—Introduction. The Aluminum-silver System and the Copper-silicon System. ROBERT F. MEHL & CHARLES S. BARRETT. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 78-122.

Includes discussion. See *Metals & Alloys,* Vol. 1, Dec. 1930, page 908. (5b)

Radiological Methods of Testing Structures. V. E. PULLIN. *Steam Engineer,* Vol. 1, June 1932, pages 375-377. X-ray examination of metal products is discussed. AHE (5b)

An X-ray Examination of Iron-Chromium Alloys. G. D. PRESTON. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Ser. 7, Vol. 13, Feb. 1932, pages 419-425.

Scientific investigation for the accurate determination of the parameter changes which take place in the series of solid solutions. RHP (5b)

Hyperfine Structure of Mercury. V. KIYOSHI MURAKAWA. *Scientific Papers Institute of Physical and Chemical Research,* Tokyo, Vol. 18, May 1932, pages 177-190.

The hyperfine structure of Hg lines in the ultra-violet region is investigated. All lines are interpreted, without exception, by assuming the nuclear moments 0, ½, 3/2 for even isotopes, Hg_{199}, Hg_{201}, and by the intensity rules for the hyperfine structure multiplet. Ha (5b)

Utilization of the Radioactive Occurrences in Industry. III. Physical Investigations with Radium Rays. (Verwertung der radioaktiven Erscheinungen in der Technik. III. Physikalische Untersuchungen mit Radiumstrahlen.) H. W. FLEMMING. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, June 5, 1932, page 302.

Abstract of the following papers before the 37th annual meeting of the Deutschen Bunsengesellschaft. N. Riehl: Testing materials with γ-rays (with special reference to the testing of welds) K. Przybram: Radium rays as resource for the physico-chemical investigation of solid bodies. P. M. Wolf & N. Riehl; On the production of active deposit of thorium with high output. GN (5b)

X-Ray in the Aluminium Industry. N. C. HYPHER. *Metallurgia,* Vol. 6, Aug. 1932, pages 115-117.

Discusses usefulness of radiography in the Al alloy industry. Equipment and technique are described and several radiographs are shown. JLG (5b)

A Universal X-Ray Apparatus for Crystal Investigations. (Eine Universal-Röntgenapparatur für Kristalluntersuchungen.) H. BRAEKKEN. *Zeitschrift für Kristallographie,* Vol. 81, Feb. 1932, pages 309-313.

The outstanding features of a "universal" X-ray equipment are defined in the introduction. The essential part of the writer's apparatus is based on the goniometer of Weissenberg, improved by Böhm. The applicability and convenience has been greatly improved. The whole apparatus is built around a steel cylinder used as pre-vacuum container. The X-ray tube, a metal porcelain tube of the Siegbahn type, is on top of the pump. 3 different apparatuses can be mounted around the X-ray tube at the same time. The goniometer is provided with a removable optical device, thus representing a complete optical double circle goniometer. The axis carrying the mounted crystal can be revolved freely by an auxiliary screw. The rotation axis of the aperture system is perpendicular below the crystal. The main goniometer axis, the axis of the optical part, the axis of rotation and the axis of the aperture system intersect in the crystal. Thus photographs can be taken at different angles without changing the crystal's position. The film carrier is constructed in such a manner as to waste only a small angle range and to use films of various lengths. The translation ratio between the crystal rotation angle and the translation of the film can be adjusted to 3 values. A special plate carrier is employed for Laué photographs. Readjusting of the crystal is not necessary. EF (5b)

X-Ray Inspection of Welded Joints. H. R. ISENBURGER. *Steel,* Vol. 88, Apr. 30, 1931, pages 31-34, 38.

See "Radiographic Inspection of Materials," *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 62. Ha (5b)

Gamma Rays and their Uses. GILBERT E. DOAN. *Welding Engineer,* Vol. 17, Jan. 1932, pages 31-32.

The convenience of using radium as a source of γ rays for inspection of welds is explained and illustrated. Ha (5b)

Tables of Cubic Crystal Structure. I. E. KNAGGS, B. KARLIK & C. F. ELAM. Adam Hilger Ltd., London, 1932. Cloth, 6½ x 10 inches, 90 pages. Price 11s 6 d.

The aim of this book has been the collection of the available information, which has hitherto been scattered through the scientific journals of the world, in a convenient form. In each section the information is contained in the sets of tables of which the first gives the substances in alphabetical order, with their chemical formulae and index numbers in the succeeding tables and bibliography, the second gives the substances in order of lattice spacing and includes remarks, while the third is a full bibliography. It is of interest to note that the bibliography to the first section extends to more than 800 references and that to the second contains 126 references. A useful feature is the inclusion of several pages for notes in extension of the work.

This book should be of the greatest assistance to workers who practice X-ray methods of crystal analysis of powders and of separate crystals and should go far to encourage the extended use of X-ray methods for chemical analysis by releasing for general and ready use information whose scattered distribution has rendered it difficult of access. Constituents of Aluminum-iron-silicon Alloys. WILLIAM L. FINK & KENT R. VAN HORN. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 383-395.

Includes discussion. See *Metals & Alloys,* Vol. 1, Dec. 1930, page 907. (5b)

Constitution of High-purity Aluminum-titanium Alloys. WILLIAM L. FINK, KENT R. VAN HORN & P. M. BUDGE. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 421-439.

Includes discussion. See *Metals & Alloys,* Vol. 2, May 1931, page 98. (5b)

The Structure of Extremely Thin Crystal Layers. (Über die Struktur extremdünner Kristallschichten.) F. KIRCHNER. *Die Naturwissenschaften,* Vol. 20, Feb. 12, 1932, pages 123-124.

Structural investigations by electron interferences were accomplished on crystal layers prepared by sublimation or evaporation in vacuum. Chaotic orientation is only met with in thin layers deposited on a glass carrier if the grain is exceedingly minute. A regular arrangement begins at a grain size of about 10^{-6} cm. Some experiments refer to depositions of metallic layers on celluloid, collodium and mica. The crystal arrangement parallel to the carrier fluctuated depending on the metal deposited and on the nature of the carrier. EF (5b)

The Structure Types of Steel on the Basis of Formation of the Atom Lattice or Grating. (Die Gefügeformen des Stahles, Gedeutet aus dem Bau des Atomgitters.) HEINRICH HANEMANN. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 621-624.

From a crystallographic study of the transformation or conversion of the γ-solid solution in ferrite, pearlite, and cementite, as well as of the cementite crystallization in the formation of tertiary cementite according to the arrangement of the diffusing atoms in the space lattice, 3 separate classes of diffusion may be differentiated: (1) The perfusion, in which the migrating atoms are shifted or displaced to straight lines without displacing other kinds of atoms; (2) the concentric diffusion, in which atoms migrate with other classes of atoms to the nucleus positions of the new type of crystal through lattice pores and voids or position change; (3) the parallel diffusion, in which the direction movement of a large number of diffusing atoms is parallel or in line. The γ- and α- Fe are differentiated by the way in which the carbon migrates. In the γ-solid solution the carbon migrates by perfusion and at high velocity, while in α- Fe its motion is by diffusion with decreased velocity. Slices of steel samples, located in planes perpendicular to each other, having very large grained "Widmannstätten" structure were prepared and the inclination of the ferrite layers to each other was determined. It is evident that the ferrite of "Widmannstätten" structure principally forms layers in octahedral planes, only rarely in correlated cubic surfaces. Other directions of precipitation for ferrite were not encountered. DTR (5b)

X-Ray Radiography of Boilers with Special Reference to Welding Technique. (Die Röntgendurchstrahlung im Dampfkesselbetrieb unter besonderer Berücksichtigung der Schweisstechnik.) C. KANTNER & A. HERR. *Zeitschrift des Bayerischen Revisionsvereins,* Vol. 35, July 15, 1931, pages 149-152; July 31, 1931, pages 175-180; Aug. 15, 1931, pages 188-191; Aug. 31, 1931, pages 203-205.

The paper first outlines the principles of radiography as applied to boilers while in use. The largest part of the paper is given to the results of practical examinations as they were carried on by the Schweisstechnische Versuchsanstalt der Deutschen Reichsbahngesellschaft at Wittenberge. Fire boxes, boiler plates, various parts of boilers, boiler fittings and auxiliary equipment were examined. The apparatus used is described. The economy of radiography is discussed with special reference to the capacity and cost of operation. Radiography proved suitable for the X-ray examination of boilers. The safety in operation as well as the reliability in processing boilers and auxiliary equipment can be increased by X-raying so that accidents can be avoided by a careful continuous supervision. 18 references. GN (5b)

New Method of Testing Cast or Welded Pieces. (Nouveau procédé de controle des pieces coulées ou soudées.) HOLWECK. *L'Usine,* Vol. 41, June 3, 1932, page 31.

The principles of testing by X-rays, γ-rays, the properties of these radiations and the manner of their application are briefly explained. Ha (5b)

Both Micrograms are Slightly Reduced to Suit Advertising Space

THE LEITZ WORKS now offer for Micro-Metallograph "MM-1" and "MM-2" a novel darkfield illumination device and a series of objectives, contributing very materially to the efficiency of microscopical diagnosis of metal structures. These new products make possible a much more positive revelation and study of characteristic details which until now could not be observed.

THE POSITIVENESS with which the structure is revealed under Darkfield makes it extremely useful in research work for studying new alloys as well as in rechecking observations made in Brightfield. One of the most striking features of Darkfield observation and photomicrography is the extreme contrast coupled with maximum detail. It is practically impossible to obtain a Darkfield photomicrograph of mediocre contrast and the oblique illumination from all sides reveals to the best advantage all the intimate details of the surface being examined and this in a manner impossible to effect with the same degree of control by means of Brightfield illumination.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Technical Methods of Photo-elastic Research. (Technische Methoden photoelastischer Forschung.) R. V. Baud. *Schweizerische Bauzeitung,* Vol. 100, July 2, 1932, pages 1-3; July 9, 1932, pages 15-20.

The paper discusses the technical side of photo-elastic research with special reference to simple and rapid methods. A historical survey is given first on the photo-elastic methods developed so far and their possibilities of application. Those discussed at length are (1) the method of the sensitive color, (2) the photographic method, (3) the Coker compensation method. Some examples on the fields of principal stresses are considered. The more complicated methods of directly determining the principal stresses are also discussed. 26 references. GN (6)

On the Resistance to wear of Rail Heads. (Ueber die Verschliessfestigkeit der Schienenköpfe.) *Stahlbautechnik,* Supplement to *Montanistische Rundschau,* Vol. 24, June 16, 1932, page 8.

Abstract from a report of the Vienna Municipal Testing Laboratory. *(Mitteilungen der Wiener Städtischen Prüfungsanstalt für Baustoffe,* Report 1, 1932). The paper deals with the increase of the wear resistance of rail heads of sorbitic structure, describes the various types of testing machines (Spindel, Amsler, Mohr and Federhaff) and discusses experiences with sorbitic rails in various countries. The importance of the chemical composition and a sufficiently high yield point is pointed out. GN (6)

The Torsion Problem of the Eccentric Circular Ring. (Das Torsionsproblem für den Exzentrischen Kreisring.) E. Weinel. *Ingenieurarchiv,* Vol. 3, Mar. 1932, pages 67-75.

For the eccentric circular tube which is subjected to torsion, the torsion functions, the drilling moment and the maximum shear stresses have been determined and are discussed in accordance with the methods as they have been used by A. Föppl and L. Föppl. It is shown that the formulae on the maximal shear stress given by Macdonald (Torsional strength of a hollow shaft, *Proceedings Cambridge Philosophical Society,* Vol. 8, 1893, page 62) do not hold true. The formulae have been revised, numerical results are given. 4 references. GN (6)

On the Relation between Stresses and Deformation in the Work Hardening Range. (Ueber den Zusammenhang von Spannungen und Formänderungen im Verfestigungsgebiet.) R. Schmidt. *Ingenieurarchiv,* Vol. 3, June 1932, pages 215-235.

This is an extensive experimental investigation on the laws of plastic deformation carried out at the Institute for Applied Mechanics of the University of Göttingen. A specially built Losenhausen tension-torsion machine was used which permits the study of the flow of metal under the simultaneous influence of tension and torsion. The deformation was measured with a specially designed apparatus for simultaneous measurement of torsion and elongation. Low C steel tubes and Cu tubes of small wall thickness were tested in order to guarantee a homogeneous state of stress. The tests comprise (1) Combined tension-torsion flow tests without intermittent load lifting on steel tubes. (2) Alternating tension-torsion tests with intermittent load lifting. (3) Pulling tests on light low C steel plates, alternating in longitudinal and transverse direction. (4) Torsion tests on steel tubes with alternating direction of torsion. 8 references. GN (6)

Wear Tests on Automobile Gears. (Verschleissversuche mit Zahnrädern für Kraftwagen.) Rist. *Zeitschrift des bayerischen Revisionsvereins,* Vol. 36, Aug. 15, 1932, pages 177-178.

Abstract of paper by M. Ulrich in *Mitteilungen aus der Materialprüfungsanstalt der Technischen Hochschule Stuttgart,* Report No. 4, 1932, 95 pages. The tests comprised: (1) running tests on single gears with stable bearings and increasing the gear load by steps. Alloyed and unalloyed case carburizing steels of German, Austrian, Czecho-Slovakian and American make were used. (2) Running tests on complete automobile gear sets of German and foreign heat treated steels. (3) Cyanided single gears of German, Austrian and American heat treated steels tested as under (1). (4) The same steels as under (3) tested as group (2). (5) Shifting tests on alloyed case-carburizing steels, heat treated steels and cyanided heat treated steels. The wear was tested by 3 methods, by means of an optical gage, by determining the total weight loss. The results show that the corresponding steels of various manufacturers are quite similar. Group (1) showed the best results. Heat treated steels wear more. Cyanided heat treated steels show less wear than non-cyanided steels. This is shown on single gears as well as whole gear sets. As to the wear of gears in violent shifting it was found that the wear of case-carburizing steels is in part somewhat higher than that of cyanided and non-cyanided heat treated steels. For chemical composition, heat treatment, mechanical properties of the steels and gears used in the tests and the detailed results the original paper must be referred to. GN (6)

The Question of Stress in the Repeated Impact Test. (Zur Frage der Beanspruchung beim Dauerschlagversuch.) A. Thum & S. Berg. *Mitteilungen der deutschen Materialprüfungsanstalten,* No. 12, 1932, pages 180-182.

See *Metals & Alloys,* Vol. 1, Oct. 1930, page 796. HWG (6)

The Relation between Rockwell and Brinell Hardness. *Metallurgist,* July 1931, pages 110-111.

Testing of Automobile Steels. (Die Prüfung von Automobilstählen.) *Stahlbautechnik,* Supplement to *Montanistische Rundschau,* Vol. 24, Aug. 16, 1932, page 8.

Abstract of a paper in *Mitteilungen der Städtischen Prüfungsanstalt des Wiener Magistrates.* The importance of the notched impact test is emphasized. Dynamic tensile tests are also of importance in testing automobile steels. GN (6)

Theoretical and Experimental Investigations on the Torsion of Box Sections. (Theoretische und experimentelle Untersuchungen zur Torsion von Kastenquerschnitten.) S. von Bouteville. *Forschung, Zeitschrift Technische Mechanik und Thermodynamik,* Vol. 3, Jan./Feb. 1932, pages 25-42.

1 After some introductory remarks on the use of box sections, previous solutions on the determination of the torsion of loaded box sections are discussed. A new approximate method is developed for the calculation of the torsional stresses in thick-walled box sections. The method can also be applied to other hollow sections. In the method the box is subdivided in single plates the deformations and stresses of which are investigated. The solution, in comparison with the most frequently applied approximate solution for thin-walled box sections shows that an additional correction is necessary for both the resistance to twist and the torsion stresses. Measurements on 5 various symmetrical box sections of annealed cast steel confirm that the theory holding true for thin-walled box sections when applied to thick-walled box sections gives errors of 30% and more. However, the deviation of the testing results from the newly developed approximate theory on thick-walled box sections generally does not exceed 10%. The formulae developed are to be used also for unsymmetrical box sections, double-symmetrical box sections, and square-shaped box sections. The method of investigation is applicable to other hollow shapes composed of rectangular sections. 15 references. GN (6)

Dependence of the Damping of materials upon the Magnitude and Speed of Deformation. (Die Abhängigkeit der Werkstoffdämpfung von der Grösse und Geschwindigkeit der Formänderung.) E. Bankwitz. *Mitteilungen des Wöhler-Instituts,* Heft 11, 1932, 53 pages.

Torsional damping tests, which included rise of temperature determinations, were made on 3 low and medium C steels, on Cu, commercial Al alloys, a cast brass of unstated composition, 2 Al alloys and elektron. Some of these materials have endurance limits above the static yield point, and on account of thermal conductivity, thermal measurements of damping at low deformations are difficult. The experiments were aimed to produce data on the first part of the damping curve. The results are expressed in formulae, tables and curves which do not lend themselves to abstracting. Bankwitz believes that he has smoothed out some of the discrepancies of earlier work. HWG (6)

Vibrations in Freely-swinging Wires and their Damping. (Schwingungen an Freileitungsseilen und ihre Dämpfung durch Resonanzschwingungsdämpfer.) F. Puritz. *Mitteilungen des Wöhler-Instituts,* Heft 12, 1932, 67 pages.

Resonance in conductor wires, and in the system-conductor and pole or mast was studied experimentally on a small scale and the results applied to large scale work. Rubber damping devices, spring suspensions of both steel and Cu and various methods of suspending the cable from the mast were studied. Suitable damping devices cut down the amplitude of vibration very markedly. HWG (6)

On the Elastic Extension of Metal Wires under Longitudinal Stress.—Part 2. Experimental. L. C. Tyte. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Ser. 7, Vol. 13, Jan. 1932, pages 49-69.

An extended research to measure deviations from Hooke's law. Materials investigated were steel, Fe, Ni, brass, Cu, Al, Zn, Sn and Pb, some of them being examined after different heat treatments. All metals investigated showed deviation over the whole experimented range. The deviation differs widely for different materials and for the same materials with different treatments. For annealed metals the deviation increases with increase of crystal size. RHP (6)

Basis for the Testing and Grading of Rolling Hardness of Cold Rolled Low Carbon Strip Steel. (Unterlagen für die Prüfung und Walz Härtenstaffelung von Kaltgewalztem Kohlenstoffarmen Band Stahl.) Anton Pomp & Fritz Winterhoff. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 14, Report 197, 1932, pages 11-24.

For a long time it has been customary to assign terms to the various degrees of hardness of cold rolled material. The German method of designating amount of hardness generally could be classified in 6 different ranges, running from dead annealed to completely hard. The individual ranges were wide and not definitely limited, one hardness range almost always overlapping other ranges. This present study was undertaken to standardize and define hardness in cold rolled low-C band or strip steel. A series of strip samples, analysis of 0.12% C, 0.55% Mn, 0.017% P, 0.019% S, trace Si, in thicknesses of 1.5, 1, and 0.5 mm., and annealed at 670° and 920° C. were given increasing amounts of cold roll reduction from 0 to 75%. The elongation, yield point, tensile strength, hardness, penetration and structure examination were made of original, intermediate and final material. The original strip sheets were produced from slabs 40 mm. thick, heated in a semi-gas furnace to 1250° C., broken down and hot rolled on a strip mill to strips 130 mm. wide and 4 mm. thick. Tensile strength test made in center and on 2 sides in an Amsler test machine; hardness by Rockwell (B) 1/16" steel ball 100 kg. load; bend test by Tarnogrocki, forward and backward bends of 180° = 1 bend; penetration by both Erichsen and Guillens methods. The old and new methods of defining amount of hardness together with ranges of physical properties for each are given, starting with annealed material. In addition a mathematical method is given by following equation based on test data: $h_0 = \frac{h_1}{1 - \frac{w}{100}}$, where h_0 is the required thickness of original strip sheet after annealing subsequent to hot rolling, h_1 is finished strip thickness desired, w is % reduction in thickness or necessary amount of cold roll reduction. A complete chart was made from the equation for every range of hardness and it is possible to pick out original strip sheet thickness to produce any range of hardness for any desired finished gage strip steel. The applications of each of the 8 ranges of hardness are explained as to the use intended for the material. DTR (6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A.S.T.M. Research Committee on Fatigue of Metals.

The Elastic Limit of Metals. (La Limite Elastique des Metaux.) PIERRE VERNOTTE. *Chimie et Industrie,* Vol. 27, Apr. 1932, pages 765-769. 1

The author considers the methods used in Germany for determining the fatigue limit by short-time methods are unsatisfactory. One method, based on the heat effect under rotary bending, did not show satisfactory results. Another, based on change in rate of deflection, seems to be based on phenomena not related to fatigue and results in an early generalization of now doubtful experiments. The author distinguishes between deformation resulting from variations in physico-chemical structures and deformation resulting from purely mechanical effects, e.g.: (1) Irreversible, non-permanent deformation, dependent on variations in the structure, which in turn are dependent on the stress-cycle, but show a time lag; it initiates with the slightest stress-cycle. (2) Eventual, irreversible, permanent deformation, dependent on variations in structure, effected generally with a certain time lag, but irreversibly dependent on the stress-cycle; it initiates when this cycle reaches a certain degree. (3) Irreversible, permanent deformation, almost instantaneous, but originating from purely mechanical causes, starting at a generally higher value in the stress-cycle. Deformation of metals, then, to a great extent depends on the law of applied force versus time, but the true elastic limit would not depend on it. It would be difficult to distinguish experimentally between these 2 limits: the limit of permanent reactivity and the true elastic limit. In numerous simple cases, particularly if the structure is sufficiently homogeneous, the fatigue limit should be identical with the true elastic limit. The author discusses the theory of fatigue at high temperatures. MAB (61) 2 3

Fatigue Strength and Strain Relief. CHAS. H. JENNINGS. *Welding Engineer,* Vol. 17, Feb. 1932, pages 39-41, 58; Mar. 1932, pages 38-39. 4

Data on the properties of welds and welded joints are given derived from tests which make possible finding a scientific basis for the design of welded structures. See "The Relief of Welding Strains by Annealing," *Metals & Alloys,* Vol. 2, Dec. 1931, page 310. Ha (6f)

Corrosion-Fatigue. *Metallurgist,* Jan. 1932, pages 11-13. 5

Extended abstract of paper by Inglis and Lake in Transactions Faraday Society, Vol. 27, Dec. 1931, on "Corrosion-fatigue Tests of Mild Steel and Chromium-nickel Austenitic Steel in River Tees Water." See *Metals & Alloys,* Vol. 3, May 1932, page MA 128. VVK (6f)

The Practical Application of the Microscope in Railway Service. FREDERICK H. WILLIAMS. *Engineering Journal,* Vol. 14, Nov. 1931, pages 558-563; discussion Dec. 1931, page 608.

Microscopic examination of the material involved in the fracture of machine and structural parts has been found of very great value, and this paper gives illustrations of a number of typical failures, principally in locomotive work, and discusses their probable causes, with special reference to the occurrence of failure from fatigue cracks. VVK (6f) 6

The Endurance Impact-Bending Test. (Der Dauerschlagbiegeversuch.) M. BEILHACK. *Forschung auf dem Gebiete des Ingenieurwesens,* No. 354, Section B, Vol. 3, May-June, 1932, pages 1-22. 7

The endurance impact-bending test is an impact test made on notched rods in which the material to be tested is stressed and examined not in the range of the plastic deformation as is the case in the notch-impact test; it can be called a dynamic fatigue test. The apparatus and machines for this test are described and results of tests of the dependence of number of impacts on weight and height of impact discussed. Oscillographic curves were taken to determine the vibrations occurring during an impact and formulas are developed for the numerical calculation of the diagram time-path for the elastic impact with and without losses. It is pointed out that in order to properly judge a material by this fatigue test not only the energy of the impact and the number of impacts leading to fracture, but also the weight and the height of the falling weight be given. The deflection during the test should also be given as from it the magnitude of the stresses in the sample can be approximately calculated. The individual tests are reproduced in full and illustrated by micrographs. 8 references. Ha (6f) 8

Nickel Tubing Resists Fatigue. R. WORTHINGTON. *Inco,* Vol. 11, No. 2, 1932, pages 11, 29.

Endurance Corrosion Tests on Condenser Tubes in Operation. (Dauerversuche über die Korrosionen von Kondensatorrohren im Betrieb.) P. REUTER. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Apr. 1932, page 109. 9

The corrosion tests comprised condenser tubes of 4 marine alloys, a 70% brass without Sn, a 98.5% Cu alloy (1.5 Sn), a 97% Cu-3% Al bronze, a 85% Cu-15% Ni alloy. Contrary to general experience it was found that all of the alloys with coarse grain were much more resistant against corrosion than the fine grained. GN (6f)

Cadmium Plating vs. Corrosion-fatigue, Pickling vs. Corrosion-fatigue. WILBER E. HARVEY. *Metals & Alloys,* Vol. 3, Mar. 1932, pages 69-72. 10

4 references. Fatigue values when the parts are exposed to corrosion by water are very greatly decreased and even the highest strength steels have values of less than 25,000 lbs./in.^{2} under such conditions. The experiments reported by the author show that Cd and Zn coatings are very effective in protecting against corrosion fatigue. H_2 absorbed in pickling operations preparatory to plating has a very deleterious effect upon the corrosion fatigue value of the plated material. Use of organic compounds in connection with the cleaning aids in avoiding the embrittlement due to H_2. WLC (6f)

Isn't it a relief, to ask a question and have the correct answer stare you in the face?

Slip a specimen . . . a machine part . . . or a die . . . into a ROCKWELL HARDNESS TESTER and in about the time it requires to take one puff of a cigarette you will have the correct, sure, hardness on the dial.

The Rockwell doesn't tell you it has done half the work and you are to peer into a microscope and *do all the measurement yourself.*

A couple of handles and *one* dial are all you need be concerned with . . . leave the rest to the Rockwell.

Endurance Strength of Screws. (Dauerfestigkeit von Schrauben.) W. STAEDEL. *Forschung (Zeitschrift Technische Mechanik und Thermodynamik)*, Vol. 3, Mar.-Apr. 1932, pages 106-108.

The endurance strength of screw connections in relation to the thread tolerance were made with a specially designed endurance machine. 6 references. GN (6f)

General Statements about Fatigue Fractures on Electrically driven Shafts. (Allgemeines über Schwingungsbrüche bei elektrischem Antrieb.) W. REINECKE. *Maschinenbau*, Vol. 11, July 7, 1932, pages 272-273.

One of a series of articles dealing with problems of fatigue fractures. Errors in fabrication, inspection and mounting are discussed. Mechanically and electrically driven shafts are compared. RFV (6f)

Endurance Tests with Riveted Joints. (Dauerversuche mit Nietverbindungen.) K. SCHAECHTERLE. *Stahlbau*, Supplement to *Bautechnik*, Vol. 10, Apr. 24, 1932, pages 65-72.

The static and dynamic properties of joints with 1, 2, 3 and 4 rows of rivets were tested. The maximum breaking loads in the endurance tests are up to 57% below the static breaking loads. The main results are given in the following table:

Type of joint	Maximum breaking load static tensile test kg./cm.²	Maximum breaking load endurance test kg./cm.²	Ratio endurance load to static breaking load
1 row	31,000	19,400	.63
2 rows	63,750	34,000	.53
3 rows	83,150	35,800	.43
4 rows	.....	39,100	..

Whereas in the static test of the 1-row rivet joint the rivet was sheared off; in the 2-row joint, the rivets were sheared off and the plates simultaneously torn. In the 3-row joint the plates were torn in the cross-sections of the outside rivet rows. In the fatigue tests all samples show the characteristic fatigue fracture. From the fatigue loads the normal and shear stresses in the rivets were determined. The 2-row joint shows a relatively high fatigue strength. The fatigue strength decreases rather continually with increasing pressure in the rivet hole. When the pressure in the wall of the rivet hole exceeds a certain limit the fatigue strength decreases suddenly. 3 references. GN (6f)

The Rivet Joint. New Knowledge From Endurance Tests. (Die Nietverbindung. Neue Erkenntnisse aus Dauerversuchen.) K. SCHAECHTERLE. *Bautechnik*, Vol. 10, May 20, 1932, pages 275-278; May 27, 1932, pages 290-294.

The first part of the paper is given to an analysis of the stresses in rivet joints. Yield point, tensile strength, elongation and reduction of area of the steel plate to be used in the joints, and the static and endurance properties of joints in a Schenck endurance testing machine were determined. The results of fatigue tests on low carbon steel plate are in accord with practical experiences. It is shown that the fatigue properties of steel plate as well as rivet are satisfactorily utilized in the common methods for calculating and dimensioning riveted joints. In riveted steel constructions calculated and dimensioned according to the German specifications (D I N 1073) the safety factor against fatigue failure amounts to about 1.4-1.5. For normal constructions the present method of calculation suffices. In special cases it is possible to increase the stresses endured close to the fatigue limit. In using steels with higher tensile strength and yield point it is possible by properly dimensioning and making the joint to fully utilize the fatigue limit as determined on the bored plate with rolling skin. The paper finally points out that in order to obtain reliable data on the calculation of riveted joints the common static tensile tests should be supplemented by fatigue tests. As a yardstick for the suitability of a certain structural steel (sensitivity to notch effects, effect of the surface condition, effect of the holes in the riveted construction) the fatigue limit as determined on standard flat bars of plates with rolling skin and provided with rivet holes should be used. 15 references. Vibration and Fatigue in Electrical Conductors. A. E. DAVISON, J. A. INGLES & V. M. MARTINOFF. *Electrical Engineering*, Vol. 51, June 1932, pages 412-413.

A discussion of vibration in electrical conductors leads the author to the necessity for the development of some new types of conductor which must have either some other shape or other inherent qualities in order to withstand better the tendency to vibrate and to fail because of resulting fatigue than the standard sections now used. Ha (6f)

Endurance Strength Tests with Welded Girders. (Dauerfestigkeitsversuche mit geschweissten Trägern.) R. HOCHHEIM. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns*, Vol. 1, Mar. 1932, pages 225-227.

2 girders welded together of flats in double-T shape with reinforcing ribs and the seams running throughout the length of the girder were subjected to an alternating load between 24,000 and 8,000 kg./mm.²; after 2,160,900 changes of load the girder was still fully intact. It could be stated that girders welded over the whole length (not in places only) are insensitive to static stresses even above the range of the elastic limit; this means that this manner of welding presents the best utilization of the material of composite sections. Ha (6f)

Endurance Tests with Welded Joints. (Dauerversuche mit Schweissverbindungen.) O. GRAF. *Bautechnik*, Vol. 10, July 22, 1932, pages 414-417.

The principal results of the investigation are: (1) Gas welded joints showed higher endurance strength than electrically welded joints. (2) Butt welded joints showed higher endurance strength than certain lap welded joints made according to German specifications. (3) The length of the lap weld has a considerable bearing on the endurance strength even when the fracture does not occur within the seam but at the beginning of the joint. (4) In the lap welded joints fracture always occurred in the beginning of the joint. (5) All of the results prove that proper design of the welded joint, selection of the welding rod and subsequent treatment of the joint afford increased attention, when joints are concerned that are subjected to alternating loads. GN (6f

ELECTRO-CHEMISTRY (7)

Electrometallurgy. (Allgemeine und technische Elektrometallurgie.) ROBERT MÜLLER. Julius Springer, Vienna, 1932. Cloth, 6¼x9¼ inches, 580 pages. Price 32.50 RM.

1 The chemistry and electrochemistry of the deposition of the metallic elements, from aqueous solutions or from fused salts, as the case may be, are thoroughly discussed in this comprehensive text book. Electrolytic refining and electroplating are described as special cases in connection with each element, the conditions used being led up to after discussion of its electrochemical behavior. Many current density-potential curves are given.

Some sketches of commercial cells are shown, but the volume deals more with principles than with commercial practice. Suitable plating baths are given, but it is far from a mere book of recipes.

2 Thousands of references to the literature are included, the selection being aimed at completeness. Many very old references are given including a good many references to patent literature, of doubtful value from the technical point of view. The book is well printed, well bound and well indexed. It deals only with electrolysis, not with electrothermics.

It is a valuable reference book. H. W. Gillett (7)-B-

The Handling of Cyanide Baths in Electroplating. (Über die Behandlung cyankalischer Bäder in der Galvanotechnik.) K. HÜTTENES. *Metallwaren Industrie und Galvanotechnik*, Vol. 29, Feb. 1, 1931, pages 55-56.

3 Discusses the removal of excess K_2CO_3 or Na_2CO_3 from cyanide baths by a freezing out process. Anodic slimes in brass baths are often caused by NH_4Cl which should be replaced by NH_4OH. EF (7)

Chrome Plating of Light Metals, in particular of Aluminum and Aluminum Alloys. (Verchromung von Leichtmetallen, besonders von Aluminium und Aluminiumlegierungen.) GEO. BUCHNER. *Oberflächentechnik*, Vol. 9, June 7, 1932, page 113.

5 While a thickness of 0.001 mm. Cr on Cu plated or Ni plated objects gives a very good protection against atmospheric influences, a thicker Cr layer hardens the surface in such a manner that the life of the article is greatly lengthened. This is especially true of dies. Only HCl has a harmful influence on Cr. For this reason, Cr plating is a good field for surface-hardening of light metals. It is very important to keep temperature and current density in proper limits. Articles of Al alloys can be Cr plated directly, without any intermediary layer. The methods of Cr plating are briefly described. Ha (7a)

Galvanic Protective Coats and their Application in the Wire and Cable Industry. (Galvanische Schutzüberzüge und ihre Anwendung in der Draht- und Kabelindustrie.) E. BERTL. *Elektrotechnische Zeitschrift*, Vol. 53, June 16, 1932, page 579.

A fully reliable protection against corrosion of wires is obtained electrolytically only from deposits of bivalent metal ions of Sn and Pb which alone guarantee a complete denseness and uniformity; baths containing bivalent and 4-valent ions or only 4-valent ions do not produce a properly adhering coating; it can be wiped off. A thickness of 0.009 mm. Pb suffices for corrosion protection if no mechanical stresses are present. In practice, 0.3 mm. is customary. This corresponds to 3.33 kg./m.² Wires with rubber insulation need only 0.1-0.15 mm. or 0.72-1.08 kg./m.² The electrolytic plating process is considered superior to the thermal processes. Ha (7a)

Some Aspects of Throwing Power, Its Quantitative Expression. S. FIELD. *Preprint, Electroplaters' & Depositors' Technical Society*, London, Jan. 1932, pages 83-90.

New expressions of positive and negative throwing power are suggested on the basis of measuring it at a fixed distance ratio of 2. For positive throwing power, T.P. = 100 (D.R. - M.R.); for negative throwing power, T.P. = $-100\left(D.R. - \frac{A}{A-C}\right)$; where D.R. = Distance ratio, M.R. = Metal ratio, A = Weight of deposit on near plate, and C = Weight of deposit on distant plate. Apparatus for measuring throwing power was proposed in which 2 sections of the cathode are placed on the same side of the anode, one twice as distant from the anode as the other. For baths having nearly constant cathode efficiency with respect to current density, a set of ammeters are used instead of weighing the cathode plates, thus making the throwing power measurement a matter of few seconds. The Action of Certain Organic Compounds during the Electrolytic Deposition of Zinc. (L'azione di alcune sostanze organiche nella deposizione elettrolitica dello zinco.) L. Cambi & G. Devoto. *Atti della Reale Accademia Nazionale dei Lincei*, Vol. 15, Jan. 3, 1932, pages 27-29.

By polarographic studies, it is shown that pyridine and its basic substituted derivatives increase the efficiency of Zn deposition from basic solutions to 80-90%, compared to the usual 70%. This is due to a reduction of the deposition potential of Zn and not to a reduction in H overvoltage, the reduction amounting to 0.1 v with 0.1 Molal $ZnSO_4$, and 0.25 v for a similar $NiSO_4$ solution. The action of pyridine and its derivatives is specific, as piperidine has no such action. In practice, 100 g. of pyridine are consumed per 1000 kg. of cathode product. Its use makes it unnecessary to remove traces of impurities, such as Ni or Co. AWC (7a)

Nickel-Chromium. (Nickelchrom.) H. Hornauer. *Emailletechnische Monatsblätter*, Apr. 1932, pages 27-28.

Easy rusting and scaling of Cr plated articles is due to a faulty base plating of Ni. The Ni plating must be free of pores, tightly sticking and poor in H. In degreasing the article before Ni plating and Cr plating only well tried degreasing baths should be used. For Fe and steel parts electrolytic Cu baths are most adaptable. In such baths the parts first receive a thin coating of Cu before subsequent plating. For subsequent Ni plating the use of the rapid Ni plating bath "Auto-Rapid" is suggested. In plating the bath is heated to about 35° to 40° C. GN (7a)

Some Chemical Aspects of the Electroplating Industry. E. E. Halls. *Chemical Age*, London, Vol. 26, Apr. 23, 1932, pages 372-373.

Factors having a considerable influence on electroplating are impurity of metal anodes, cleaning and degreasing of work, uniform contents of bath ingredients and uniformity of current density. VVK (7a)

Studies on Silver Baths and Means to avoid the Tarnishing of Silver. (Studien über Silberbäder und Massnahmen gegen das Anlaufen des Silbers.) Walter Obst. *Deutsche Goldschmiedezeitung*, Vol. 35, June 4, 1932, pages 229-231.

The paper especially refers to some methods used for avoiding the tarnishing of Ag electrodeposits. GN (7a)

Electrometallurgy (7b)

The Removal of Bismuth in Lead by Means of Calcium. (Die Entwismutisierung von Blei mittels Kalzium.) *Die Metallbörse*, Vol. 22, Apr. 9, 1932, pages 450-451.

1 The electrolysis of raw Pb only works economically if the Bi content does not drop below 1%. While low Bi contents are usually not objectionable in Pb alloys, Bi must be removed in Pb used for certain chemical purposes. (0.05% max.) Experiments of Kroll yielded that Bi can be concentrated in dross by adding alkalies or earth alkalies to the lead bullion. According to his American Patent, 0.2% Bi in raw lead is reduced to 0.05% by Ca, while the concentration in the dross is as high as 5%. However As, Sb, Ag and Cu are also practically completely extracted. The low Ca content remaining in the Pb bath is removed by a chloridizing treatment or by steam. Experiments along the same line by R. F. Cohn, Columbia University, and at the University of Michigan confirmed earlier results. With regard to the economy, about the same quantity of Ca is required for 0.1% Bi. The economy increases up to 0.5% Bi. Four paramount points on which the economy of the Ca extraction process is based are given in conclusion. EF (7b)

The Action of Cyanide on Gold. G. O. Ramsay. *Chemical Engineering & Mining Review*, Vol. 24, Apr. 5, 1932, pages 236-237.

3 Various chemical equations representing the reactions between Au and KCN are shown and the possibility of the formation of H determined by means of a potentiometer, calomel cell, and a Au electrode. A distinct rise in potential difference is noted, which is most marked in the first 4 minutes. Passage of O over the Au electrode after 36 minutes' immersion caused an immediate drop in potential from .892 to .630 v. "If the measure of solubility of Au may be determined by the difference between its present potential difference and some definite figure such as is with this cell, .950 v., then it can be seen that any depressant such as O would not be without value to the cyanide process." 4 **On the Effect of Colloids on Technical Zinc Electrolysis. (Ueber den Einfluss von Kolloiden auf die technische Zinkelektrolyse.)** P. Röntgen & F. Felchner. *Archiv für Erzbergbau, Metallhüttenwesen*, Vol. 2, Mar. 1932, pages 26-48; Fritz Felchner. *Doctor's thesis, Technical Hochschule Aachen*, Feb. 1930, 32 pages.

5 Report from the Institute for Non-Ferrous Metallurgy and Electrometallurgy at the Technische Hochschule Aachen. Systematic experiments were carried on to study the effect of gelatine and glue on the electric deposition of chemically pure Zn from electrolytes of $ZnSO_4 + H_2SO_4$, of current density, variable content of acid and temperature of the electrolyte. Gelatine and glue decrease the current yield. The voltage of the electrolyte increases with increasing amount of colloids in the electrolyte. The yield of Zn is increased by a thermal decay of the colloids whereas the voltage decreases. In order to test whether the decrease of the current yield, as effected by the colloids added, is due to an increased solubility of the deposited Zn, comparative solubility tests were carried on on Zn cathodes which had been made from electrolytes with and without the addition of colloids. These tests resulted in a decrease of the corrosion for the Zn cathodes made from electrolytes with additions of colloids. With increasing electrolyzing temperature the yields are largest at low acid contents, they decrease with increasing content of gelatine, most at low temperatures. With increasing temperatures of the electrolyte the voltages show the largest differences at higher current densities. The differences are current consumption for various contents of acid and gelatine of the electrolyte are largest at low temperatures and gradually decrease with increasing temperature. A theoretical explanation of the occurrences at the electrolysis of $ZnSO_4 + H_2SO_4$ is obtained from the course of the current density-potential curves. The results of the investigation are plotted in numerous diagrams. 50 references. GN+Ha (7b)

Beryllium. Alfred Stock. *Preprint, The Electrochemical Society*, Vol. 61, Apr. 1932, pages 451-468.

8 The difficulty of obtaining Be by electrolysis in a fused electrolyte is due to the very marked affinity of the metal for O and C and to its high melting point (1300° C.). The author used a mixture of equal amounts of beryllium oxyfluoride and barium fluoride, operating the bath at 1400° C. Molten Be separates out at the water-cooled steel cathode. The extraction of Be from beryl is briefly described. For the quantitative estimation of Be in its ores, salts and finished products, a new analytical method was developed based on titration with chinalizarin. The properties and uses of Be are discussed. A particularly important field of application is the Be bronzes. LCP (7b)

The Production of Seamless Tubes from Materials of High Melting Points. (Die Herstellung von nahtlosen Röhren aus hochschmelzenden Stoffen.) J. A. M. van Liempt. *Metallwirtschaft*, Vol. 11, June 24, 1932, pages 357-359.

9 15 references. The method consists of depositing the metal by electro-chemical means or by thermal decomposition on a core and then dissolving the core away chemically. By this means small seamless tubes can be made from W, Mo, C, Pt metals, Ti, Zr, Hf and others. As an example W can be deposited from WCl_6 vapor at 2000° C. on a Mo core. The rate of deposition is from 5 to 25 mu/min. and there is practically no diffusion between the two metals. The Mo core is then dissolved in 85% conc. HNO_3 15% conc. H_2SO_4 at 90°C. The sp. gr. of the W tubes is about 19.22 and the tubes are vacuum tight. Tubes from 1 mm. dia., 3 cm. length, .1 mm. wall thickness to 12 mm. dia., 35 cm. length and 1 mm. wall thickness can be made. A single crystal W tube can be made by depositing on a single crystal Mo core. Very thin tubes can be made by depositing from a WCl_6 and H_2 mixture on a Cu core and melting out the Cu core. The tubes can also be drawn to a smaller size before removing the Mo core. CEM (7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Oxide Coatings on Aluminum. J. D. Edwards, M. Tosterud & H. K. Work. *Electrical Engineering,* Vol. 51, June 1932, page 406.

The characteristics of oxide films on Al are discussed and the large number of uses to which they have been practically applied are pointed out. The electrolytic rectifier and electrolytic condenser are among the most important utilizations. The oxide film is impermeable and has a high protective power. Its thickness can now be made comparable to that of a paint film. By a recently developed process they can be given a hardness like carborundum and of high dielectric strength for electrical insulation. Thick oxide films can also be colored by absorption of dyes or mineral pigments. Ha (8)

A Glance at Some Galvanizing Problems. Heinz Bablik. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 81-82.

The advantages and disadvantages of electro-galvanizing as compared to hot galvanizing are discussed. The practice of hot galvanizing as used in Central Europe is described. Good bending qualities are obtained by preventing the formation of Fe-Zn compounds in the coating which is accomplished by dipping the pickled and washed sheet in dilute Zn chloride solution, preheating the sheet to remove H, and adding Al to the Zn bath. Rhodium-finish. An American Method for the Improvement of White Gold. (Rhodium-finish. Eine neue amerikanische Weissgold-Veredelung.) G. Nikolaus. *Deutsche Goldschmiedezeitung,* Vol. 35, Jan. 16, 1932, page 26.

After a brief discussion of the points to be observed in melting white Au, mention is made of a new Rh coating method on white Au articles to be used instead of the former Cr finish. GN (8)

Some Reactions Occurring in "Hot-Dipping" Process. Edward J. Daniels. *Institute of Metals, Advance Copy* No. 610, Sept. 1932, 14 pages.

Quantitative study of the reactions between steel, flux and molted Zn proved that the dross in the Zn bath resulted from reactions between the bath and the flux rather than between the steel and the bath. The part played by the flux in any hot-coating operation is discussed. In coating steel with Cd or Pb, the compounds $FeCd_2$ and $FePb_2$ are formed and insulate the steel from further attack by the melt. These compounds are both magnetic and rise to the top of the bath. The action of molten Sn on an 8% Al bronze results in the formation on the bronze surface of the compound Cu_3Sn dissolving Sn and Al, which is only partly wetted by the Sn. 15 references. JLG (8)

The Tinning of Gray and Malleable Iron Castings. (Das Verzinnen von Grau- und Tempergusstellen.) E. Becker. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 1, 1932, pages 174-177.

The article describes the various methods of tinning which can be used in tinning castings of either gray cast iron or malleable cast iron. The various methods are outlined in detail and many practical hints are given to avoid failures. Hot tinning and electro-tinning gave the best coatings. GN (8)

Hard Facing in the Steel Industry. W. A. Moore. *Iron & Steel of Canada,* Vol. 15, Apr. 1932, pages 42-43; *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 265-266.

See *Metals & Alloys,* Vol. 3, Sept. 1932, page MA 271. OWE+MS (8)

Corrosion Resistant Coatings on Steel Castings. (Korrosions Beständige Ueberzüge auf Stahlgussstücken.) Karl Roesch. *Stahl und Eisen,* Vol. 52, May 19, 1932, pages 493-494.

Method studied by E. Knipp consisted of mixing finely divided alloys with a binder, either 2 to 3% clay or water glass and pouring on a steel casting. Although this appears simple, it is a difficult matter to get good thick coats to stay welded onto the surface of a casting. A strong borax solution is used as a flux. Pure Ni and ferro-silicon do not weld on, while powdered Ni acts as a favorable addition agent to other alloys in making thick coatings. Altogether 14 pulverized mixtures were examined and all data is compiled in the table.

Knipp made some reminders for this type of coating work: (1) the coating should not be porous; addition of Ni gives better results; (2) a definite ratio should exist between thickness of casting and thickness of coating; (3) the casting should be poured in at the bottom of sand mold; the stream of metal does not have to be vertical to the mold wall; (4) the mold should be poured uniformly.

Testing the Zinc Coating on Galvanized Wires. Geoffrey K. Rylands. *Engineer,* Vol. 153, Apr. 22, 1932, page 445.

Author is chairman of the committee of the British Standards Institution responsible for issuing Specification No. 443 bearing the above title. He defends the retaining of the Cu sulphate dipping test which is known to be not entirely satisfactory. Definite rules were laid down for performing the test which should aid in giving accurate results. LFM (8)

Metal Spraying—the Process and Devices and the Influence upon Welding of Some Recent Developments. H. B. Rice. *Journal American Welding Society,* Vol. 11, Sept. 1932, pages 26-30.

Paper presented at the Fall Meeting of the American Welding Society in Buffalo, Oct. 6, 1932. A description of the apparatus, some applications and costs of metal spraying. Greatest field for this process is the building up of worn machine parts and application of various metallic films to protect surface from corrosion. TEJ (8)

Experiments with Town Gas in a Modern Tin-plate Works. W. Clark Johnson. *Gas World,* Vol. 96, May 21, 1932, Industrial Gas Supplement, pages 11-15.

Paper presented before South Wales Branch of the Institution of Mechanical Engineers, Swansea, Apr. 12, 1932. The author considers the problem in the following order: the disadvantages of fuel oil; the essential features of tin-pot firing; early experiments with tin-pot firing; some of the results obtained; standard equipment required; the removal of waste gases; the annealing process; the cost of normalizing process; a model all-gas tinplate works. The discussion following the paper covered the questions on variation in temperature and reducing atmospheres. MAB (8)

Hard-Facing in Machine Manufacture. J. C. Huston. *Machinery,* Vol. 38, Mar. 1932, pages 513-514.

Gives many applications of hard facing in machine work. Discusses advantages and economies. Does not deal with methods of hard facing. RHP (8)

The Effect of Water Soaking Steel Upon the Weight of Zinc Deposited. Wallace G. Imhoff. *Brass World,* Vol. 28, July 1932, pages 142-143.

Water soaking was accidentally found to yield a heavier, but poorer, grade of deposit when galvanizing. The deposit is harder and more brittle. WHB (8)

A New Metallizing Process. (Ein neues Metallisierungsverfahren.) A. Karsten. *Oberflächentechnik,* Vol. 9, May 24, 1932, pages 100-101.

The process consists in rubbing-on or spraying-on of a metal on an intermediary layer between object and metallic layer. The intermediary layer is made up of a mixture of a powder with water which after drying forms a very resistant, fire-proof coating insoluble in water. The method can be applied for interior decorating; art-objects, brickwork, wood, etc.; rubbing-on gives only thin layers, while thicker metallic layers must be sprayed on. Color effects can easily be obtained by suitable additions. Ha (8)

Lead Coating with the Oxy-Acetylene Flame. (Das Verbleien mit der Sauerstoff-Acetylenflamme.) H. Kalpers. *Gas und Wasserfach,* Vol. 75, July 23, 1932, page 614.

Pb coating with the oxy-acetylene flame seems to be successful. Several practical examples are discussed. In Pb coating steel plates an intermediate layer of a 50% Pb-50% Zn alloy is suitably used which guarantees good adhesion. Advantages are high chemical resistance of Pb in combination with high mechanical strength of base metal. GN (8)

A New Heat Application for Galvanizing. W. H. Spowers. *Wire & Wire Products,* Vol. 7, July 1932, pages 226-227, 236-237.

The gas is made to burn with a "diffusion flame" in this process, that is with an intensely luminous flame which is obtained by letting the combustion air reach the gas by diffusion through the flame proper which thus becomes an intense source of radiant energy of relatively low temperature but high emissivity. The application of such flame to hot galvanizing by impact burners to a heat radiating refractory bed installed between flame and side of kettle is described; the advantage consists especially in reducing the dross considerably, sometimes up to 35% and corresponding addition to pot life. Ha (8)

Aluminum-coated Iron and its Use. (Aluminiumplattiertes Eisen und seine Verwendung.) *Aluminium,* Vol. 14, Apr. 30, 1932, pages 3-4.

Soft Fe with Al rolled on is recommended for many industrial purposes. Ha (8)

Wire Galvanizing Processes. L. D. Whitehead. *Wire & Wire Products,* Vol. 7, May 1932, pages 148-151, 166-169.

This instalment concludes a discussion on hot-galvanizing vs. electro-galvanizing in which various authors have contributed their views in favor of the one or the other process. Here the methods of the electric process as carried out by the Crapo process are defended against hot-galvanizing. An editorial comment reviews briefly the discussions, no decision was made as to which is the better process. Ha (8)

DTR (8)

INDUSTRIAL USES & APPLICATIONS (9)

Nickel-Chromium Steel Spades and Shovels. *Nickel Bulletin,* Vol. 5, Apr. 1932, pages 81-82.

The steel for these implements is of the following composition: C 0.41, Si 0.35, Mn 0.63, S 0.025, P 0.023, Ni 1.28, Cr 0.80. They are forged at 900°-950° C. and annealed at the same temperature. The process of manufacture is described fully. Ha (9)

Nickel and Its Alloys in the Chemical Industry. (Les applications du nickel et de ses alliages dans l'industrie chimique.) *Revue du Nickel,* Vol. 3, Jan. 1932, pages 2-15.

General discussion. AH (9)

The Iron Road, a New Export Outlet for Iron Foundries? (Die "Eiserne Strasse," ein neues Absatzgebiet für Eisengiessereien?) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 26, 1932, pages 253-254.

Description of the cast iron road pavement, system Schmid. GN (9)

The Manufacture of Gears. *Nickel Bulletin,* Vol. 5, Apr. 1932, pages 73-80.

The plant, laboratory and working methods of the products of David Brown & Sons, England, are described and illustrated. For turbine gears where circumferential speeds up to 15,000 ft./min. are used, a Ni-Cr-Mo steel of the following composition and properties is used: C 0.28-0.32, Si 0.3, S 0.04, P 0.04, Mn 0.5-0.8, Ni 3-3.75, Cr 0.5-1.0, Mo 0.25-0.40; yield point 40 tons/in.^{2}, maximum stress 55-60 tons/^{2}, elongation 18%, reduction of area 50%, Izod impact value 40 ft. lbs. Ha (9)

Interesting Uses of Sheet Lead. *Sheet Metal Worker,* Vol. 23, June 1932, page 295.

The application of sheet Pb flashings to waterproof sidewalks, shower stalls or bathrooms, and chimney flashings is illustrated by sketches showing details of construction. Ha (

A Drilling Machine Made of Welded Steel Tubes. (Aus Stahlrohr hergestellte geschweisste Säulenbohrmaschine.) *Die Röhrenindustrie,* Vol. 24, July 30, 1931, page 185.

Some view points regarding the welded frame of drilling machines are set forth. EF (9)

Large Uses of Steel in Small Ways. 211th Article. Oil Burners. *Steel,* Vol. 90, Feb. 22, 1932, pages 28-30.

Domestic oil burners are being installed in the U. S. at the rate of 126,000 a year and commercial oil burners in offices, hotels and apartment houses at the rate of 3000 a year. There are only 20 lbs. of steel and 60 lbs. of cast Fe used in the average oil burner unit but the manufacture of storage tanks and piping raises the total steel consumption by the oil burner industry to 48,000 tons per year. JN (9)

Large Uses of Steel in Small Ways. 212th Article. Woven Wire Fencing. *Steel,* Vol. 90, Mar. 7, 1932, page 38.

Over 50,000 tons of steel are used annually in the production of woven wire fencing. The major portion of this is used on the farm. Other large uses are for enclosing industrial plants, parks, playgrounds, cemeteries, estates, airports and golf courses. JN (9)

Large Uses of Steel in Small Ways. 213th Article. Bullet Cores. *Steel,* Vol. 90, Mar. 21, 1932, pages 38, 40.

Since 1924, the U. S. Government has used on an average 55,860 lbs. of W-Cr steel and 100,000 lbs. of mild C steel annually in the manufacture of caliber .30 and caliber .50 bullet cores. Orders on hand call for the use of 178,300 lbs. of alloy steel and 444,600 lbs. of mild C steel for this purpose. JN (9)

Large Uses of Steel in Small Ways. 214th Article. Miniature Trains. *Steel,* Vol. 90, Apr. 4, 1932, page 48.

The production of miniature trains and equipment consumes 5,300 tons of steel annually. Only 25% of the output are wind-up units, the remainder being narrow and widegage electric trains. About 80% of the metal used is steel. The types of steel making up the various parts of these train sets are outlined and a short account is given of their manufacture. JN (9)

Chrome-Nickel Steel Trim has Concrete Backing. *Steel,* Vol. 90, Apr. 4, 1932, pages 38, 40.

A new use for corrosion-resisting steel as an exterior finish for buildings is shown in the construction of 2 new store buildings. Steel sheets are bent into the required shape and then backed intimately with a 4-5" layer of lightweight concrete. These metal and concrete units are set into the wall in the same manner as cut stone by means of a 3/16" mortar joint. Advantages of this method of construction are decreased danger of denting the steel by impact, greater resistance to twisting or warping of the metal, and the elimination of the possibility of moisture condensing on the inside of the steel sheet. JN (9)

Reducing Haulage Costs Through Proper Application of Bearings. S. M. Weckstein. *Mining Congress Journal,* Vol. 18, June 1932, page 14.

Anti-friction and tapered roller bearings play a major part in economical coal mining transportation. The following definite advantages are summed up: (1) Increased tonnage of coal handled per train by 60%, (2) Reduced car lubrication costs 79%, (3) Reduced car maintenance costs 75%, (4) Reduced track maintenance (due to wrecks) practically 100%, (5) Reduced power consumption per ton of coal hauled. DTR (9)

Preheaters Made of Alloy Steel. (Wärmeaustaucher aus Edelstahl.) Kurt Rummel. *Stahl und Eisen,* Vol. 52, June 9, 1932, pages 559-562.

Report 163 of Heat Section of Verein deutscher Eisenhüttenleute. The use of high grade or heat-resistant steel as a substitute for ordinary Fe preheaters opens up a new field. Preheating with heat-resistant steel may give temperatures up to 900° C. without any danger and afford a means of making large savings in fuel. For rolling mill, forging, and annealing furnaces, it was possible to cut fuel costs 20 to 30%, together with considerable increase in production. This data was actually derived from recuperators built of refined steel parts and operated in various mills by the Düsseldorf Heat Section. Illustrations of the various types of preheater construction are shown. DTR (9)

Aluminum Alloy Mine Skips and Cages. *Canadian Mining Journal,* Vol. 52, Aug. 1932, pages 362-363.

Several mine skips and cages have been built in Canada for Kirkland lake mines. Advantages of these are: lightness, and strength (with correct designing). WHB (9)

1 **Duralumin Mine Skips.** *Canadian Mining Journal,* Vol. 53, July 1932, page 297.

The skip body is constructed of duralumin plates and angles riveted together by means of duralumin rivets. Rollers and fillings are frequently made from duralumin forgings. To resist abrasive action of the ore and rock, skips are lined, as to their sides, with Mn- or bulletproof steel plates, and as to their bottoms with Mn steel plates or Luratex rubber liners. Duralumin skips are compared with steel skips. WHB (9)

2 **Comparison of Different Heat Insulators in Electric Cooking and Baking Tubes with Particular Reference to Aluminum Foil. (Vergleich verschiedener Wärmeisoliermittel bei elektrischen Brat- und Backröhren unter besonderer Berücksichtigung der Aluminiumfolie.)** *Elektrizitätswirtschaft,* Vol. 31, Mar. 31, 1932, page 150.

The heat insulation effect of kieselguhr, slag and glass wool is based on the great number of pores filled with air. The insulation space can also be effectively subdivided by metallic walls. The low radiation coefficient is of paramount importance which must also be maintained after oxidation. The following table compares the radiation coefficients of 3 metals:

3

Metal:	Polished State:	Oxidized:
Al	0.26	0.35
Cu	0.19	3.86
Fe	0.29	3.40

Tests in the Technische Hochschule Hanover confirmed the superior insulation properties of Al-foils, which are also distinguished by their low heat capacity, thus reducing the heating times. EF (9)

Rational Use of Copper and Brass in Heating Installations for Heavy Oils. (L'Emploi rationnel du cuivre dans les installations aux huiles lourdes.) *Cuivre et Laiton,* Vol. 5, June 30, 1932, pages 273-282.

4 General advantages and details of pipe line construction are described and illustrated. Ha (9)

Aluminum-Silicon Alloys as Piston Materials. *Engineering,* Vol. 133, Feb. 5, 1932, pages 172-173.

Outlines the various properties of Al-Si alloys which make them suitable for pistons. By proper heat treatment the Brinell hardness of Y-alloy can be increased from 80 to 125. The high thermal conductivity, the low density which is the lowest of all commercial Al alloys, and the very low coefficient of linear expansion of these high-silicon Al alloys are excellent properties for piston materials. LFM (9)

5 **Hoover Dam Penstocks Set Record for Size.** *Engineering News-Record,* Vol. 109, July 21, 1932, pages 79-80.

Penstock, control and discharge equipment involves the fabrication of 4,600 ft. of plate steel pipe 30 ft. in diameter; 1,900 ft. of 25 ft. pipe; 2,550 ft. of 13 ft. and 1,860 ft. of 8½ ft. pipe. CBJ (9)

Houses of Copper and the Building Crisis. (Les Maisons en Cuivre et la Crise de la Construction.) *Cuivre et Laiton,* Vol. 5, May 15, 1932, page 210.

6 The possibilities of an extended use of Cu in building construction for economical reasons are discussed on the basis of examples shown in the Building Exhibition in Berlin and compared with the construction of ferrous materials. Ha (9)

New Welded Truss Design Uses Continuous Tension Members. *Engineering News-Record,* Vol. 109, Aug. 4, 1932, page 136.

Details of design for welded roof trusses to be used in new welded buildings of the Westinghouse Electric & Mfg. Co. at Derry, Pa. and Mansfield, Ohio. CBJ (9)

The Molding and Casting of Architectural Decorations. *Inco,* Vol. 11, No. 2, 1932, pages 18-21.

7 About 6 tons of art castings in Monel metal are used in decorating the new Federal Reserve Bank Building in Pittsburgh, Pa.; the molds, castings and finished ornaments are illustrated. Ha (9)

Resistance of Nickel to Hot Alkali. *Inco,* Vol. 11, No. 2, 1932, page 13.

The diaphragms in the electrolyzers for the production of hydrogen have been successfully replaced by Ni where formerly asbestos was used. The holes in the diaphragms are less than 0.004" in diameter, some 5000 to 6000 holes/in.^{2} Ha (9)

The World's Largest Klönne Holder. *Gas Journal,* Vol. 198, May 25, 1932, page 440.

8 The new 6 million cubic foot Stacey-Klönne holder at Syracuse, New York, has just been completed for the Syracuse Lighting Company. It is the largest of its kind and the first to be used on this side of the world. Discusses the materials used and the construction of the gas holder. MAB (9)

The Grocery Store Goes Metal. *Metalcraft,* Vol. 8, Apr. 1932, pages 150-151.

Ni and Monel metal have been used for counters, display cases, etc. throughout the store of the G. M. McKelvey Company Department Store of Youngstown, Ohio. VVK (9)

Test House Will Demonstrate Practicability of Enameled Steel Sheets in Residence Construction. *Metalcraft,* Vol. 8, May 1932, pages 202-203.

9 A steel house faced with porcelain enamel is now being constructed at Cleveland. VVK (9)

Tantalum Used as a Binder for Tungsten Carbide. *Machinery,* Vol. 38, Mar. 1932, page 488.

The Firth-Sterling Steel Co. has experimented with tungsten carbide particles bound by an alloy containing Ta, W, C and Co. This appears to have some advantages over the older plain tungsten carbide or over tantalum carbide. RHP (9)

Frameless Steel House Will Cost Less Than Ordinary Frame Dwelling. *Metalcraft,* Vol. 8, Mar. 1932, pages 135-136.

10 A detailed account of the all-steel house announced by the Insulated Steel Floor & Wall Co. of Cleveland. VVK (9)

Ornamental Leadwork Has an Interesting Background of Tradition. R. L. Zeigfeld. *Metalcraft,* Vol. 8, May 1932, pages 184-189. Many applications of lead for ornamental and practical purposes are described. VVK (9)

Welded Constructions in a Large Mine. (Geschweisste Konstruktionen bei den Übertagebauten einer Grosschachtanlage.) ZOEPKE. *Der Bauingenieur,* Vol. 13, May 20, 1932, pages 297-302.

Detailed description of the welded construction of the German mine Zollverein, Essen-Katenberg. All parts of the coal washing plant and the coal conveyor system which have been welded are described. 2000 tons of steel have been welded in all in the above buildings. All constructions in sheet are welded; a saving in weight of 15% could thus be effected. These are the largest welded constructions in Europe. GN (9)

Smart Apartment Hotel Demonstrates Harmonious Use of Metal. *Metalcraft,* Vol. 8, May 1932, pages 178-181.

The use of metal such as Al for porte cochere, entrances, lobbies, etc., in apartment houses is illustrated in the Kennedy Warren Apartment Hotel, Washington, D. C. VVK (9)

Copenhagen's Copper Clad Building. *Metalcraft,* Vol. 8, Apr. 1932, page 152.

The 7 story Vesterport building in Copenhagen is entirely surfaced both sides and roof with Cu. 240,000 lbs. were used and it is expected, in that atmosphere, that the metal will weather with a bluish tint. VVK (9)

The Development of Steel Constructions in the Mining Industry. (Die Entwicklung der Stahlbauten im Bergbau.) R. WÜRKER. *Kohle und Erz,* Vol. 29, Mar. 1, 1932, pages 74-79; Apr. 1, 1932, pages 99-103; May 1, 1932, pages 138-139.

A detailed illustrated description of steel constructions in German mines built in the last decade. 12 references. GN (9)

Monel Metal Bolts. R. WORTHINGTON. *Bulletin T-1, International Nickel Company,* pages 2-8.

The properties of Monel metal bolts are laid down in curves and tables; their ductility in combination with highest strength make them particularly useful in the case of corrosion exposure. Examples of application on the keel of ships, under-water structures, outdoor power stations are illustrated. Ha (9)

Lead Roofs for Beautiful Appearance and Freedom From Maintenance Costs. R. L. ZEIGFELD. *Metalcraft,* Vol. 8, Apr. 1932, pages 164-167.

A description of old and new lead roofs with directions for using the metal for that purpose. VVK (9)

Long Continuous Girders at Cincinnati Terminal. TRUMAN P. YOUNG. *Engineering News-Record,* Vol. 109, July 28, 1932, pages 110-112.

146-ft., 45 ton girders were erected for the approach to Union passenger tracks. Details of girder design and construction are discussed. CBJ (9)

Metallurgy in the Railroad Field. A. E. WHITE. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Railroads, pages 11-14.

The foremost points of consideration in locomotive practice is safety first; any change in the materials used must therefore be subject to close scrutiny from this viewpoint. It is pointed out that in order to improve a given part changes in design should be considered which would minimize the chances for defects due to improper or improperly controlled manufacturing practice. The requirements on some materials used in locomotives are tabulated. Ha (9)

Light Metal Doors for Rapid Transit Cars. (Leichtmetalltüren für Schnellbahnwagen.) G. WAGNER. *Glasers Annalen,* Vol. 111, July 1932, pages 1-9.

The paper reports the practical experience of the German Federal Railway with cast Silumin doors and with riveted Lautal sheet doors. The latter type is the most appropriate and economic type developed in Germany. With a lower weight they are more stable and cheaper than any other construction. They are by 17.3% lighter than cast Silumin doors and by 7.5% lighter than the former Teakwood doors. GN (9)

Sheet Metal Airplane Construction. HERBERT WAGNER. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Aeronautical Section, pages 151-161.

Theoretical considerations of bracing and sheet metal covering of light metals, especially duralumin are analyzed with respect to arrangement, shaping and supporting and illustrated by many examples of constructions of German metal planes. Ha (9)

Wall Fillings of Aluminum. (Wandfüllungen aus Aluminium.) WERNEKKE. *Aluminium,* Vol. 14, Apr. 30, 1932, pages 1-2.

Al alloys with 1.25 Mn cast in sand molds are used for decorative purposes; color effects can be obtained by electrolytic treatment of the Al. The American practice in using such plates is mentioned. Ha (9)

Use of Chromium Plating for Decorative Purposes. HENRY WEITZ. *Metalcraft,* Vol. 8, June 1932, page 244.

A general article. VVK (9)

Nickel as a Catalyst in Chemical Reactions. (Le nickel catalyseur de reactions chimiques.) PAUL SABATIER. *Revue du Nickel,* Vol. 3, Jan. 1932, pages 18-20.

Ni is an excellent catalyst for hydrogenation reactions. It is therefore used in industry for hydrogenation of hydrocarbons, compounds of the aromatic series, benzene, carbides, phenols, amines, ethers, organic oxides, carbon oxides into methane, oils into solid greases. In order to be used as a catalyst, Ni must have been reduced from its oxides and must be in finely divided form. AH (9)

Three Important Principles for the Calculation of Ropes. (Drei wichtige Grundgedanken zur praktischen Seilberechnung.) F. SKROBANEK. *Zeitschrift des Österreichischen Ingenieur-und Architektenvereins,* Vol. 84, Feb. 12, 1932, pages 21-23.

The paper considers the effects on the deflection of strained ropes and wires of wind pressure, rigidity and temperature. GN (9)

Shipbuilding and Its Relation to the Steel Industry. H. GERRISH SMITH. *Year Book of the American Iron & Steel Institute,* 1931, pages 80-105.

1 **Characteristics of Piston Material, with Special Reference to Wear Resistance. (Characteristik von Kolbenmaterialien unter besonderer Berücksichtigung des Verschleisswerts.)** E. W. KOCH. Doctor's thesis, 1931, Technische Hochschule Aachen. Paper, 8¼ x 11 inches, 47 pages. Mimeographed.

Failures of pistons in automotive engines through brittleness, fusion, thermal distortion, wear, etc. are discussed and illustrated. Piston operating temperatures and the temperature gradient through the piston are tabulated. In air-cooled airplane motors the center of a cast iron piston head may reach 240°-290° C. with Mg base alloys, 265°-280° C. with

2 Al base alloys and 325°-450° C. with gray iron.

Factors in the usefulness of a piston are uniformity, specific gravity, thermal expansion, thermal conductivity, strength, ductility, hardness and wear resistance. In the last 4, the values at operating temperatures are important.

Data on these properties are recorded for some 40 materials used or suggested for pistons. A huge mass of data on wear resistance is presented. The wear tests were made in oil heated to 95°-100° C., on flat surfaces of 1 cm.² area, held tangentially under a pressure of 8 kg. against rotating disks of cast iron 12 cm. diameter, at 1400 r.p.m. The width of the worn area on the specimen was taken as a measure

3 of wear. The cast iron disks (or rather tires) were cut from automobile cylinders of unalloyed cast iron of 184 Brinell, and the specimens themselves from actual pistons. A comparison specimen from a heat-treated Nelson Bohnalite piston of 10% Cu, 1% Fe, 0.3% Mg with 145 Brinell was run in each test as a standard material. Various finishes were used on disks and samples, and in some cases the oil was diluted and in others abrasive was added to the oil. One apparatus carried the Bohnalite standard and one other sample, another carried the standard and 9 other samples, each with its own lever arm and loading weight.

4 It is not clear whether the cast iron surface was refinished before each test. The time of running varied from a few minutes to 300 hours. The width of the worn area is plotted in curves, and the ratio between that width on Bohnalite and on the other test specimens run simultaneously with it is tabulated and used as a wear index. The roughness of the cast iron surface was the largest factor in the rate of wear. Wear appeared to be controlled rather more by composition than by slight changes in hardness or heat-treatment. Under comparable conditions against gray iron, nitrided steel showed 1/5, hard steel 1/4, and other gray irons 1/3 to 2/3

5 the wear (width of worn area) as Bohnalite. Various Al Si alloys showed 0.6 to 0.9, various Al Mg alloys about the same, other alloys of the Al Cu class about the same, Y alloy 0.8 to 0.9 and the Mg base alloys 1.2 to 1.7. With diluted oil (2/3 benzine) the Mg base alloys showed much higher relative wear while the other light alloys did not greatly alter their positions relative to Bohnalite.

Koch tabulates the standings of the various alloys as to specific gravity, coefficient of expansion, thermal conductivity, wear resistance, high temperature strength (average of Brinells at 100°, 200° and 300° C.) and the room temperature elongation, gives each property a weighting factor ac-

6 cording to the use the piston is to be put to, and adds the weighted values together to give a merit index for that use. For instance for a piston for use in a racing motor, specific gravity is multiplied by 3 and wear resistance and expansion omitted entirely, while for a slow speed Diesel, specific gravity has a weight of 1, wear resistance of 2. The 15 tables of merit indices cover the range from airplane engines to ammonia machines.

The merit index for ordinary automobile pistons puts the materials standing at the head of the list in the following order, Bohnalite, cast iron, a 20% Si complex Al Si alloy;

7 for sport automobiles, Y alloy, Duralumin (forged), Bohnalite; for trucks, Bohnalite, Y, Titanal (an alloy similar to Bohnalite plus some 4% Si), cast iron, Al Si alloy; for busses, Bohnalite, cast iron, Y.

The 8 to 18% Mg alloys of Al are not included in this tabulation since only those alloys in commercial use are considered, but Koch thinks such alloys deserve much attention. H. W. Gillett (9)-B-

Improvements in Steels for Wood-Cutting Saws and Knives. HENRY B. ALLEN. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Wood Industries, pages 43-47.

8 It has so far not been possible to obtain a steel which would be satisfactory for both blade and cutting-edge of a saw for wood-cutting; the edge-holding properties will require a separation of edge and blade just as has been done in metal cutting. The difficulties of doing this and some typical steel compositions for saws and energy requirements for cutting different kinds of wood are given. See also "Improvement in Saw Steels Attributed to Alloys," *Metals & Alloys,* Vol. 2, Aug. 1931, page 153. Ha (9)

Steels for Modern Locomotive Construction. W. B. PICKERING. *Railway Engineer,* Vol. 52, Dec. 1931, pages 483-484.

Arc-Welded Jigs, Fixtures and Machine Tools. J. R. WEAVER. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 33-39.

10 The advantages of welded jigs and fixtures are pointed out and illustrated by many examples. Foremost among them over those of cast construction are production on short notice, strength combined with lightness and ease of alteration. See also *Metals & Alloys,* Vol. 1, July 1930, page 631. Ha (9)

HEAT TREATMENT (10)

Hardening and Tempering Razor Blades. E. C. Cook. *Heat Treating & Forging,* Vol. 18, May 1932, pages 303-305.

Strip is heated in tube furnaces, consisting of a cylindrical refractory lining encased in a steel-plate shell with gas burners located from the top on one side and from the bottom on the opposite side. The flame surrounds and heats an oval tube of heat resisting alloy, through which the strip passes. Furnaces are usually 9-12 ft. long, with a capacity of 7500-10,000 blades/hr. Gas atmosphere is maintained in the tube. Upon leaving the furnace, the strip passes between water-cooled dies, the upper die being counterbalanced. Blades are tempered preferably in strip form, small furnaces or dies being used. One manufacturer heats oil in a separate unit and pumps it through the dies, which are made of Nitralloy. New type of blades having a long center slot necessitates center annealing of the strip. This is done by means of fish-tail burners which fire through a slot in suitable water-cooled dies, generally similar to those employed for quenching, except that the slot is in the center. MS (10)

The Essentials of Hardening Simple Tools and Parts. Fred T. Potter. *Modern Machine Shop,* Vol. 5, July 1932, pages 7-11.

The practical methods to be followed in the hardening and tempering of small high speed and C steel sections are outlined. Ha (10a)

Magnetic Hardening of Steel. (Magnetisches Härten von Stahl.) E. G. Herbert. *Maschinenbau,* Vol. 11, Feb. 18, 1932, page 80.

Hardness of steel was greatly increased by revolving it in a strong magnetic field. After some time, however, the gain in hardness was lost again. New experiments for the purpose of retaining the increase in hardness were successful. This was made possible by a second treatment of a similar kind which is applied after a certain length of time which is determined by the grade of hardness desired. The second treatment takes 3 minutes without any previous heating whereas the first takes place at about 200° C. This temperature varies a little acording to the quality of steel. Practical use was made with razors, spiral drills, etc. RFV (10a)

Blocks Provide Neutral Atmosphere for Hardening. *Steel,* Vol. 90, Feb. 29, 1932, page 26.

A short description of the hollow, rectangular-shaped blocks made by the Sentry Co. of Taunton, Mass., for hardening high-speed tool steel. These blocks are molded of a carbonaceous mixture which generates gases and provides a neutral atmosphere which prevents scaling, decarburization and carburization of the steel placed inside the block. Case Hardening & Nitrogen Hardening (10c)

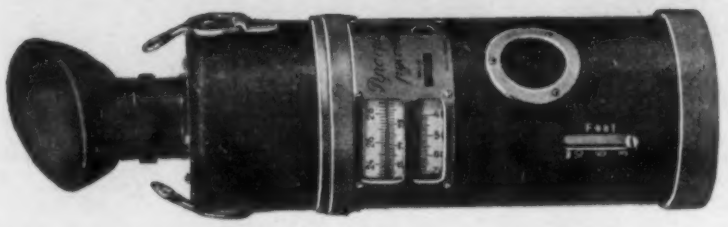
Make Your Own Carburizing Compound. *Iron & Steel of Canada,* Vol. 15, July 1932, page 84.



A brief article on a method adopted by a manufacturer for the preparation of carburizing compounds containing hardwood charcoal, coke, barium carbonate, and sodium carbonate. Full details are given. OWE (10c)

Case Carburizing in Fused Cyanides. H. B. Northrup. *Iron & Steel Industry & British Foundryman,* Vol. 5, Nov. 1931, pages 51-52.

Case carburizing in fused cyanides is least understood of all methods of case carburizing. Molten NaCN has both a carburizing and a nitriding action upon steel. Nitriding occurs when the steel is immersed in the bath, and as the temperature rises action becomes more carburizing and less nitriding, at 1550° F. the nitriding function almost ceases. Bath concentrations are maintained at 25% NaCN, it being diluted with NaCl and Na_2CO_3. CHL (10c)

PYRO THE SIMPLIFIED OPTICAL PYROMETER

SELF-CONTAINED, DIRECT READING, RUGGED AND FOOL PROOF

Unique construction enables operator to rapidly determine temperature even on minute spot or fast moving objects.

PYRO OPTICAL has proven its worth in the following industries:

Iron and Steel Foundries, Glass and Ceramic, Gas and Coke Oven, Refractory, Steel Casting, Rolling, Forging Plants, The Laboratory.

In fact, wherever heat above 1400° F. must be measured accurately and quickly.

Let us explain how PYRO OPTICAL can serve you, by keeping a close check on your heat control equipment—recorder or indicator type—for maximum efficiency.

Weight, complete, 3 lbs.

Stock Ranges: 1400° F. to 5500° F.

Bulletins on PYRO Radiation-Immersion-Surface Pyrometers and PYRO Super-Sensitive Radiation Tubes-Rapid Recorders on Request.

Heat Treatment and Carburizing of Steel in Salt Baths. (Die Wärmebehandlung und Kohlung von Stahl in Salzbädern). THEWS. *Die Metallbörse,* Vol. 22, Jan. 23, 1932, pages 98-99.

The procedure of the case hardening process in cyanogen baths is considered at length. The following data are given: 0.25-0.50 mm. depth of case is desired at 850-950° C., which temperature should be maintained during 1-2 hours. Larger depths of 1-1.25 mm. demand 960° C. and 4-5 hours, after which a heat-treatment should be applied (German practice). The number of the various mixtures is boundless. For small parts 30-35 % NaCN + 35-40 % NaCl + 30 % Na_2CO_3 yield a sufficient case. The melting point of this mixture, the stability and economy of which are stressed, is about 640° C. The cyanogen baths exert a carburizing and nitriding effect. At lower temperatures, the latter prevails and stops at about 880° C. In case of steel the following mixture is recommended which should include only the purest materials: 45% $BaCl_2$, 40% NaCl, 15% KCl. The succeeding heat-treatment of the case-hardened steel is carried out in K-Na-nitrate mixtures. In England a 70/30 Na-K-NO_3 mixture at 130° C. has been recently suggested. For special purposes, the following very low melting bath is given: 25 potassium nitrite, 30 potassium nitrate, 20 sodium nitrite and 25 sodium nitrate. EF (10c)

The Nitrogen Hardening of Alloy Steels. (Die Härtung legierter Stähle durch Stickstoff.) O. MEYER. *Stahl und Eisen,* Vol. 52, May 26, 1932, page 514.

Summary of use of Al, Cr, V, Mo and Ti nitrides for nitrogen hardening of alloy steels, originally published in Zeitschrift Verein deutscher Ingenieure, Vol. 76, 1932, pages 317-320. These nitrides are very difficultly soluble in Fe and with pearlite form the characteristically hardened surface of nitrided steel. The very low solubility and conditions of formation for the blending explain the basic difference between case hardening and nitrogen hardening. The particular role played by H in hardening needs explanation. DTR (10c)

Valuation of Carburizing Compounds. (Bewertung von Einsatzmitteln.) H. MUELLER. *Maschinenbau,* Vol. 11, Feb. 4, 1932, pages 55-57.

Provided that the tests are made under equal conditions, a mathematical formula is given to evaluate the usefulness of various compounds. In this formula the following factors are taken into account: Price of the compound, simple and safe application, amount of detrimental components such as S and P, grain size, inclination to sintering, number of repeated applications possible, losses, speed of effect, depth of the carburized zone, gradual transition of the carburized zones, carbon content of the surface (to be about 1%, varying with the purpose of hardening). The factors are discussed at length. Though the formula looks complicated, its usefulness is proved by a number of experiments. RV (10c)

The Nitriding of Iron and Its Alloys. I. Ammonia Dissociation and Nitrogen Absorption in the Nitriding Process. II. Observations on Case Properties of Nitrided Iron and Its Alloys. A. W. COFFMAN. *Industrial & Engineering Chemistry,* Vol. 24, July 1932, pages 751-754; Aug. 1932, pages 849-856.

In contact with the steels under consideration, ammonia decomposition becomes nearly complete at 800° C., while the rate of change of ammonia concentration with the change of temperature becomes a maximum at some definite temperature coincident with the temperature of maximum absorption. The temperature of this coincidence depends upon the steel. Seven references are cited. Observations have been made on the nitriding characteristics of pure Fe and a series of alloys of pure Fe with C and either Mo, Al, Mn, Cr, Ni, or Cu. All alloys investigated showed a critical temperature for maximum nitrogen absorption. This temperature varied with the chemical composition of the alloy. Pure Fe absorbed more nitrogen than any of the alloys, while addition of any other element decreased nitrogen absorption to a large degree. Great ability of an alloy to absorb nitrogen does not necessarily mean great hardness. Nitrogen penetrated pure Fe more readily than its alloys. The greatest resistance to atmospheric corrosion was developed by nitriding an alloy at the temperature at which the alloy absorbed a maximum amount of nitrogen. It has been shown that maximum hardness is not to be expected when maximum corrosion resistance is obtained. MEH (10c)

On the Nitriding of Iron and Iron Alloys. I. (Ueber die Nitrierung von Eisen und Eisenlegierungen. I.) W. EILENDER & OSKAR MEYER. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule Aachen,* Vol. 11, 1932, 10 pages.

A Suitable Hardening Compound. (Ein brauchbares Härtemittel.) C. DINGELSTEDT. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur- Betriebstechnik,* Vol. 65, Apr. 10, 1932, pages 50-51.

The properties of normal and particularly of burned steel are claimed to be considerably improved by packing the steel before quenching in the compound "Restavem" (composition not given). The structures given actually show an improvement and the results of physical tests seem to prove the claim. It is claimed that not only the structure of superheated but even of totally burned steels can be regenerated by Restavem. Examples are given which show that the properties of quenched burned steels were even better than that of steels with a normal structure. GN (10c)

Quenching (10d)

Some Remarks on the Paper by Captain Chanzy on Quenching Cracking. (Note au sujet du mémoire de M.le Capitaine Chanzy sur les tapures de trempe.) A. SOURDILLON. *Revue de Métallurgie,* Vol. 29, June 1932, pages 301-305.

The data presented by Chanzy (*Revue de Métallurgie,* Vol. 29, June 1932, pages 281-300) were checked experimentally and the shape of the cooling curves was verified. The use of furnaces for subdivided quenching must be restricted in the light of the cooling media employed in them. Hot air is not, for example, sufficient to produce the same effect as the cool air of the usual practice. As long as there is a definite critical speed of the decomposition of austenite the cooling medium must produce it in the first stages of cooling. Davenport and Bain's results (*Technical Publication* 348, *American Institute Mining & Metallurgical Engineers*) show that austenite decomposition at a constant temperature under 300° C. results in martensite alone while above it troostite and pearlite are formed. Using the baths as recommended by Chanzy care must be taken to adjust their temperatures so that the range would be small enough to prevent cracking while the lower limit of it would be low enough to prevent other than martensitic decomposition even when the steel is left at it for some time. JDG (10d)

Quenching of Alclad Sheet in Oil. HORACE C. KNERR. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 487-493.

Aging (10f)

Structural Hardening at High Temperatures of the Alloys of Iron and Tungsten (Durcissement structural a chaud des alliages fer-nickeltungstene). A. PORTEVIN, E. PRETET & H. JOLIVET. *Comptes Rendus,* Vol. 194, Apr. 11, 1932, pages 1237-1239.

Precipitation hardening has hitherto been applied in the main to the improvement of the mechanical properties of alloys at room temperature. The phenomenon, however, may be used to increase the strength of alloys at any temperature of utilization. This object may be attained by choosing an alloy which will be employed in service at temperatures corresponding precisely with those at which precipitation proceeds. The authors have investigated the possibility of increasing the strength of an alloy during use at high temperatures. In their experiments they examined a series of alloys of Fe, Ni and W, and in particular a group of such alloys containing 33% Ni. Using dilatometric and micrographic means, they have determined the solid solubility in Ni-austenite of a constituent which they referred to as "X," at temperatures varying between 800° and 1350° C. The results of their experiments are shown graphically. The precipitation of the dissolved constituent from the austenite, which becomes quite noticeable at 650° C., increases in rapidity at temperatures between 850° and 950° C. (according to the composition of the alloy). This precipitation results in an increase in the hardness of the alloys at room temperatures. That such an increase in hardness does occur has been shown by means of compression tests on an alloy containing 30% Ni and 25% W. Curves showing the results of these tests accompany the paper. The following test results are quoted for the 30/25 and 30/30 alloys, respectively.

Condition of Alloy	30/25	30/30
As cast	15.4 kg./mm.^{2}	26.7 kg./mm.^{2}
After 24 hr. at 850° C.	33.5 kg./mm.^{2}	37.0 kg./mm.^{2}

The possible importance of this effect upon the forgeability of these and other alloys is commented upon by the authors who note that analogous results may be expected when Mo is substituted for W in these alloys. They opine that the rate of precipitation of the solute compound may be modified quite considerably by the addition of such elements as Si or Cr. OWE (10f)

Age Hardening of Copper Steel. S. STEINBERG & W. SUDOW. *Iron Age,* Vol. 129, Feb. 4, 1932, page 330.

The Aging of Steel. (Die Alterung des Stahles.) HERBERT MÜLLER. *Zeitschrift des bayerischen Revisionsvereins,* Vol. 36, June 30, 1932, pages 139-142.

The paper surveys the present status on the aging of steel and considers magnetic aging, mechanical aging and its influence on hardness, elongation and notch toughness. The influence of N, O, P, and Cu on the aging properties is discussed. Most significant for occurrences of aging is the increase of hardness in combination with a change of the capacity for deformation. In aging steels the transition zone from high to low values on the notch toughness—temperature curve is shifted to higher temperatures but the maximum values of notch toughness are lower than in non-aging steels. The occurrences of aging are compared to those in hardened steels. The effect of work hardening on the disintegration of supersaturated solid solutions and the possibilities of suppressing precipitations are pointed out. Brief mention of the processing of non-aging steels (Izett steel). 12 references. GN (10f)

Age-hardening of Austenite. F. R. HENSEL. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 255-283.

Brazing (11a)

Boric Acid and Brazing. (Borsäure und Hartlötung.) ABUCH. *Deutsche Goldschmiedezeitung,* Vol. 35, Aug. 6, 1932, pages 2-3.

Suggestions as to the use of boric acid in brazing pieces of jewelry. GN (11a)

Soldering (11b)

Soldering the Stainless Steels. V. W. WHITMER. *Welding Engineer,* Vol. 7, Apr. 1932, page 31; *Metalcraft,* Vol. 8, Apr. 1932, page 172; *Steel,* Vol. 90, Apr. 4, 1932, page 40; *American Machinist,* Vol. 76, May 26, 1932, page 676.

As soldering is a joint of surface adhesion only the surfaces should be roughened to obtain a reliable union. This can be done by a rough file, emery wheel, or with a mixture of 50 parts ferric chloride in 100 parts HCl diluted 2 or 3 to 1 when applying to the surfaces. The surface is then suitable for tinning. The piece must be carefully cleaned afterwards. Ha+VVK+JN (11b)

Cadmium Solders for Soldering Silver. (Kadmiumlote zum Löten von Silber.) *Deutsche Goldschmiedezeitung,* Vol. 35, May 14, 1932, page 4.

A Ag solder with 30% Cu, 30% Zn, 20% Ag and 20% Cd has a high plasticity and strength and very low melting point. With increasing content of Ag and Cd the solders become thinner liquid but the tensile strength decreases. GN (11b)

Hard-Soldering of Aluminum. (Das Hartlöten des Aluminiums.) *Aluminium,* Vol. 14, May 31, 1932, pages 5-6.

A hard solder for Al contains at least 70% Al, the remainder is other metallic elements. A flux of the halides of the alkali metals is used. The flame must not be too hot, air-illuminating gas or air-acetylene is sufficient. The joint is very strong and can replace in some cases the welding which is usually employed for pure Al. Ha (11b)

Welding & Cutting (11c)

Importance of Welding Quality in Stainless Alloys. *Welding Engineer,* Vol. 17, Jan. 1932, page 37.

All stainless alloys now on the market are divided in 6 groups:

	% C	% Cr	% Si	% Ni
Group 1	over 0.20	12-16	....	....
" 2	less than 0.12	12-15	....	....
" 3	less than 0.12	16-20	0.50–1.50	....
" 4	.....	17-25	....	7.12
" 5	.....	7-25	....	17–22
" 6	less than 0.3	20-30	....	....

All of these can be welded. Welds made with groups 1, 2, 3 require heat treating to remove the brittleness produced next to the base metal. Group 4 which contains the majority of the stainless steels now on the market, welds very satisfactorily and leaves base metal and weld ductile after welding; they can even be cold-drawn. If castings are made of the alloys given in the table it is necessary that they be heat-treated after welding to obtain the maximum resistance to either heat or corrosion and to improve the strength and ductility of the casting. Ha (11c)

Non-Ferrous Metals. *Welding Engineer,* Vol. 17, Apr. 1932, pages 25-26.

General information on the best procedure of welding Everdur (96% Cu, 3% Si, 1% Mn) and Al is given and operation of torches and use of auxiliary tools explained. Ha (11c)

Electric Resistance Welding and High Speed Production. C. A. HADLEY. *Welding Journal,* Vol. 29, July 1932, pages 198-204.

Includes discussion. Paper read before the Members of the Midlands Branch of the Institution of Welding Engineers, Birmingham, Feb. 19, 1932. A study of the effect of time and current values is of great importance in production of quality spot welds. The author explains the physical and metallurgical effects of spot welding at various speeds. In order to avoid distortion and to obtain optimum efficiency the weld must be made at that speed which will heat the joint to a welding temperature but leave the external surface cold and unaffected. TEJ (11c)

The Strength of Arc Welded Joints. FRANK RICHARD FREEMAN. *Journal American Welding Society,* Vol. 11, June 1932, pages 16-24.

Extracts from paper presented before the Institution of Civil Engineers, Proceedings Institution of Civil Engineers, Vol. 231, Session 1930-1931, Part II. An investigation of arc welded full sized joints of all common types. The following strengths may be expected for the various types of joints. Longitudinal shear fillets, 4.8 tons/in. of ⅝" fillet; Transverse fillets, 8.0 tons/in. of ⅝" fillet; Butt welds, 16 tons/in.² of weld. For compound welds the allowable stress is a mean of the strength of the transverse and longitudinal fillets and exceeds the strength of the longitudinal fillet by an amount proportional to the angle of slope of the length of the fillet to the axis of stress. Physical properties of all weld metal specimens are given. TEJ (11c)

Welding of Cast Electron Housings. (Schweissen von Elektronguss Gehäusen.) HANS A. HORN. *Autogene Metallbearbeitung,* Vol. 25, May 1, 1932, pages 135-138.

Electron castings are used extensively in the construction of automobiles and aeroplanes; it contains up to 90% Mg and between 4 to 10% Al, 3% Zn, and 0.2 to 0.5% Mn. The cast material has a specific gravity of 1.8 and a melting point of 620° C. The tensile strength of 17 to 23 kg/mm.² is always attained and even exceeded in the welds. Its behavior in the flame is quite different from Al and its alloys on account of its inflammability. Special electron welding rods must be used. Welded pieces should not be moved until cold as they easily deform; the welder must therefore be very skillful to use his torch in all positions, especially overhead. The welding flame should be only half as hot as for Al welding. The preparation and treatment of the pieces before and after welding is described and a few examples of repairs illustrated. Ha (11c)

Arc Welding in Tramway Operation. (Lichtbogenschweissung im Strassenbahnbetrieb.) G. HAFERGUT. *Elektroschweissung,* Vol. 3, Aug. 1932, pages 151-154.

The savings to be effected by street railways by repairing and building cars, track parts, etc. by electric welding are dealt with. Welding of rails and frogs is discussed. Rail joint testing is briefly touched upon. 2 references. GN (11c)

On the State of Stress and the Strength of Weld Seams. (Ueber den Spannungszustand und die Festigkeit von Kehlnähten.) E. HÖHN. *Schweizerische Bauzeitung,* Vol. 99, May 14, 1932, pages 257-260; May 21, 1932, pages 263-266.

Extensive experimental investigations and calculations on the state of stress in weld seams. Determinations of stresses in seams. 9 references. GN (11c)

Repairing Oil Trunk Lines by Arc Welding. ALBERT N. HORNE. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Petroleum Mechanical Engineering, pages 33-35.

Data are given for repairing oil trunk lines by electric welding without interruption of service. Corroded or pitted lines can be patch-welded very economically. Ha (11c)

Methods of Controlling Arc Blow. R. W. HOLT. *Welding Engineer,* Vol. 17, Mar. 1932, pages 40-42; Apr. 1932, pages 44-46.

The electromagnetic causes of the arc being blown about are explained and the means for obtaining a steady arc discussed. The ground contact must be properly placed, that is, it should be in the rear of the traveling direction of the arc. Tipping of the electrodes, back-stepping, tacking, etc., are some of the more often applied remedies. Sketches illustrate the causes and remedies clearly. Ha (11c)

The Reinforcement of the Paradise Bridge in Zwickau (Saxony) by Electric Arc Welding. (Die Verstärkung der Paradiesbrücke in Zwickau i.Sa. im Elektroschweissverfahren.) F. HEMPEL. *Bautechnik,* Vol. 10, Apr. 8, 1932, pages 211-213.

The paper describes the reinforcement of the main and cross beams of the bridge by electric arc welding. Coated electrodes 4 mm. in diameter were used. GN (11c)

Ductility in Arc Welds with Some Reference to Strength Values. CHAS. H. JENNINGS. *Journal American Welding Society,* Vol. 11, July 1932, pages 28-29.

Discussion by J. C. Lincoln of paper published in *Journal American Welding Society,* Vol. 11, Apr. 1932, pages 37-42. TEJ (11c)

The Application of Electric Arc Welding in the Construction of High Pressure Vessels. (Die Anwendung der Lichtbogenschweissung beim Bau von Hochdruckbehältern.) E. JOELLENBECK & C. MASSMANN. *Elektroschweissung,* Vol. 2, Sept. 1931, pages 165-169.

The experiments reported are aimed to furnish data on the qualification of electric arc welding for producing thick-walled vessels. Welds were tested with the following results: Tensile strength and yield point of the welded parts are higher than that of the base metal, even at temperatures up to 500° C. The elongation is approximately the same as for the base metal, except for testing temperatures from 400° to 500° C. At these temperatures a decrease of the elongation takes place. The notch toughness is rather low. However, endurance bending and impact tests show that low values of notch toughness are of no great significance. X-ray radiographic examinations showed minor pores in some of the welds; the decrease of cross-section thus effected is more than compensated by the increase of tensile strength and yield point. The resistivity against corrosion of the welds was also tested. The results justify a higher valuation of good electric welds. The loads permitted for water gas welds should also be permitted for electric welds. GN (11c)

Procedure for Welding Large Everdur Pressure Vessels. CHARLES B. JACOBS. *American Machinist,* Vol. 76, Feb. 25, 1932, pages 272-274.

Describes the welding operations used in welding 2 Everdur tanks of 10,000 gal. capacity. By use of a reinforcement bead the strength of the weld slightly exceeded that of the parent metal. RHP (11c)

Welding Progress at the A. O. Smith Plant. T. MCLEAN JASPER. *Transactions American Society of Mechanical Engineers,* Vol. 54, Mar. 30, 1932, Petroleum Mechanical Engineering, pages 11-13.

A general description of the development of welding pressure vessels, testing equipment and test methods with some test results. Ha (11c)

Repair Welding of Cast Iron Armatures. (Reparaturschweissungen an gusseisernen Strassenarmaturen der öffentlichen Betriebe.) H. JÜRGENS. *Gas und Wasserfach,* Vol. 75, Feb. 6, 1932, 108-111.

In order to obtain welding seams of high strength, good corrosion resistivity and easy machinability the following points are to be observed: proper adjusting of the welding flame, selected filling rods and fluxes. Examples are shown of the welding of hydrants, public wells, lampposts, etc. GN (11c)

Electric Lay-on Welding in Street Railway Operation. (Elektrische Auftragsschweissung im Strassenbahnbetrieb.) HANS A. HORN & KARL TEWES. *Elektroschweissung,* Vol. 3, June 1932, pages 113-115.

The paper discusses the rules for properly filling up the grooves of worn tramway rails by welding. The duration of rails can thus be increased considerably. The following 3 types of welding rods are chiefly used in Germany.

Material	C %	Mn %	Si %	P %	S %	W %	Cr %
A	1.10	.25	.25	.04	.03	..	..
B	1.00	~14.0	.30	.08	.05	..	..
C	1.10	.30	.20	.03	.03	1.5	.8

In most cases A is used giving a Brinell hardness of from 280-320. B is austenitic, C gives a hardness up to 500. Proper choice of welding current and arrangement of the seam is emphasized. GN (11c)

Installing Pipes By Welding. (Rohrinstallation mit Schweissung.) W. JOHAG. *Gas und Wasserfach,* Vol. 75, Feb. 20, 1932, pages 148-151.

The paper surveys the principles to be borne in mind in the oxy-acetylene welding of pipes. In general, preparation of the weld seam is not necessary in common practice. The testing of welds is discussed. GN (11c)

Brands of Welding Wires and Their Testing. (Schweissdrahtsorten und Schweissdrahtprüfungen.) Fr. Huth. *Emaille-technische Monatsblätter,* Mar. 1932, pages 20-21.

General discussion. Welding wires must be entirely free from rust, scale, sand and oil. The surface is suitably examined with magnifying glasses. In order to simplify the testing the welding wires should be standardized. GN (11c)

Pressure Welding of Low-Carbon Steels with Theoretical Considerations on the Mechanism of such Welding. I, II. C. R. Austin & W. S. Jeffries. *Journal American Welding Society,* Vol. 11, June 1932, pages 24-33; July 1932, pages 30-37.

Paper presented before the annual meeting of the American Institute Mining & Metallurgical Engineers, New York, Feb. 1932. See *Metals & Alloys,* Vol. 3, Apr. 1932, page MA 100. TEJ (11c)

New Welding Blowpipe Has Been Developed for Oxyacetylene Welding. T. W. Greene. *Oil & Gas Journal,* Vol. 30, Apr. 21, 1932, page 48.

Paper before the American Gas Association Distribution Conference. A description of a new oxyacetylene welding blowpipe (Linde-Weld process of the Linde Air Products Co.) by which a welding speed of 3 to 3½ times that of the present process is obtained. See also "A New Process of Oxy-Acetylene Welding," *Metals & Alloys,* Vol. 3, Apr. 1932, page MA 100. VVK (11c)

Electrically Welded Bridge. (Elektrisch geschweisste Brücke.) Stefan Bryla. *Elektroschweissung,* Vol. 3, Aug. 1932, page 158.

Description of construction and welding of a bridge built in Lowicz, Poland. GN (11c)

Notes on Arc-Welding in Bridgework in Australia. W. D. Chapman. *Iron & Coal Trades Review,* Vol. 124, June 17, 1932, page 995.

Up to the present 136 bridges (highway and railway) have been repaired or constructed by arc-welding in Australia since 1924. The main applications in repair work have been relief of rivet stresses, the addition of extra section to flanges of plate girders and truss members, stiffening of long columns, correction of minor faulty details and repair of wastage of section due to corrosion. Advantages as compared with older method were less cost, and less interference to traffic. New welded bridges are used so far only for joist or broad-flange beam spans, but these yielded considerable savings over the older riveted methods. Mild steel covered electrodes were used exclusively. The work has been proved to be absolutely satisfactory. Ha (11c)

What Does It Cost to Weld Pipe Fittings? Arthur E. Christen. *Welding,* Vol. 3, July 1932, pages 429-434; Aug. 1932, pages 488-490.

A discussion of the time and materials required for oxy-acetylene welding various pipe connections. TEJ (11c)

Flame Cutting of Low-Carbon Steel. J. R. Dawson. *Journal American Welding Society,* Vol. 11, June 1932, pages 5-6.

Paper presented at the Oct. 20, 1931, meeting of the New York Section of the American Welding Society. Precision flame cutting of steel is possible with the modern cutting torch. Higher C and alloy steels are usually preheated before cutting while low C steels do not require preheating. TEJ (11c)

The New Symbols for Welded Joints according to German Industrial Standards 1912. (Die neuen Zeichen für geschweisste Verbindungen nach DIN 1912.) A. Hilpert. *Autogene Metallbearbeitung,* Vol. 25, June 1, 1932, pages 161-162; *Stahlbau,* Vol. 5, Aug. 5, 1932, pages 127-128.

The new German Standard symbols for welded joints, welding process and their designations are reproduced in full. Ha+GN (11c)

A New Welding Material for Manganese Steel. John Howe Hall. *Iron Age,* Vol. 129, Mar. 3, 1932, page 540; *Welding Engineer,* Vol. 17, Jan. 1932, pages 39-41.

Describes a special Mn steel developed by the Taylor-Wharton Iron & Steel Co. known to the trade as "Timang". Its chemical composition is 0.60 to 0.80% C, 12 to 15% Mn and approximately 3% Ni. In addition to its use as a welding material for Mn steel "Timang" is made in the form of castings, rods, plates and sheets. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 310. VSP+Ha (11c)

Modern Welding Methods, Fusion Welding, Electric Resistance Welding, Cutting. (Neuzeitige Gas-, Elektro-, Gas-elektro-, Flammverschmelzungsverfahren, elektrische Widerstandsschweissung und Brennschnitt.) Krynes. *Zeitschrift des Österreichischen Ingenieur- und Architektenvereins,* Vol. 84, Mar. 11, 1932, pages 48-49; June 3, 1932, pages 112-115.

Report on papers before the Fachausschuss für Schweisstechnik of the Osterreichischen Ingenieur-und Architektenvereins. GN (11c)

The New Resistance Welding. M. L. Eckman. *Welding Engineer,* Vol. 17, Feb. 1932, pages 42-44.

A general discussion of present methods, machinery and quantity production. Speed and uniform quality are best obtained with this welding method. Ha (11c)

The Costs of Electric Arc Welding. (Die Kosten der Lichtbogenschweissung.) Walter Mohr. *Elektroschweissung,* Vol. 3, July 1932, pages 132-134.

The paper considers the costs of electric arc welding under the following groupings: (1) material, (2) wages, (3) current, (4) depreciation, maintenance, interest, (5) charges. The factor of prime importance is the welding time. The welding time should be abbreviated by suitable devices, automatic welding, suitable electrodes, etc. GN (11c)

Inspection and Tests of Welding in Structures. F. Eder. *Journal American Welding Society,* Vol. 11, June 1932, pages 11-15.

Paper presented at the Apr. 1932 meeting of the Philadelphia section of the American Welding Society. For consistent and proper quality of welding in shop and field it is essential that a competent inspector supervise the welding operations, systematically throughout the whole period during which welding is done. The author gives details of arc and gas welding procedure, pointing out those important details which the inspector should particularly note. Tests to determine quality of welds are suggested. TEJ (11c)

Fusion Welding and its Application for Storage Batteries. (La Soudure Autogene et son Application aux Accumulateurs.) C. Franche. *L'Industrie Electrique,* Vol. 41, Feb. 25, 1932, pages 87-88.

It is pointed out that in spite of the great heat of the oxy-acetylene flame it is suitable for welding Pb with its low melting point if the flame is made very small so that the intense local heating effect is utilized. In that case, the process is very economical, about 25 l. gas/hr. are consumed. The particular application for the assembly of storage batteries is illustrated. Ha (11c)

Concerning Crater Formation. Gilbert E. Doan. *Journal American Welding Society,* Vol. 11, July 1932, pages 17-18.

Crater formation in arc welds is caused by (1) lowering of surface tension of the liquid Fe at the center of the molten puddle due to the higher temperature at that point; (2) pressure of a gas or electron stream that seems to originate at the electrode tip and blow the metal outward from the center of the molten puddle. TEJ (11c)

Spot-Welded Stainless in Aircraft Construction. C. De-Ganahl. *Welding Engineer,* Vol. 17, June 1932, pages 30-31.

The process of electric spot-welding 18-8 alloy is described. Safe welds require very exact timing and good metallurgical knowledge of the material; heated to between 500° and 900° C. the C has a tendency to come out of solution and to combine with Cr to form Cr carbide which leads to a dangerous corrosion. With the electric method the heating and cooling is so rapid that the C has no time to come out, while this easily occurs with gas welding. Ha (11c)

Influence of the Fiber Direction on the Tensile Strength in Electric Resistance Welding. (Einfluss der Faserrichtung auf die Festigkeit bei der elektrischen Widerstandsschweissung.) Füchsel. *Elektroschweissung,* Vol. 3, Aug. 1932, pages 147-148.

In electrically welding together vertical plate-shaped pieces which have a fibrous structure with prismatic or tube-like pieces, the parts joined show at least the tensile strength of the base metal when the fiber direction of both of the pieces to be joined is vertical to the welded face. This statement was found to be substantiated on German standard steels: St. 37, C about .1%; St. 50, C about .35%. GN (11c)

Pipe Line Welding as Seen From Standpoint of User of Welding. R. S. Fuller. *Oil & Gas Journal,* Vol. 30, Apr. 21, 1932, pages 45-47.

Paper presented before the American Gas Association Distribution Conference. A very comprehensive discussion of pipe line welding from the standpoint of the welder and the pipe line layer. VVK (11c)

Welded Rail Joints. (Der Schweissnahtstoss). J. Franke. *Zeitschrift des Österreichischen Ingenieur-und Architektenvereins,* Vol. 84, Feb. 12, 1932, pages 24-25.

Description of some methods of joining rails by welding. Special type fish-plates are suitably used. GN (11c)

The Structure of Welds of Soft Steels. (Ueber das Gefüge der Schweissungen von weichen Stählen.) H. Gerbeaux. *Die Schmelzschweissung,* Vol. 9, June 1932, page 132.

Soft steels with not more than 0.3% C which consist exclusively of ferrite crystals and pearlite fields of small area show the following changes at welding with the oxy-acetylene flame: The material close to the weld is heated whereby at first an increase in the grains is produced which later is reduced as the size of the grains increases. The rapidly solidifying material shows numerous crystallization centers so that the structure of the fused material becomes similar to the heated material in the neighborhood. The metal grows inversely to the cooling velocity and its size depends especially on the velocity with which it passes through the Ar_3 point. Below this transformation point, the ferrite begins to separate from C. When Ar_1 is reached pearlite is precipitated. The grain of the weld is coarser than that of the metal resulting in a reduction of the notch-toughness of the weld. The elongation decreases and the hardness increases slightly. Ha (11c)

Welding Monel Metal Dye-Handling Equipment. *Textile World,* Vol. 81, Apr. 16, 1932, page 41.

Dye measuring equipment, dye receivers and scoops for handling dry and liquid dyes are made of Monel metal sheets and welded by the oxy-acetylene torch. Ha (11c)

Electric Welding of Thick Walled Vessels. (Elektroschweissung dickwandiger Gefässe.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, May 29, 1932, page 292.

This is the abstract of a paper by W. Prox before the Committee on Welding Technique of the Verein deutscher Ingenieure, Apr. 22, 1932. Arc welds with common uncoated wire show insufficient plasticity and notch toughness. N was found to be the reason of this brittleness. (See the simultaneously published paper by F. R. Hensel & E. I. Larsen: Age Hardening Phenomena in typical fusion-weld metal. *Transactions American Society for Steel Treating,* Vol. 19, May 1932, pages 639-672). Besides N, O and S impair the mechanical properties of the weld. Comprehensive tests were carried on with all types of welding wires on the market in Germany. New suitable coated wires were developed for the new Pintsch welding method which is not described in the paper. Structures of welds made according to the new method show that the C does not burn during welding, pearlite shows the same structure as in the base metal, needles of nitrides are absent. Unannealed Pintsch-welds show a notch toughness of from 10.3—13.6 mkg/cm.², after annealing to eliminate stresses a notch toughness of from 11.5 to 15.3 mkg/cm.². The advantages of machine welding are pointed out. GN (11c)

Electric Welding in Ship Construction. *Engineering,* Vol. 133, Feb. 12, 1932, page 183.

Brief comment on recent publication of the British Corporation Register of Shipping and Aircraft entitled "Provisional Rules for Electric Arc Welding in Ships." LFM (11c)

WORKING OF METALS & ALLOYS (12)

Production of Aluminum Foil. (Herstellung von Aluminiumfolie.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, May 22, 1932, pages 277-278.

Description of the processing of Al foil from ingot to the finished foil. GN (12)

Melting & Refining (12a)

The Melting of Metals in Modern Oil Furnaces. (La Fusion des Métaux dans des Fours à Huile Moderne.) *Revue de Fonderie Moderne,* Vol. 26, June 25, 1932, pages 207-208.

The purity of metals melted in a crucible can also be obtained in larger quantities in open-hearth furnaces with proper flames. The use of fuel-oils and the advantages are discussed briefly; among the latter is particularly the lower burning of Zn and Cu, and usually the slag can rise better to the surface which is of importance in the melting of Al. Ha (12a)

Coreless Induction Furnaces. *Iron & Coal Trades Review,* Vol. 125, July 1, 1932, page 13.

The advantages of the coreless induction furnace in melting of alloy scrap are economy, easy control of the temperature and reduction of contamination of the metal to a minimum. A few examples illustrate this. Ha (12a)

The Application of Deoxidizing Materials at the Finish of the Charge in Acid and Basic Open Hearths. Short Literature Survey. (Om användning av desoxidationsmedel vid avslutning av chargen i sur och basisk martinung. Kort litteraturöversikt.) S. Ekelund. *Jernkontorets Annaler,* Vol. 116, May 1932, pages 231-243.

A review. HCD (12a)

The Acid Electric Furnace in the Steel Foundry. (Der säure Elektroofen in der Stahlgiesserei.) R. Genwo. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 10, 1932, pages 274-277.

Whereas most of electric steel in U. S. A. is made in acid furnaces, most of the electric steel in Germany is made in basic furnaces. The paper discusses at length the mode of operation of acid furnaces for straight C as well as alloy steels. The high capacity, cheap furnace lining and maintenance, simplicity of operation and good properties of acid electric steel are particularly pointed out. GN (12a)

Preparation of Pure Magnesium by Sublimation. (Herstellung von reinem Magnesium durch Sublimation.) *Die Metallbörse,* Vol. 22, Mar. 9, 1932, page 307.

Highly pure Mg is obtained at a rapid rate by sublimation at 600° C., i. e. 150° C. below its melting point, at a pressure of 0.01 mm. Hg. The metal deposited on water-cooled plates contains less than 0.001% Si. Small contaminations of NaCl and $MgCl_2$ show up at the surface. EF (12a)

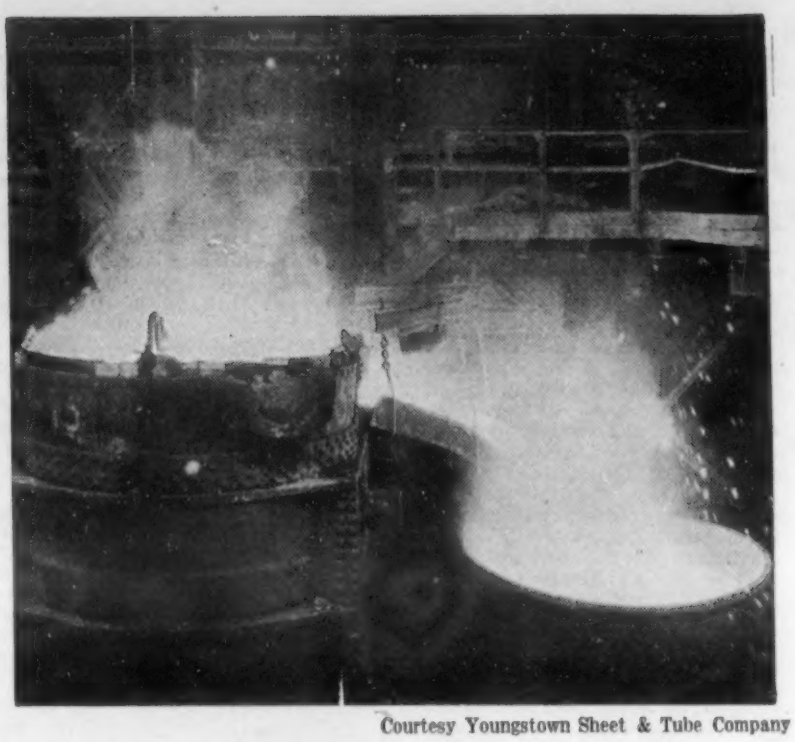
The Design and Operation of Open-Hearth Furnaces. C. W. Veach. *Rolling Mill Journal,* Vol. 5, Aug. 1931, pages 527-530; Sept. 1931, pages 587-590; Nov. 1931, pages 707-709; Dec. 1931, pages 767-770, 790-791.

Discusses the procedure of charging lime into the open-hearth furnace, describes the principles of combustion and discusses the means and necessity for control of the bath temperature and the oxidation conditions and slag building. Ha (12a)

Design and Operation of Open-Hearth Furnaces. XIII-XVI. C. W. Veach. *Rolling Mill Journal,* Vol. 6, Jan. 1932, pages 23-24, 29-30; Feb. 1932, pages 63-65; Mar. 1932, pages 97-98; Vol. 7, No. 1, 1932, pages 47-54, 57-58.

General discussion of the chemistry of the open-hearth process. Deals with chemical properties of Fe and its oxides; sources of Fe oxides; Si and SiO_2; Mn and MnO; deoxidation by means of Mn; P and P_2O_5; S and sources of S; C, CO and CO_2; and effect of P on steel. Advocates high residual Mn. MS (12a)

How Metal Castings Are to be Deoxidized. (Wie muss der Metallguss desoxydiert werden?) R. Berger. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Apr. 3, 1932, pages 144-145.



It is emphasized that in deoxidizing metal melts it is of extreme importance to submerge the deoxidizing metal under the surface of the melt when a careful deoxidation is to be attained. Suitable methods of submerging the deoxidizer are described. Submerging bells made of cast iron are excellent. The handling of such bells is outlined. GN (12a)

Notes on the Heredity Phenomenon due to the Introduction of Steel Turnings and Means to Obviate these Inconveniences. (Considerations sur les Phenomenes d'Heredite dus a l'Introduction de Robbons d'Acier et sur les Moyens d'obvier a ces Inconveniants.) M. Boutigny. *Revue de Fonderie Moderne,* Vol. 26, Feb. 25, 1932, pages 57-60.

The author deals with the differences which are often observed in the quality of steel produced in exactly the same manner, in the same furnace and of the same constituents. The principal reason is found in the scrap added to the charge, and especially if the scrap contains turnings from machining of steel pieces. The nature of the scrap should, therefore, be very well known and its amount with respect to the new material determined accordingly in order to obtain a material of the quality desired. Several examples illustrate the procedure; the ratio of scrap to new material is calculated from the chemical analysis. For the melting of such charges the rotary furnace is very advantageous, especially in smaller sizes shorter melting times and greater flexibility for different conditions are obtainable. Ha (12a)

Electric Furnaces for Melting of Metals and for the Production of Ferro-Alloys. (Elektroöfen zum Schmelzen von Metallen und zur Herstellung von Ferrolegierungen.) Reinhold Gross. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Apr. 9, 1932, pages 353-358.

The paper reviews the principal lines of progress of arc furnaces and low and high frequency furnaces, some new installations are described and energy consumptions tabulated for melting of steel and Ni. The present trend is not only to use larger furnace units but the quality and economy have progressed so much that they are used almost exclusively for ferro-alloys and chemico-thermal processes. The Solidification and Crystallisation of Steel Ingots: the Influence of the Casting Temperature and the Undercooling Capacity of the Steel. B. MATUSCHKA. *Engineering*, Vol. 132, Oct. 16, 1931, page 484. See *Metals & Alloys*, Vol. 3, Mar. 1932, page MA 73. LFM (12b)

Bottom Cast Practice. II, III. EDMUND C. BITZER. *Blast Furnace & Steel Plant*, Vol. 20, Feb. 1932, pages 175-178; Mar. 1932, pages 262-264, 267.

Most serious defect of bottom-cast ingots is cracking. Cracks can always be traced to unequal cooling conditions, the chief cause of this being a rapid pouring rate. 2 methods are available in preventing cracked ingots. One is to control cooling conditions directly by pouring the steel within particular temperature limits, and the other is to regulate the speed of pouring in such a manner as to obtain even cooling. First method depends on an accurate knowledge of the temperature of the steel and is not practical because of unreliable methods of measurement. The second may be carried out by regulating the nozzle size or by changing the number of molds per group to increase or decrease the pouring rate as desired. Unevenly heated molds will also cause cracked ingots. Tabulates tapping and casting temperatures and percentage of cracked ingots. Another table gives information on size of nozzles, pouring speed by groups and percentage of cracked ingots produced. Data indicate that for round ingots 13″ and less in diam., rate of pouring should not exceed 150 lb./sec. For larger sizes, 200 lb./sec. is permissible. Part III. Another cause of cracking is deflection of the stream of metal to one side of the mold during pouring. Minor ingot defects are surface overlaps, surface blow-holes and shrinkage cavities around the sprue on the base of ingots. Inclusions must be prevented. Their principal cause is dirt in the steel runner on the furnace, in the ladle and in the runner brick. Ability to control pouring speed should be considered in ladle design. Ratio of cross-sectional area to height should be large. Oval-shaped ladles meet this requirement. Ideal nozzle is one that will enlarge at a rate which will maintain the pouring rate constant, but this is hard to realize. Curves show pouring characteristics of certain nozzles. With clay nozzles, pouring rate increases to a maximum and then diminishes. With magnesite or graphite nozzles, pouring rate drops as the head of metal in the ladle decreases. Any grade of steel can be bottom cast. Killed steel with 0.10-0.25% C gives the least trouble. Rimmed steel should have the proper amount of gas evolution when the steel is poured. Greatest danger in bottom casting small ingots of rimmed steel lies in pouring the ingots too high. Greater care is necessary in deoxidizing rimmed steel for bottom casting than for top pouring. MS (12b)

Babbitting Steel Shell Bearings. ROBERT JONES. *Foundry Trade Journal*, Vol. 46, May 26, 1932, page 329. A description of equipment for babbitting steel shell bearings. OWE (12b)

The Effect of the Ingot Temperature on the Location of Blow Holes and the Segregation of Soft Steel Ingots. (Der Einfluss der Kokillentemperatur auf die Lage der Randblasen und auf die Seigerungsverhältnisse in weichen Flussstahlbrammen.) AUG. STADELER & H. J. THEILE. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen*, Vol. 11, 1932, 12 pages.

See *Metals & Alloys*, Vol. 2, Nov. 1931, page 270. Ha (12b)

Improved Facing Material for Permanent Molds. (Verbesserte Anstrichmasse für Dauerformen.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, June 26, 1932, page 261.

In the new facing material the ingredients such as graphite, talcum, clay, are not suspended in water but are in actual solution which condition is attained by a special process of colloidizing. It is to be used particularly for casting Al in permanent molds. The thinner the solutions the better the facing material clings to the mold. GN (12b)

The Centrifugal Casting Process as Applied to Non-Ferrous Metals and Alloys. J. E. HURST. *Metal Industry*, London, Vol. 40, Jan. 15, 1932, pages 88-92. The application of centrifugal casting to brasses, bronzes and Cu-Ni alloys, including Si bearing Monel metal, is described. PRK (12b)

Instructions for the Pouring of Machinery and Motor Bearings with White Metal. (Vorschriften zum Ausgiessen von Maschinen- und Motorenlagern mit Weissmetall.) C. KROEMER. *Automobiltechnische Zeitschrift*, Vol. 35, June 10, 1932, pages 284-286; *Die Werkzeugmaschine*, Vol. 36, July 31, 1932, pages 260-262.

A very good composition of a bearing metal is given as 75-83% Sn, 12-15% Sb and 3-5% Cu; no Pb must be added. Heating, method of pouring, avoidance of waste, preheating of bearing into which the metal is poured, etc., are treated. Ha+GN (12b)

Density and Hardness of Copper-Rich Alloys. (Dichte und Härte bei kupferreichen Legierungen.) G. KREBS. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, May 1, 1932, page 186.

The effect of various cooling velocities on density and hardness of brasses and bronzes is considered. The effect of occluded oxygen on structure and mechanical properties is pointed out. GN (12b)

Ingot Molds. (Lingotieres a Jets.) DELCROISETTE. *Revue de Fonderie Moderne*, Vol. 26, June 10, 1932, pages 183-186.

The different forms of ingot molds, in one piece or composed of 2 or more, and their respective advantages are discussed. As the quality of the casting often depends on the kind of mold their composition is of importance; for small ingot molds, the addition of 30% of hematitic cast scrap is recommended, for larger ones only 25%. Several examples of 2-part and water-cooled molds are illustrated. Ha (12b)

Rolling (12c)

Modern Improvements in Refined Iron and Rod Mills. (Neuere Entwicklung der Feineisen-und Drahtwalzwerke.) ALBERT NÖLL. *Stahl und Eisen*, Vol. 52, Mar. 31, 1932, pages 305-309; Apr. 21, 1932, pages 381-389.

1 Report 93 of Rolling Mill Committee of Verein deutscher Eisenhüttenleute. After general description of refined iron mill roll and eccentric cooling beds, pits, improvements in shears, etc., author shows effect of temperature variation at beginning and end of a rod on physical properties of material. Elastic limit and tensile strength of trailing end of rod are higher, and elongation lower than leading end. Trailing end shows finer crystal structure. Diagrammatic sketches show continuous mill stands. New semi-continuous mill stand and improved old-type stands of Vereinigte Stahlwerke, A.-G., Niederrheinische Hütte, Duisburg-Hochfeld are detailed with illustrations. DTR (12c)

Reducing and Widening of Tubes. (Reduzieren und Aufweiten von Röhren.) F. OWESNEY. *Die Röhrenindustrie*, Vol. 24, Apr. 23, 1931, pages 97-98.

2 The advantages and disadvantages of rolling and drawing processes are compared with reference to the manufacture of tubes. During the drawing of tubes a necking is liable to occur and a new method for overcoming this trouble is sketched. EF (12c)

The Production Capacity of Merchant Mills. U. A. PETERS. *Rolling Mill Journal*, Vol. 5, May 1931, pages 347-349.

3 The author believes that the total amount of reduction from billet to final section should be considered in making capacity comparisons between mills of different types. He furnishes a table showing the number of passes and the elongations obtained in rolling various sections such as channels, I-beams, angles, etc. He gives a short discussion of the influence of the "lead," height of material, diameter of roll, temperature and speed of roll upon the flow of metals in rolling. JN (12c)

A 325 mm. Steel Rolling Mill. (Train à fers de 325 m/m de diamètre.) J. SCHOEPP. *Revue de Métallurgie*, Vol. 29, Apr. 1932, pages 221-227.

4 Structural features of a high efficiency merchant mill built for Societe anonyme des Forges de la Providence. JDG (12c)

Gray-Iron Rolls from the Basic Open-Hearth Furnace. (Graugusswalzen aus dem basischen Siemens-Martin-Ofen.) KURT HOFFMANN. *Die Giesserei*, Vol. 19, Mar. 4, 1932, pages 88-90.

5 Due to prevailing conditions it had become necessary for economic operation of an open-hearth furnace to make use of it also for producing cast-Fe which was mainly to be used for casting rolls. The charge was made up of roll scrap, ingot mold scrap, rails, pig iron and 10 to 12% ferrosilicon. The results were very satisfactory, the hearth, however, had to be repaired after each heat as it was strongly attacked by the high manganese oxide content. The rolls were cast in chill molds with a thin lining of clay and showed a dense fine grain. Their Brinell hardness was 250, and they had a very high wearing resistance which made them specially suitable as rolls in a roughing mill for a wire mill. Ha (12c)

American Rolling Mill Construction. (Eindrücke im amerikanischen Walzwerksbau.) A. KOEGEL. *Stahlbautechnik*, Supplement to *Montanistische Rundschau*, Vol. 24, Mar. 16, 1932, pages 3-5.

6 A review of the original article which appeared in *Stahl und Eisen*, Vol. 51, Nov. 26, 1931. See *Metals & Alloys*, Vol. 3, July 1932, page MA 219. GN (12c)

Electroroller With Stationary Axle. (Die Elektrorolle mit feststehender Achse.) *Demag Nachrichten*, Vol. 6, Mar. 1932, pages 1-5.

The article shows the latest development in construction of electro-rollers to be used in cooling beds of rolling mills. The advantages which individually driven electro-rollers offer in comparison with the drive by bevel gears are pointed out. The article is supplemented by many illustrations. GN (12c)

7 **Mills for Rolling Thin Sheets.** *Iron & Coal Trades Review*, Vol. 124, Jan. 8, 1932, pages 35-36.

A few German installations of 2-high and 3-high finishing stands and with lever doubler for mild steel and automatic doubler for hard steel sheets and a continuous cold mill are described. See "Improvements in Sheet Mills," *Metals & Alloys*, Vol. 3, May 1932, page MA 136. Ha (12c)

Repair of the Foundation of a Large Rolling Mill. (Eine aussergewöhnliche Leistung bei der Grundreparatur einer grossen Walzenstrasse.) *Demag Nachrichten*, Vol. 6, Mar. 1932, pages 5-9.

8 Description of the modernization of the Grey beam mill at Differdingen, Alsace-Lorraine, which was the first to roll Grey beams in Europe. GN (12c)

Rolling & Forging (12c-d)

Observations in the Forging and Rolling of Ledeburite Chromium Steels. (Beobachtung beim Schmieden und Walzen von ledeburitishen Chromstählen.) WERNER ZIELER. *Stahl und Eisen*, Vol. 52, Jan. 14, 1932, pages 38-42.

Includes 18 diagrams. In the forging and rolling of steel containing approximately 1% C and 14% Cr, such as is used in making non-rusting razor blades, difficulties arise due to 9 cracks. The tests show that the cause for these cracks may be due to the ledeburite structure component, the cast structure of which may be destroyed merely by extensive forging work. Efficient improvement in the cast structure of this steel could not be gotten in the annealing or heat treatment; however some improvement could be made after 60 hours annealing, provided the ledeburite nucleus was sufficiently destroyed in the forging operation. The working of ledeburite chromium steels should be done as much as possible below 1150° C. because this is the fusion temperature of the ledeburite eutectic and it forms after a probable destruction of the cast structure. This new formation 10 depends upon the period of time in which the steel is kept approximately at 1150° C. as well as upon the form in which the ledeburite exists. In turn, the form of ledeburite depends upon the kind of working which the steel is given. Rolling is the principal difficulty which yields deep cracks. DTR (12c-d)

Forging (12d)

Pressing and Stamping with the Drop Hammer. (Das Pressen und Prägen mit dem Fallhammer.) C. Züblin. *Die Werkzeugmaschine,* Vol. 36, June 30, 1932, pages 215-219.

The paper compares the various methods of processing articles in mass production. The fundamental differences, mode of operation, advantages and disadvantages of hydraulic presses, knee lever presses, friction presses and drop hammers are discussed. The practical use of each type is described. GN (12d)

Hot Pressings of Brass. J. D. Speakman. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 97-100.

The advantages of hot pressing of brass over castings are listed. A description of the operations involved and the presses employed is given. PRK (12d)

Gas Fired Furnaces Used in Heat Treating and Forging Stainless Steel. J. B. Nealey. *Fuels & Furnaces,* Vol. 9, Dec. 1931, pages 1365-1368, 1390; *Heat Treating & Forging,* Vol. 18, Feb. 1932, pages 129-131.

Describes practice and equipment of the Western forge plant of the General Metals Corporation, Los Angeles, Calif. See *Metals & Alloys,* Vol. 3, Sept. 1932, page MA 275. MS (12d)

Steel Plant Forge Shop. J. R. Miller. *Heat Treating & Forging,* Vol. 18, Apr. 1932, pages 235-236.

Discusses the size, equipment, capacity and location of a centralized steel plant forge shop employed chiefly for plant maintenance. Assumes that plant has an annual capacity of 2,500,000 tons of ingots. Forge shop will require 10,000 to 12,000 ft.^{2} floor space. It should have a 3000 lb. hammer, a 11,000 lb. hammer, two 600 lb. hammers, 10-12 hand forges, a 2″ forging machine, a 3″ forging machine, and 2 heat treating furnaces 6 ft. x 10 ft. and 4 ft. x 8 ft. hearth size. The shop will have an annual capacity of 2000 tons, while the average yearly demand will be about 800 tons. MS (12d)

Development of Hammer Boards. Harold G. Irwin. *Heat Treating & Forging,* Vol. 18, June 1932, pages 365-366.

Experience has shown that a solid maple board gives the best service. Northwestern Pennsylvania rock or hard maple has been found to be especially adaptable for hammer boards. Author's firm has developed a treated board ("Silveroc") which will not warp when subjected to atmospheric changes and has a quicker pick-up in the rolls. It is unnecessary to burn the boards or to use fire-clay. Coating will not fuse at 450° F. MS (12d)

Modern Drop Forging. (Modernes Gesenkschmieden.) H. Kaessberg. *Maschinenbau,* Vol. 11, Jan. 21, 1932, pages 29-32; Feb. 4, 1932, pages 52-55.

Discusses standardization, labor saving, etc. for the drop forging plant. Gives new methods for an increase in quality with a simultaneous reduction in costs. Further specialization is predicted as the necessary step to be taken to that end. RV (12d)

Heating Steel for Forging. N. L. Deuble. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 19-23, 30-31.

Discusses effects of time, temperature, composition of the steel and size of the piece with regard to heating of steel in ordinary box-type furnaces. Plain C steels up to 0.50 C and low alloyed steels up to 0.40 C can be heated quite rapidly in sizes under 5″ square. From 5″ up to 12″ square they should be preheated before charging into a forge furnace at heat. Over this size they should be charged cold and brought up gradually. The cooling of forgings over 5″ square, equivalent cross-section, should be controlled. Sensitive steels, comprising the higher alloy, stainless, and heat-resisting steels, should be preheated to 1400°-1600° F. before charging into the hot furnace. Large sizes should be charged into a cold furnace and brought up gradually. It is important that the forgings be cooled uniformly and slowly, preferably in a furnace. Large sizes must be furnace cooled. Finally, one must be governed by his own experience. Tabulates results of short-time hot tensile tests of the following steels: (1) 0.04% C, 0.25% Mn. 0.50% Cu and 0.08% Mo; (2) 0.15% C, 0.40% Mn, 25% Cr, 15% Ni and 2% W; and (3) S.A.E. 3140. MS (12d)

Machinery (12g)

Machining with Greatest Smoothness by Diamonds. (Feinstbearbeitung durch den Diamanten.) P. Grodzinski. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, June 19, 1932, page 329.

Discussion of the advantages which the diamond offers for machining surfaces with greatest smoothness. Its application in the optical and automotive industry is pointed out. GN (12g)

New Machine Tools Inspire Revisions in Marketing. *Steel,* Vol. 90, Jan. 4, 1932, pages 164-165.

The revolutionary developments in both machine design and marketing methods started by the machine tool industry in 1930 have been continued on through 1931. The year has witnessed a more general adoption of welded steel frames, antifriction bearings and hydraulic change gear devices, improvements in high speed tool steels and a wider use of cemented-carbide cutting materials. Other developments are the introduction of multiple motor drives, the wider use of conveyor handling methods, hydraulic feeds and electrical controls, the reduction of noises and shock to machinery through the use of rubber cushions, specially designed shock absorbing mountings and better workmanship, and the attainment of more flexible control of heavy machinery through the use of automatic and remote control systems. JN (12g)

A New Original Method for Producing Tools of Irregular Shapes. (Ein originelles, neues Verfahren zur Herstellung von Werkzeugen unregelmässiger Formen.) Schlippe. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 8, Jan. 10, 1932, pages 1-4.

Treats of a new grinding method in which it is not necessary to force the piece into a specially constructed shaft to shape it. The machine used needs an expert operator, but it is simple and not expensive. It is very efficient and has a long life, and can be used for many different shapes. MAB (12g)

Drawing & Stamping (12h)

Making Pressed Steel Bodies. *Automobile Engineer,* Vol. 21, Nov. 1931, pages 511-517.

Survey of methods and materials used by the Pressed Steel Company of Great Britain in the manufacture of automobile bodies. Most of the material bought is sheet steel and all of it is tested for ductility and the character of the surface. Steels for body panels should contain: C, under 12%; Mn, 0.3-0.5%; S, under 0.045%; P, under 0.045%; Si, a trace. Describes physical tests. Properties should be: ultimate strength, 46,000-52,000 lbs./in.^{2}; yield point, 30,000-35,000 lbs./in.^{2}; percentage elongation in 8 ins., over 26%. Describes handling equipment and welding practice. RHP (12h)

Pickling (12i)

Modern Pickling—Results Achieved with Acids and Inhibitors Reviewed. O. L. Thomas. *Iron Age,* Vol. 129, Mar. 3, 1932, page 548.

Abstract of paper read before the Hartford, Conn., chapter of the American Society for Steel Treating. Acids commonly used in pickling are: H_2SO_4, HF and HNO_3. Metal parts in pickling room should be covered with pitch or acid resistant paint. Acid consumption varies with area pickled and thickness of scale. Agitation of bath is essential. Gives solutions for high C steels. Cites advantages of using inhibitors. VSP (12i)

Pickling Additions and Removal of Waste Water in Metal Pickling Plants. (Beizzusätze und Abwässerbeseitigung in Metallbeizereien.) Freitag. *Oberflächentechnik,* Vol. 9, May 24, 1932, pages 99-100.

Additions to the pickling solution are mainly for the purpose of removing in the pickling process not only the oxides (scale) from the metal surface without attacking the latter, but also to prevent the so-called pickling brittleness which consists in an occlusion (retaining) of the hydrogen by the metal. These additions are mostly of unknown compositions. The patent literature is briefly reviewed and the possibilities of recuperating metal salts or other valuable constituents from the plating solutions are discussed and described. Ha (12i)

Polishing & Grinding (12l)

Automatic Internal Grinder. H. L. Blood. *Transactions American Society of Mechanical Engineers,* Vol. 54, Feb. 15, 1932, Machine Shop Practice, pages 1-7.

Methods and machines which positively determine the size of the hole and require no gaging on the part of the operator are described. Ha (12l)

The Grinding of the Cut-out Parts of Locomotive Frames on the Stationary Schmaltz Grinding Machine. (Das Schleifen der Lokomotiv- Rahmenausschnitte auf der stationären Schmaltz'schen Rahmenbackenschleifmaschine.) Rüter. *Glasers Annalen,* Vol. 11, Aug. 1, 1932, pages 19-23.

Description of installation and operation of the Schmaltz machine for grinding the cheek-pieces of locomotive frames in the repair shop at Schwerte, Germany. The instruments for adjusting the frames are described. Experiences in grinding materials used are reported. GN (12l)

Lap Shaft Bearings and Pins. *Abrasive Industry,* Vol. 13, Feb. 1932, pages 29-30.

A new crankshaft lapping machine has been developed for lapping simultaneously the pin and bearings of automotive crankshafts. The shaft to be lapped is rotated between a live headstock and a floating footstock center. The lapping arms, one of which is required for each pin and bearing, are equipped with telescoping reels, each carrying a roll of abrasive paper. When a lapping arm is removed from a pin or bearing these reels are indexed automatically, thus presenting a fresh, unused surface to each pin and bearing lapped. WAT (12l)

Coloring (12m)

Alumilite Process. R. W. Pettit. *Monthly Review, American Electroplaters Society,* Vol. 19, Apr. 1932, pages 6-7.

Aluminum articles after cleaning in a hot alkaline bath are anodically treated in a bath (composition not given) at 15 amp./ft.^{2}, 12 volts, 72-80° F. for 15-45 minutes. Cooling coil and air agitation used. After the anodic treatment, the articles are immersed in a color bath for 3-10 minutes at 180° F. LCP (12m)

Black Oxidized Finishing. L. C. Hudgins & H. A. Cameron. *Monthly Review, American Electroplaters Society,* Vol. 19, Mar. 1932, pages 17-20.

Paper before Rochester Convention, July 1931. 2 commercially successful processes are described: (1) black color on brass, using an air-agitated bath containing 2.67 oz./gal. $CuCO_3Cu(OH)_2$ and 42.7 oz./gal. 28% NH_3, 2-4 min. immersion; (2) black color on Cu, using a solution of K_2S, 2 oz./gal. at 80° F. LCP (12m)

Sand Blasting (12n)

A Laboratory Test for the Hardness of Sandblast Sand. Emerson P. Poste. *Journal American Ceramic Society,* Vol. 15, May 1932, pages 110-113.

The change in fineness of a sand produced by grinding a 200-gram sample in a standard jar mill for 1 hour is taken as an indication of its durability in sandblasting. Results of laboratory tests on certain sands are compared with the change in fineness of these sands in actual sandblasting operation. The test is applied to sands known to be of inferior quality. Discussion of the results is based on the assumption that sand finer than 40-mesh has but little sandblasting value. WAT (12n)

Spinning (12p)

Spinning a Monel Metal Piston. Harry Shaw. *American Machinist,* Vol. 76, Jan. 28, 1932, page 129.

Brief description and line illustrations of the operation. RHP (12p)

CHEMICAL ANALYSIS (14)

The Electrometric Titration of Uranium with Ceric Sulfate. DWIGHT T. EWING & MABEL WILSON. *Journal American Chemical Society*, Vol. 53, June 1931, pages 2105-2110.

When a hot acid solution of uranium sulphate is reduced in a Jones reductor and is titrated in an atmosphere of nitrogen with ceric sulphate as an oxidizing agent, 2 end points are obtained. The amount of uranium oxidized between the 2 end points corresponds exactly to the amount of uranium present. 2% H_2SO_4 gave the best results. MEH (14)

Colorimetric Determination of Molybdenum. L. H. JAMES. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 4, Jan. 15, 1932, pages 89-90.

This is essentially the method of Maag and McCollam. Butyl acetate is used in place of ether for extracting the brown coloration produced by the formation of molybdenum thiocyanate, and perchloric acid replaces the H_2SO_4. MEH (14)

The Simultaneous Determination of Hg and Halogens in Organic Compounds. (Determinazione contemporanea di mercurio e alogeni nelle sostanze organiche.) G. ILLARI. *Annali di chimica applicata*, Vol. 22, May 1932, pages 261-272.

The compound is oxidized electrolytically, using HNO_3 (1.4) with Pt electrodes, and a current of 125 v and 0.5 amps. 1 to 4 hours are required. The Hg is then determined by the usual electrolytic method, in the same cell. The evolved gases are absorbed in KOH, so that halogen may be determined by combining this solution with the liquid remaining after the electrolysis. AWC (14)

Inaccuracy in the Determination of Mercury by Direct Precipitation as Mercuric Sulfide from Acid Solution. E. P. FENIMORE & E. C. WAGNER. *Journal American Chemical Society*, Vol. 53, July 1931, pages 2453-2456.

It is claimed that an impure product is obtained when Hg is precipitated directly as the sulphide. Causes are discussed. Volhard's procedure is accurate when applied to solutions which contain the Hg salt and not much else, but presence of salts in quantity, and of iodide especially, leads also to higher results. MEH (14)

A Simple Separation of Molybdenum and Rhenium. (Eine einfache Trennung von Molybdän und Rhenium.) W. GEILMANN & F. WEIBKE. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 199, No. 4, 1931, pages 347-352.

A quantitative separation can easily be made by 8-oxychinoline, the Re is then determined by nitron in the filtrate of oxychinoline precipitate. Small amounts of Re can be separated from the principal quantity of Mo by distillation; from the distillate Re is then determined as described before. Ha (14)

Method for Electrolytic Extraction of MnO, MnS, FeS and SiO_2 Inclusions from Plain Carbon Steels. G. R. FITTERER. *Transactions of the American Institute of Mining & Metallurgical Engineers*, Vol. 95, 1931, pages 196-218.

Includes discussion. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 316. (14)

The Preparation of Pure Electrolytic Nickel. Part 3. COLIN G. FINK & F. A. ROHRMAN. *Transactions Electrochemical Society*, Vol. 59, 1931, pages 359-369.

Includes discussion. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 184. (14)

Determination of Tin in Ferro-Tungsten and Tungsten Ores. (Zinnbestimmung in Ferrowolfram und Wolframerzen.) KARL KIEFER. *Zeitschrift für analytische Chemie*, Vol. 88, No. 7/8, 1932, pages 243-248.

The author points to the lack of a convenient method for routine determination of Sn in Fe-W or W ores which almost always carry Sn, and describes a new precipitation method for W by depositing it from an acid solution by oxidation from WO_2 to WO_3. Ha (14)

The Emission Spectrum Analysis and Its Practical Application. (Die Emissionsspektralanalyse und ihre praktische Anwendung.) H. LUCAS. *Zeiss Nachrichten*, July 1932, pages 19-25.

The paper first discusses the advantages of spectrum analysis as contrasted with chemical analysis. 3 references. GN (14)

The Titration of Copper with Sodium Sulphide and the Determination of Small Quantities of Dissolved Sulphides. (Ueber die Titrierung des Kupfers mit Schwefelnatrium und über die Aufsuchung kleiner Mengen gelöster Sulfide.) A. BORNTRAEGER. *Zeitschrift für analytische Chemie*, Vol. 87, No. 9/10, 1932, pages 342-352.

The procedure is fully described and comparisons with other methods show that for practical use this method is still the most convenient and accurate. Ha (14)

Quantitative Determination of Nickel and Cobalt Simultaneously. (Quantitative Mikrobestimmung von Nickel und Kobalt nebeneinander.) A. OKAC. *Zeitschrift für analytische Chemie*, Vol. 88, No. 11/12, 1932, pages 431-433.

Since the potential and other electrolytic conditions for the electrodeposition of Ni and Co are very closely similar both metals can be precipitated simultaneously on the cathode from a solution in suitable form. The test and the method used is described in detail; current densities of 0.5-1.0 amp./dm.^{2} were used and both metals were precipitated on a Pt wire cathode as a bright, well adhering metal. Ha (14)

The Analysis of Red Bronze and Brass. (Die Analyse von Rotguss und Messing.) O. NIEZOLDI. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, May 1, 1932, pages 186-187.

Description of common methods of analysis for the above alloys. GN (14)

The Determination of Small Amounts of Antimony in Copper and Its Alloys. (Zur Bestimmung kleiner Antimonmengen im Kupfer und seinen Legierungen.) W. BOEHM & W. RAETSCH. *Zeitschrift für analytische Chemie*, Vol. 88, No. 9/10, 1932, pages 321-324.

Sb in Cu alloys can usually be readily determined by precipitation with ammonia in the presence of the iron-salt after previous dissolution with HNO_3 so that the more time-consuming method of Blumenthal can be avoided. Ha (14)

Molecular Spectra and Spectroscopic Analysis. II. Identification of La. (Spettri molecolari e analisi spettroscopico. II. Sulla ricerca del La.) G. PICCARDI & A. SBERNA. *Atti della Reale Accademia dei Lincei*, Vol. 15, Jan. 3, 1932, pages 83-88.

By utilizing a molecular spectrum, instead of the atomic, it is possible to identify 0.01% of La even in the presence of Pr and other rare earths. This is possible because of the simpler spectrum obtained from the molecule as compared to the atom. AWC (14)

The Determination of Bismuth as Metal. (Zur Bestimmung des Wismuts als Metall.) E. RUPP & G. HAMANN. *Zeitschrift für analytische Chemie*, Vol. 87, No. 1/2, pages 32-35.

A modified gravimetric determination of Bi metal according to the method of Vanino is described in detail. This method gives more exact results. Ha (14)

The Determination of Iron in Aluminum. (Sulla determinazione del ferro nell'alluminio.) L. SZEGO. *Giornale di chimica industriale ed applicata*, Vol. 14, May 1932, pages 226-228.

To 2 g. of Al turnings, 25 cc. of water is added, and then successive portions of 10% NaOH, warming towards the end to obtain complete solution of the metal. Filter and wash residue with water. Dissolve the residue with about 20 cc. HCl (1:10) to dissolve the Fe and Ti. That Ti dissolves at this stage indicated that it occurs alloyed to Fe rather than Al. The Fe is then reduced with $SnCl_2$ and the determination carried out according to the Zimmerman-Reinhardt method. The Fe may also be determined iodimetrically, but the oxidation method is shorter. AWC (14)

A Rapid Method for the Determination of Silicon in Silicon Steel, Pig Iron and Cast Iron. (Eine Schnellmethode zur Bestimmung des Siliziums in Siliziumstahl, Roh-und Gusseisen.) OTTO NIEZOLDI. *Chemiker-Zeitung*, Vol. 56, May 7, 1932, pages 363-364.

7 references. An extensive trial of 5 methods was made and the following was found to be the most rapid and accurate: To a 1 g. sample in a 400 cc. beaker add 30 cc. HCl, sp. gr. 1.19, cover ,and heat over an asbestos mat over the full flame of a Bunsen burner. When the sample is in solution add 15 cc. dilute H_2SO_4, remove the cover and heat to fumes. Cool, dilute, add 5-10 cc. conc. HCl and dilute to 100 cc. with H_2O. Filter and wash 6 times. Ignite and weigh SiO_2. CEM (14)

The Determination and Separation of Rare Metals from Other Metals. (XX) The Determination of Iridium and Its Separation from Platinum and Other Metals. (Die Bestimmung und Trennung seltener Metalle von anderen Metallen. (XX) Die Bestimmung des Iridiums und seine Trennung von Platin und anderen Metallen.) LUDWIG MOSER & HEINZ HACKHOFER. *Monatshefte für Chemie*, Vol. 59, Jan. 1932, pages 44-60.

51 references. *Ir from Pt.* To the weakly acid solution of H_2PtCl_6 and $NaIrCl_6$ in 200 to 400 cc. add 1.5 to 2 g. $NaBrO_3$ and heat to 60° C. Add a slight excess of 1:10 NaBr solution and heat to boiling to precipitate greenish black $IrO_2 .X H_2O$. Cover with a glass containing a hole and boil to expel Br. The precipitation is complete when additions of $NaBrO_3$, NaBr solution produce no Br odor and no cloud. Filter and wash with hot NH_4NO_3 solution. Test filtrate by evaporating down. If a skin forms filter off and combine with first precipitate. Dry at 110° C. and heat at 160°-180° C. in a stream of H_2, cool, and ignite in a muffle furnace. If this procedure is not followed, IrO_2 is liable to explode. Then ignite the residue 15 minutes in a stream of H_2. Leach the residue several times in hot weak HNO_3 to separate from Na ions, filter, wash, dry, and ignite as before. Weigh Ir. To the filtrate add HNO_3, boil to expel Br and add $NH_4C_2H_3O_2$ and hydrazine chlorohydate solutions. Reduce and weigh Pt. *Ir from Au.* Use the same procedure as in separating from Pt, except dilute the solution to 600 cc. as $KAuCl_4$ is harder to wash out. Wash the precipitate several times with hot H_2O by decantation. Determine Au in the filtrate with hydrazine. *Ir from Pd.* Precipitate IrO_2 with $NaBrO_3$, NaBr solution as before. The precipitate contains some Pd. Filter and wash with hot H_2O. Evaporate the filtrate and filter again. Dry the precipitates at 110° C., heat in H_2 for 20 minutes at 170°-180° C., ignite, and heat again in H_2. Cool and fill the crucible one-half with 1:1 aqua regia, warm, and pour the solution into a beaker. Repeat this treatment 3 or 4 times. Filter and wash with hot weak HNO_3. Dry, heat in H_2 and ignite. Weigh Ir. Evaporate both filtrates to dryness. Dissolve the residue in hot H_2O and a few drops HCl. Add $NH_4C_2H_3O_2$ and hydrazine chlorohydrate solutions, boil, filter and wash with hot H_2O. Dry the precipitate, ignite in H_2, cool in CO_2 and weigh Pd. Wash again with hot H_2O to remove Cl ions. *Ir from Cu.* Add $NaBrO_3$, NaBr to the solution and allow the precipitate to settle. Filter and wash with hot H_2O. Evaporate the filtrate to 1/3 and add more $NaBrO_3$, NaBr. Filter, wash and heat the combined precipitates ½ hour in H_2 at 170° C. Cool and add 7% HNO_3 and heat on water bath. Decant and repeat the treatment, during which the paper decomposes. Dilute, filter and wash with hot water. Heat the residue at 170° C. in H_2, cool, ignite first in a covered, then in an open crucible. Cool and weigh Ir. Add HNO_3 to the filtrate, evaporate to fumes with H_2SO_4 and electrolyze Cu. *Ir from Fe.* To the weakly acid solution containing Na_2IrCl_6 and $FeCl_3$ add an excess of oxalic acid and boil gently until the reddish brown color of $IrCl_6$ has disappeared and the solution turns yellow. Pass H_2S into the hot solution, then add an excess of NH_4OH. Filter and wash with water containing $(NH_4)_2S$ and $(NH_4)_2SO_3$. Dissolve the precipitate in dilute HNO_3 and repeat the precipitation. Ignite the FeS in a stream of H_2 and H_2S and weigh as FeS. Evaporate the combined filtrates to dryness, add $(NH_4)_2S$, evaporate and repeat. To the residue add H_2O and NH_4NO_3 and filter. The filtrate must be colorless, not yellow. Dry the residue of Ir_2S_3, heat slowly in a covered crucible to red heat, cool to 100° C., uncover and ignite in H_2. Wash with H_2O, ignite in H_2 and weigh Ir. CEM (14)

Rapid Method for Determination of Sulfur in Brass and Bronze. J. O. COONEY. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 4, Jan. 15, 1932, page 33. Method consists in dissolving sample in cupric ammonium chloride and precipitating sulphur as sulphide, filtering, oxidizing to sulphate and precipitating as barium sulphate. MEH (14)

Mine Production of Gold, Silver, Copper, Lead and Zinc in Oregon in 1931, by Counties. VICTOR C. HEIKES. *United States Bureau of Mines, Mineral Market Reports.* No. M.M.S. 132, July 14, 1932, 1 page.

Oregon's total productions for 1931 (and 1930) were: Au 15,350.10 oz. (14,401.34 oz.); Ag 7,254 oz. (9,000 oz.); Cu 1,700 lbs. (176,300 lbs.); Pb 3.497 lbs. (9,113 lbs.); Zn ..... (12,528 lbs.); total value $319,703 ($325,143). AHE (16)

Mine Production of Gold, Silver, Copper, Lead and Zinc in New Mexico in 1931, by Counties. CHAS. W. HENDERSON. *United States Bureau of Mines, Mineral Market Report* No. M.M.S. 147, Aug. 23, 1932, 2 pages.

Production of Au, Ag, Cu, Pb and Zn in New Mexico in 1931 (and in 1930) was Au $644,160 ($669,156), Ag 1,041,859 oz. (1,107,335 oz.), Cu 61,503,100 lbs. (65,150,000 lbs.), Pb 22,537,000 lbs. (20,756,900 lbs.), Zn 55,732,000 (65,529,000 lbs.), and value $9,494,766 ($13,748,217). AHE (16)

Mine Production of Gold, Silver, Copper, Lead, and Zinc in Nevada in 1931, by Counties. VICTOR C. HEIKES. *United States Bureau of Mines, Mineral Market Reports.* No. M.M.S. 133, July 15, 1932, 1 page.

Nevada's total productions for 1931 (and 1930) were: Au 142,293.76 oz. (149,064.47 oz.); Ag 2,562,071 oz. (4,219,832 oz.); Cu 72,634,497 lbs. (109,203,512 lbs.); Pb 15,860,634 lbs. (23,058,381 lbs.); Zn 20,861,348 lbs. (29,168,117 lbs.); total value $11,673,787 ($21,455,517). AHE (16)

Production of Gold, Silver, Copper, Lead, and Zinc in California in 1931, by Counties. VICTOR C. HEIKES. *United States Bureau of Mines, Mineral Market Reports.* No. M.M.S. 124, July 20, 1932, 2 pages.

Total production of Au, Ag, Cu, Pb and Zn in California in 1931 (and in 1930) was Au 523,135.09 oz. (457,199.98 oz.), Ag 867,818 oz. (1,622,803 oz.), Cu 12,931,995 lbs. (27,285,272 lbs.), Pb 3,757,256 lbs. (3,559,564 lbs.), Zn 159,865 lbs. and total value $12,387,734 ($13,801,004). AHE (16)

Tungsten in 1930. FRANK L. HESS. *Mineral Resources of the United States, United States Bureau of Mines,* 1930, Part 1, Jan. 9, 1932. pages 179-207.

Sales of W concentrates produced in the United States again dropped in 1930, amounting to an equivalent of 702 short tons carrying 60% WO_3, as compared with 830 tons in 1929. 58 references appearing in 1930 are given. AHE (16)

Canadian Facilities for Handling British Steel. T. M. HUTCHISON. *Iron & Steel of Canada,* Vol. 15, May 1932, pages 57-58.

An article emphasizing the prompt mill service of certain Scottish steel mills and its possible effect upon the economics of the steel trade in Canada. OWE (16)

Bauxite and Aluminum in 1930. C. E. JULIHN. *Mineral Resources of the United States, United States Bureau of Mines,* 1930, Part 1, Dec. 14, 1931, pages 151-178.

World production of Al in 1930 decreased only about 3% from 1929, while bauxite production was off 15 to 20%. In the U. S. Al production (114,518 short tons) increased 2% in quantity and decreased 2% in value. Domestic bauxite output (330,612 long tons) decreased 9.6% (15% in value) but supplies increased nearly 4% as imports increased and exports decreased. Consumption of Al in automobiles and aircraft decreased, but its use for truck and bus bodies, strong Al alloys, electrical conductors and Al paint increased. 60 references. AHE (16)

Mine Production of Gold, Silver, Copper, Lead and Zinc in Washington in 1931, by Counties. C. N. GERRY. *United States Bureau of Mines, Mineral Market Reports.* No. M.M.S. 134, July 15, 1932, 1 page.

Washington's total productions for 1931 (and 1930) were: Au 2,904.19 oz. (4,244.81 oz.); Ag 22,410 oz. (32,816 oz.); Cu 202,503 lbs. (1,206,438 lbs.); Pb 2,771,116 lbs. (1,152,585 lbs.); Zn 9,947,495 lbs. (703,782 lbs.); total value $565,498 ($348,630). AHE (16)

Need for Reducing Materials Handling Costs is Impetus to Mechanization. *Steel.* Vol. 90, Jan. 4, 1932, page 167.

The use of mechanical conveying equipment expedites deliveries, enlarges the capacity of the plant, and reduces production costs. During 1931 car dumpers, cranes, hoists, trucks, tractors, and all types of conveyors have been redesigned and improved. The use of antifriction bearings, automatic control, simpler designs, and better and lighter materials has resulted in more exact speeds and in better coördination. Newer applications of mechanization are seen in the manufacture of spiral welded pipe, the fabrication of structural shapes, and the handling of sheets, plates and coils. JN (16)

Cadmium Industry in 1931—Summary. H. M. MEYER. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 112, May 24, 1932, 1 page.

Production of metallic Cd in 1931 amounted to 1,050,529 lbs., 38% of 1930 output and 23% of the 1930 value. Sales decreased only 7% in quantity but 44% in value. AHE (16)

The British Steel Industry. H. STANLEY JEVONS. Isaac Pitman & Sons, New York, 1932. Paper, 5½ x 8½ inches, 31 pages. Price 1 sh.

The author discusses the present status of the British Steel Industry and suggests a remedy. (16)-B-

Copper in 1931. EDWARD HODGE ROBIE. *Mining Journal,* Annual Review No., Feb. 13, 1932, page 4.

Cu had its worst year in 1931. Producers stocks increased to about 800,000 tons. AHE (16)

The Production of Gold and Other Metals. *Journal Society of Chemical Industry,* Vol. 51, Apr. 29, 1932, page 374.

The following data on the production of metals, taken from a speech delivered by Sir Robert Hadfield of Hadfield's Ltd. at the annual meeting on Mar. 31, are graphically presented.

Metal	Period	Output in long tons	Value
Gold	1493-1931	32,700	£ 5,100 millions
Silver	1493-1931	397,000	2,900
Copper	1800-1931	39,500,000	2,200
Iron	1800-1931	2,895,000,000	16,000
Coal	1800-1931	52,000,000,000	39,000

If Gold Should Cease to be "Gold." STEPHEN LEACOCK. *Canadian Mining & Metallurgical Bulletin* No. 244, Aug. 1932, pages 430-439.

The effect of universal demonetization of Au would be to destroy the value of Au as a commodity. AHE (16)

1 **Silver Consumption in the Arts and Industries of the United States in 1930 and 1931.** CHARLES WHITE MERRILL. *United States Bureau of Mines, Information Circular* 6647, July 1932, 7 pages.

The total consumption of Ag in the arts and industries in 1931 was 23,578,955 oz. (23,981,164 oz. in 1930; 28,601,311 oz. in 1929; 25,826,554 oz. in 1928). The ratio of scrap returned to smelters and refiners to total turnover has increased progressively from 30.6% in 1928 to 33.1% in 1931. Percentage consumption in 1931 by various industries was: Sterling Ag 37.4%; photographic 27.9%; electroplating 9.8%; jewelry, optical goods and novelties 8.8%; chemical 6.2%; industrial (including solders) 5.2%; dental 2.8%; miscellaneous 1.5%; and loss 0.4%. Comparative figures for 1928, 1929 and 1930 are given. Sterling Ag industry used only 76% as much Ag in 1930 as in 1929, but showed marked recovery in 1931.

2 AHE (16)

The Iron and Steel Industry in the United States. E. D. MCCALLUM. P. S. King & Son, Ltd., London, 1931. Cloth, 5¾ x 8¾ inches, 33 pages. Price 12s. 6d.

This book permits us to obtain a view of ourselves through the eyes of a foreigner equipped to see truly and report accurately. During 1927-1929 McCallum was in the United States as occupant of a Rockefeller fellowship in social sciences and during this time he gathered the material for his book. To American readers the value of the book will lie not so much in the subject matter, as most of it is well known in the United States and has been covered in domestic publications. The approach of this author and his conclusions, though, are of the greatest interest, furnishing a viewpoint devoid of the patriotic pride almost inseparable from a similar narrative by an American and especially one in the steel industry. The few errors which appear detract little from the value of the work, except as setting up a few misstatements which will cause possible confusion in the future. (16) -B-

By-product Sulphuric Acid at Copper and Zinc Plants in 1931. H. M. MEYER. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 140, Aug. 5, 1932, 1 page.

The output of by-product H_2SO_4 in 1931 (and 1930) at Cu plants was 436,111 tons (651,702 tons) and at Zn plants was 426,618 tons (536,614 tons). At Zn plants 100,956 tons (125,740 tons) of S was used to supplement the roaster gases to produce 381,216 tons (474,092 tons) of H_2SO_4. AHE (16)

British Steel for the Canadian Market. J. L. PIGGOTT. *Iron & Steel of Canada,* Vol. 15, May 1932, pages 56-57.

5 An article by the manager of the British Steel Export Association, in which attention is directed among other things to the policy of British exporters in attempting to provide heavy sections and plates not made in Canada for Canadian users. OWE (16)

The Canadian Copper Industry in 1931. R. E. PHELAN. *Mining & Metallurgy,* Vol. 13, Feb. 1932, pages 94-95.

While 1931 was a most important year in Canadian Cu smelting and refining, due to low prices and inability of the International Nickel Company to market its capacity of Ni, the production of Cu and Ni was less than total installed capacity. VSP (16)

6 **Nickel Resources, Production and Utilization.** E. S. MOORE. *Preprint, American Institute Mining & Metallurgical Engineers,* Feb. 1932, 13 pages.

Canada and New Caledon are the only countries that produce large quantities of Ni. The Sudbury field in Canada is now the principal producer. In 1930 it produced 90% of the world's output. Prior to 1918 the chief use of Ni was in ordnance, but since the War many new uses were developed. The production for 1930 exceeded that of any previous year. The price of electrolytic Ni has been fixed during the past 5 years. JLG (16)

7 **The Tin Industry.** S. HECKSTALL SMITH. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 59-60.

Descriptions are given of the governmental control of 95% of the total world's production of Sn, and of the international Tin Pool which does not sell unless the spot price of tin is £165 a ton. A small export duty on Sn supplies funds for a 5 year program of research and development work. PRK (16)

Future of the Drop Forging Industry. C. H. SMITH. *Heat Treating & Forging,* Vol. 18, Mar. 1932, pages 174-177.

8 Paper presented before the Cleveland chapter, American Society for Steel Treating, Mar. 1932. Discusses the necessity of price stabilization, which is one of the most serious problems facing the drop forging industry. Better knowledge of costs will aid in overcoming the evil of price cutting. Deals with the survey of the industry being made by the U. S. Department of Commerce, importance of trade associations in relation to business, research and safety. MS (16)

A Survey of the Copper Position. E. BALIOL SCOTT. *Mining Journal,* Vol. 177, June 18, 1932, pages 415-416.

The effect of the American tariff on the Cu industry is discussed, together with other features of Cu trade. AHE (16)

9 **Japanese Iron and Steel Industry.** JAMES A. RABBITT. *Steel,* Vol. 90, Mar. 7, 1932, pages 31-34.

The production of pig-Fe in Japan increased 225% and steel 400% between 1920 and 1930. These industries have advanced in direct proportion to the country's general economic growth. The lack of home supplies of coking coal and Fe ore has been overcome by development of deposits in the colonies and by arrangements with Manchuria and the Malay States. Fe ore reserves in Japan are estimated at 40 to 80 million tons, Korea 20 to 30 million tons, and South Manchuria 300 to 750 million tons. The Government, itself, produces about 1/3 of the annual output of pig-Fe and steel. Individual enterprise by private works is encouraged by substantial exemptions from taxes. Production costs are somewhat higher than in the U. S. Fuel costs favor the electric furnace method for the reduction of scrap. The use of alloys has not kept pace with scientific progress. JN (16)

The Engineering Outlook. I. Economic Retrospect and Prospects for 1932. *Engineering,* Vol. 133, Jan. 1, 1932, pages 17-18.

Monthly iron and steel consumption figures are given for the years 1924 to 1931 inclusive. Production index figures are given for the same years using 1924 as the base figure. LFM (16)

Molybdenum Industry in 1931. *Iron & Coal Trades Review,* Vol. 124, Apr. 29, 1932, page 711.

A brief review of the world's production in 1931. 2 American companies, in Colorado and New Mexico, respectively, and 1 Norwegian company produced all but 2%. About 3000 tons of concentrates containing 5,221,000 lbs. of MoS_2 were produced at the mines. Ha (16)

Tin World Statistics 1932. Anglo-Oriental Mining Corp., Ltd., London, 1932. Cloth, 4 x 6¾ inches, 137 pages.

This book contains tabulated statistics on the production, consumption and stocks of tin. Tables show the history of price changes. (16)-B-

Towards Cheaper Steel. Becker Coke Ovens at Scunthorpe: First British Installation to be Heated by Blast Furnace Gas. *Gas World,* Vol. 97, Aug. 6, 1932, Coking Section, pages 14-18; *Gas Journal,* Vol. 199, July 20, 1932, pages 149-153.

In an attempt to reduce operating costs to maintain its existence in the depression and to face foreign competition, the most fruitful field for investigation for the steel-making industry is the more efficient utilization of fuel available in the various processes of Fe and steel manufacture. By the installation of the plant described in the article, the company is able to produce a coke of such strength, uniformity of size, and combustibility that the whole of the production down to ¾" in size can be used in the blast furnaces, and yet less coke is required per ton of pig Fe produced. The coke oven gas produced, of high thermal value, is more efficient in the steelworks than is any other type of fuel. So nice a balance is obtained between the total heat produced and that used in the manufacture of coke, pig Fe and steel, that no fuel of any description is required other than the coal charged into the coke ovens. The reduction effected more than justifies the capital expenditure. The heating system, regenerators, battery control, coke discharging plant, quenching and screening operations, Lodge-Cottrell detarrers, ammonia saturators and acid separators, sulphate drying and bagging and the ammoniacal liquor, tar and acid services are described. MAB (16)

Industrializing Russia. *Metallurgia,* Vol. 6, Aug. 1932, pages 107-110.

Describes construction on Dnieper river. A large Al-reduction plant and steel mill are being constructed near the dam. JLG (16)

How can the Over-production of Arsenic be used? (Wie lässt sich die Überproduktion von Arsen unterbringen?) *Die Metallbörse,* Vol. 22, May 18, 1932, page 627.

The world's production of As is traced from pre-war times till now. Although the consumption increased from 10,000 tons to 50,000 tons since 1913, there is an overproduction since the discovery of large deposits in Sweden in 1926. The American natural resources and production figures are presented and the use of As and As compounds are discussed in full detail. EF (16)

A Survey of the British Iron and Steel Industry 1913-1929 and 1930-31. Wm. A. Bone. *Journal Society of Chemical Industry,* Vol. 51, Apr. 8, 1932, pages 311-315.

Comparison of Fe and steel production in 1913, 1929, and 1930-31 to the effect that an increased tariff would not increase production, that British practice is the more expensive open hearth process as opposed to the basic Bessemer process in use on the Continent and that obsolescent plants should be replaced. VVK (16)

The Metal Year 1931. (Das Metalljahr 1931.) A. Marcus. *Die Metallbörse,* Vol. 22, Jan. 2, 1932, pages 1-2; Jan. 6, 1932, page 20; Jan. 9, 1932, page 36; Jan. 16, 1932, page 68; Jan. 20, 1932; pages 84-85; Jan. 23, 1932, page 100; Jan. 27, 1932, page 116; Feb. 3, 1932, page 149; Feb. 13, 1932, page 196.

In the introduction, the economical changes and events on the world's market, which also affected the metal trade, are summarized with reference to the year 1931. Next the development of the Cu-market is traced, mainly based on information of the American Bureau of Metal Statistics. The domestic Cu consumption as well as the export figures are compiled covering the last decade. The Cu-production and stock in the U. S. A., England and France is graphically presented for the first 9 months of 1931, and the sales in the most important places, London, Hamburg and Berlin, are reviewed. The writer also discusses the developments in the Sn, Pb and Zn market with particular emphasis on production, consumption and prices of the metals. EF (16)

Production of Gold, Silver, Copper, Lead and Zinc in Idaho in 1931, by Counties. C. N. Gerry. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 141, Aug. 9, 1932, 2 pages.

Production of Au, Ag, Cu, Pb and Zn in Idaho in 1931 (and 1930) was: Au 18,361.36 oz. (21,445.7 oz.), Ag 7,220,923 oz. (9,420,639 oz.), Cu 1,144,915 lbs. (3,111,555 lbs.), Pb 198,729,228 lbs. (268,115,963 lbs.), Zn 39,137,212 lbs. (75,298,172 lbs.) and total value $11,418,013 $21,494,867). AHE (16)

Aluminum Industry in 1931—Advance Summary. H. W. Davis. *United States Bureau of Mines, Mineral Market Reports* No. M.M.S. 128, June 29, 1932, 2 pages.

177,544,000 lbs. of new Al valued at $37,284,000 was produced in the U. S. in 1931 (229,035,000 lbs., $50,961,000 in 1930). Imports of Al metal, scrap and alloy were 14,664,195 lbs., a decrease of 42% from 1930. Imports which increased were as follows: plates, sheets, bars, etc. 168,612 lbs. (248%); bronze powder and powdered foil 591,684 lbs. (27%); foil less than 0.006" thick 1,070,119 lbs. (44%); hollow ware 117,649 lbs. (14%). Exports of Al ingots, scrap and alloys were 1,510,688 lbs., an increase of 149% over 1930. Exports of plates, sheets, bars, etc. decreased 81% to 3,190,190 lbs.; exports of tubes, moldings, castings and other shapes were 1,292,400 lbs., 31% less than 1930; the value of table, kitchen, etc. utensils exported decreased 31% and that of other Al manufactures 55%. AHE (16)

Platinum and Allied Metals in 1931—Advance Final Summary. H. W. Davis. *United States Bureau of Mines Mineral Market Reports* No. M.M.S. 129, July 6, 1932, 5 pages.

The Pt refineries of the U. S. in 1931 purchased 446 oz. of crude placer Pt of domestic origin (797 oz. in 1930) and 34,933 oz. of foreign crude Pt (44,765 oz. in 1930). Domestic materials came from Calif. (353 oz.), Alaska (67 oz.), and Ore. (26 oz.),—foreign from Columbia (29,611 oz.), S. Africa (5,299 oz.), Canada (22 oz.) and Russia (1 oz.). Refined Pt metals recovered (new) in 1931 were Pt 31,274 oz., Pd 2,742 oz., Ir 1,732 oz., osmiridium 272 oz., others 185 oz. and total 36,205 oz. (43,502 oz. in 1930), of which 8,393 oz. was from domestic materials, largely Au and Ag refining. Secondary Pt metals recovered in the U. S. were Pt 33,837 oz., Pd 6,331 oz., Ir 1,823 oz., others 1,743 oz. and total 43,734 oz. (47,316 oz. in 1930). In 1931, 91,718 oz. of metallic Pt was imported ($2,589,941), Ir 1,773 oz., osmiridium 4,877 oz., Os 960 oz., Pd 28,070 oz., Rh 1,629 oz., Ru 595 oz. and total 129,622 oz. The consumption by industries in 1930 and 1931, respectively, was as follows: Chemical 13%, 11%; electrical 16%, 26%; dental 23%, 17%; jewelry 43%, 39%; and miscellaneous 5%, 7%. AHE (16)

Recovery of Metals from Secondary Sources in 1931—Advance Summary. J. P. Dunlop. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 146, Aug. 19, 1932, 4 pages.

The value of nonferrous metals recovered from secondary sources ($110,674,600) (as reported to the Bureau of Mines) decreased 43% from 1930; 21% in total quantity. The main decrease was in Cu (value $47,502,000) and brass (value $17,932,000), 50% in value and 27% in quantity. There was a decrease of 9% in secondary Pb reported by smelters treating ore and bullion and a decrease of 22% in output of Pb in alloys reported by smelters treating scrap and drosses (value of both, $17,367,800). Zn recovered by redistillation decreased about 13,200 tons (value + alloys other than brass $3,207,200) and the Zn recovered in scrap brass was less. Detinning plants treated 27,600 tons less clean Sn plate clippings in 1931 than in 1930. About 66% of the recoveries was as $SnCl_4$ (69% in 1930). Prices were too low to treat old Sn-coated containers. Details are given for Cu, Pb, Zn, Sb, Sn and Ni. AHE (16)

Mineral Production of the United States in 1931—Advance Summary. M. B. Clark & E. T. Shuey. *United States Bureau of Mines, Mineral Market Reports,* No. M.M.S. 145, Aug. 19, 1932, 5 pages.

In 1931, the value of mineral products in the U. S. was $3,180,000,000, a drop of 33% from 1930. The value of metallic products ($567,200,000) declined 42%. Notable decreases in value, 44-54%, were recorded for Cu, Fe, Ag, Pb and Zn. Value of Au production increased 5%. W ore (60% concentrates) doubled in output and almost doubled in value. Hg increased in output and decreased only slightly in value. Chromite and Ni (both small outputs) increased. All other metallic products decreased. Output of nonmetallic mineral products declined 31% and mineral fuels 32%. AHE (16)

The Cost of Dust in the Steel Foundry. Clarence B. Bartlett. *Paper* before the *Steel Founders' Society,* New York, May 1932, 16 pages.

A survey of the dust conditions in large industrial plants in general and steel foundries in particular is made in its bearing on the health of the workmen, labor turnover, efficiency, etc. and on the compensation and insurance payments. The stand taken by insurance companies on professional diseases, particularly "silicosis" in foundries, by different states are reviewed and concerted action is recommended in the prevention of dust. An outline for such action is suggested. Ha (16)

Lead in the Depression. Clinton H. Crane. *Mining & Metallurgy,* Vol. 13, Feb. 1932, pages 91-94.

U. S. production of Pb for 1931 was about 400,000 tons. This is the smallest production since 1911 and 1912, but in spite of this, stocks increased nearly 50,000 tons. Estimate of production outside of U. S. was 1,120,000 tons. Curtailment in domestic production has been due to price. Pb content of scrap battery receipts by secondary and primary smelters was 140,000 tons in 1931. Approximately 68% of the Pb used in batteries comes back into use. Therefore only 4,000 tons of new Pb for batteries was needed. Gives table comparing consumption of Pb in U. S. in recent years with 1913. VSP (16)

The German Iron and Steel Foundries in the Light of Government Statistics. (Die deutschen Eisen- und Stahlgiessereien im Lichte der amtlichen Statistik.) Adolph von Buelow. *Die Giesserei,* Vol. 19, June 10, 1932, pages 230-235.

Total production, quantity, value, average value per ton, charges, amount of raw material and refined material, cost of material and labor, scrap and distribution of consumption are statistically compiled for the years 1911-1913 and 1924-1931. Ha (16)

PLANTS & LABORATORIES (17)

Mines Branch Radium Plant. W. M. Goodwin. *Canadian Mining Journal,* Vol. 53, June 1932, pages 253-255.

A brief description of the Government Experimental plant for Ra extraction from Great Bear Lake ores. WHB (17)

Eaton Axle Company. R. P. Brown. *Heat Treating & Forging,* Vol. 18, Mar. 1932, pages 197-199.

Description of heat treating practice and equipment in the axle and gear plant in Cleveland. MS (17)

Otis Steel Company. Charles Longenecker. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 89-100.

Illustrated description of the equipment of the Company with special reference to the Riverside plant. Comprises 100 Semet-Solvay coke-ovens, 2 blast furnaces, eight 150-ton open-hearth furnaces, 13 soaking pits, 40″ blooming-mill, 2 continuous heating furnaces, 72″ and 20″ hot strip mills, 72″ cold strip mill, sheet mills and an 84″ plate mill. MS (17)

Pretoria (Africa) a New Center of the Steel Industry. [Pretoria (Afrika) ein neuer Mittelpunkt der Eisenindustrie.] Kurt Guthmann. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Aug. 14, 1932, pages 427-428.

Blast furnace, stoves and the electric gas purification plant, system Lurgi, of the Pretoria steel plant are described and compared with that of the new German blast furnace plant at Huckingen. The Pretoria plant is to start operation by July 1933. The new plant is expected to compete successfully with the European steel imported into South Africa. GN (17)

A Model Metal Coating Research Laboratory. E. F. Berry. *Metal Industry,* N. Y., Vol. 30, June 1932, pages 229-230.

A description is given of the new quarters of the Udylite Process Company. PRK (17)

Hansell-Elcock Company. J. B. Nealey. *Heat Treating & Forging,* Vol. 18, Apr. 1932, pages 263-264.

Description of a combination core-baking and mold-drying oven installed in the foundry of the Hansell-Elcock Co., Chicago. MS (17)

New Reversible Ingot and Bloom Mill Trains. (Neue Umkehr-Block- und -Brammen Strassen.) Fritz Münker. *Stahl und Eisen,* Vol. 52, June 23, 1932, pages 601-606.

The reversible ingot and bloom mills at the Fenderie and Gross-Moyenvre Works of Les Petits Fils de Fois de Wendel & Cie are illustrated and described. DTR (17)

Canada Backs Research with $3,000,000 Building. E. G. Wilson. *Power,* Vol. 75, June 7, 1932, pages 837-840.

The new laboratory building of the National Research Council of Canada is described. AHE (17)

Aluminum Melting in the Electric Furnace. Wirt S. Scott. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1055-1058.

Practically the same as an article published in *Foundry,* Vol. 59, Oct. 1, 1931, pages 67-68. It contains an additional log of power consumption and operating costs for coke and gas furnaces. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 76. MS (17)

The Laboratories of the Ore Dressing and Metallurgical Division, Mines Branch, Department of Mines, Ottawa. C. S. Parsons. *Canadian Mining & Metallurgical Bulletin* No. 241, May 1932, pages 249-251.

Discussion. See *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 47. AHE (17)

New Beam Mill Rolls Wide Flange Structural Shapes. *Steel,* Vol. 90, Mar. 21, 1932, pages 31-33, 40.

A description of the new wide flange beam mill at the South Chicago, Ind., works of the Illinois Steel Co., including control and driving equipment, soaking pits, roughing and intermediate mills, transfer equipment, etc. JN (17)

Continuous Plate and Strip Sheet Mill now in Operation. *Steel,* Vol. 90, Mar. 28, 1932, pages 31-33; *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 268-269.

A description of the new plate and strip mill recently constructed for the Inland Steel Co. at Indiana Harbor, Ind. JN + MS (17)

The Foundry Institute of the Technical Hochschule in Aachen. (Das Giesserei-Institut der Technischen Hochschule in Aachen.) *Stahl und Eisen,* Vol. 52, July 7, 1932, pages 664-665.

Diagrammatic sketch is given of the new metallurgical section of the Foundry Institute of the Technische Hochschule in Aachen, Germany. Location of the 25 experimental foundry furnaces, machines, etc., is designated in the 25 m. x 18 m. hall. DTR (17)

Open-Hearth Facilities Expanded. *Steel,* Vol. 90, Feb. 29, 1932, pages 23-25.

The Illinois Steel Co. has erected 7 new basic open-hearth furnaces at their Gary, Ind., works and 21 at their South Chicago, Ind., works. This brings the total number of basic units owned by the company in the Chicago district to 95 with an annual ingot production of 9,230,000 tons. The two sets of furnace installations and their accessory units are described. JN (17)

A Modern Ingot Mould Foundry. *Foundry Trade Journal,* Vol. 46, Apr. 21, 1932, pages 245-247.

An article dealing with the works of the Fullwood Foundry Company, Limited, Mossend, Scotland. OWE (17)

Continuous Manufacture of Welded Tube. *Iron & Coal Trades Review,* Vol. 124, June 3, 1932, page 918.

A detailed description of the manufacture of welded pipe from skelp to the finished and galvanized product in the plant of the Fretz-Moon Tube Co., Butler, Pa., is given. The skelp moves from 150 to 225 ft./min., according to the thickness which varies from 0.065″ to 0.154″ and the width from 1 9/32″ to 9 1/4″. The continuous feature is obtained by using coiled skelp in lengths from 300 to 1500 ft. and welding one coil to the next; the pipe is butt-welded. The galvanizing pot is top-fired. Ha (17)

Present State of Construction of the Russion Steel Plant Kusnetskstroy. (Stand der Arbeiten an dem russischen Hüttenwerk Kusnetskstroy.) *Die Metallbörse,* Vol. 20, Jan. 2, 1932, page 9.

Reviews the projected Siberian Steel Plant Kusnetskstroy with emphasis on its capacity and presents data on the present output of this plant. EF (17)

MACHINERY & SUPPLIES (18)

Grading by Sifting of Grainy Material; Study of Modern Grading Apparatus. (Note sur le Calibrage des Matieres Minerales Grenues; Etude de quelques Appareils Cribleurs Modernes.) F. J. Pirlot. *Revue Universelle des Mines,* Series 8, Vol. 7, Feb. 15, 1932, pages 136-190. 1

A very comprehensive review is given of the principles of grading of materials by separating the different grain sizes and freeing it from the dust. An analytical treatment of the practical determination of the average size of a grain is developed and apparatus described which has been developed according to these principles. 20 references. Ha (18)

The Design and Application of Cranes to Steel Mill Service. Part III. G. W. Yanney. *Rolling Mill Journal,* Vol. 5, May 1931, pages 359-362.

A discussion of the advantages obtained by the use of the internal expanding type of hydraulic brakes developed for steel mill crane service from the automobile field. The advantages claimed are complete assembly in the machine shop, ease of adjustment in the field, the use of closer clearances, ready accessibility, greater ease of operation, ready equalizing of brake pressures, compactness of design and added safety. JN (18) 2

Conveying in Foundries. (Das Transportwesen im Giessereibetriebe.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Apr. 3, 1932, pages 139-141.

It is shown how a good system of transportation increases the production, decreases the expenses for unproductive wages, and promotes an all-around efficiency in foundries. The great advantage of electric auxiliary equipment, as electric cars, electric hoists, etc. is emphasized. GN (18) 3

Savings Due to Electrodes of Natural Graphite. Correspondence from F. Giolitti. *Metal Progress,* Vol. 21, Mar. 1932, pages 68-69.

Lists properties of natural graphite electrodes now being manufactured in Italy. These electrodes are 15-20% cheaper than graphitized electrodes. WLC (18)

New Drilling Machine for the Bearings of Locomotive Axles. (Neues Bohrwerk für Lokomotivachslager.) W. Pilz. *Glasers Annalen,* Vol. 110, Apr. 15, 1932, pages 73-75. 4

Detailed description including operation of a new drilling machine for drilling the bearings of locomotive axles. The machine is built by Vulkanhammer-Maschinenfabrik, Berlin—Neukoeln, Germany.

Wire Straightening and Cutting Machine (Draht- Richt- und Abschneidemaschinen). *Stahl und Eisen,* Vol. 52, Jan. 14, 1932, page 43.

A new machine for straightening and cutting wire is described briefly. The machine is built by the Deutsche Maschinenfabrik, Duisburg. GN (18)

Recent Developments in Molding Machines in Germany. H. Illies. *Iron & Steel Industry & British Foundryman,* Vol. 5, Mar. 1932, pages 223-227. 5

Description of various manual and mechanical molding machines. CHL (18)

The S I P Accuracy-Coordinate Drilling Machine. (Die S I P Genauigkeits-Koordinatenbohrmaschine.) H. Kitzerow. *Zeitschrift für wirtschaftliche Fertigung,* Apr. 1932, pages 46-48.

A new unique machine tool is described which combines a measuring apparatus of highest accuracy with an efficient drilling machine. GN (18)

Leipzig Spring Fair 1932. (Leipziger Frühjahrsmesse 1932.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Apr. 3, 1932, pages 133-134. 6

This is a brief resumé on new foundry equipment exhibited at the 1932 Leipzig Spring Fair. There are mentioned: Sand dressing machines, grinding machines, annealing pots, melting furnaces, die and press casting machines, material testing machines, temperature measuring apparatus and other foundry equipment. GN (18)

Charging Cranes and Machines. (Beschickkrane und Beschickmaschinen für waagerechte Ofenbeschickung.) *Demag Nachrichten,* Vol. 6, Mar. 1932, pages 9-13; *Demag News,* Vol. 6, Mar. 1932, pages C9-C13. 7

Illustrated description of new constructions of charging cranes and machines for open hearth and rolling mill furnaces. Ha + GN (18)

A Novel Core-Shop Tool. *Foundry Trade Journal,* Vol. 46, Mar. 3, 1932, pages 141, 144.

A description of the foundry of Messrs. Newman, Hender and Company, Woodchester, England. Particular attention is paid in this article to an air-operated core-box vise, which has recently been designed and placed on the market. OWE (18) 8

Possibilities for Development of Steam Turbines. (Entwicklungsmöglichkeiten im Dampfturbinenbau.) W. Kaiser. *Maschinenbaukonstrukteur-Betriebstechnik,* Vol. 64, Aug. 10, 1931, pages 170-172.

The article is a general discussion of steam turbines and their future with regard to feed pipes, transition to higher steam temperatures, the influence of the size of machines on cost of installation, increasing the factors of safety in operation by careful construction and knowledge of properties of the materials, limits for efficiency, improvements, superheating, and 2-phase operation. MAB (18) 9

Improves Ladle Stoppers by Drying in Vertical Oven. L. F. Reinartz. *Steel,* Vol. 90, Feb. 22, 1932, pages 23-24.

A description of the new vertical drying oven and transferring equipment installed in the open-hearth department of the Middletown, O., plant of the American Rolling Mill Co. for drying and handling newly built ladle stoppers while keeping them in a permanently vertical position. JN (18)

Air Brake on Machine Tools. L. J. Berkeley. *Machinery,* Vol. 38, Mar. 1932, pages 481-485.

Describes and illustrates air operated brakes which permit instantaneous stopping of machine tools. By using reversing type motors the rotation of the tool on drilling or milling machines and the rotation of the work on lathes, can be immediately reversed. Taps may be removed by the same methods. Another feature described is a means of maintaining constant tension on the belts. RHP (18) 10

BIBLIOGRAPHIES (19)

Chromium Plating Literature (V). L. H. Decke. *Brass World*, Vol. 28, June 1932, pages 118-119.

This installment continues the review of the literature on anodes for Cr plating. WHB (19)

Progress in Foundry Practice for First Half 1931. (Fortschritte im Giessereiwesen im ersten Halbjahr 1931.) Hans Jungbluth & Paul A. Heller. *Stahl und Eisen*, Vol. 52, Mar. 24, 1932, pages 289-294; Mar. 31, 1932, pages 313-315.

Bibliography of iron foundry work for 1st half 1931, containing 106 references. Subdivided into following headings: (1) Composition & properties of cast iron; (2) melting; (3) molding & dressing; (4) general practice. The gist of each article is summarized. DTR (19)

Beryllium, A Bibliography. Mary E. Hoyt & Karl Von Den Steinen. *Colorado School of Mines Quarterly*, Vol. 26, Oct. 1931, 35 pages.

A bibliography of several hundred references on Be which is classified according to the following headings: (1) History and Development, (2) Ores, Sources, Distribution in Nature, (3) Chemical and Physical Properties, (4) Determination, (5) Extraction and Production, (6) Alloys, (7) Marketing and Consumption, (8) Books, (9) Patents, Foreign and Domestic. WAT (19)

Bibliography of Aeronautics, 1930. National Advisory Committee for Aeronautics. Government Printing Office, Washington, D. C., 1932. Paper, 7 x 10¼ in., 261 pages. Price 50 cents.

The Bibliography of Aeronautics for 1930 covers the aeronautical literature published from January 1 to December 31, 1930. The first Bibliography of Aeronautics was published by the Smithsonian Institution as Volume 55 of the Smithsonian Miscellaneous Collections and covered the material published prior to June 30, 1909. Supplementary volumes of the Bibliography of Aeronautics for the subsequent years have been published by the National Advisory Committee for Aeronautics.

As in previous volumes, citations of the publications of all nations are included in the languages in which these publications originally appeared. The arrangement is in dictionary form with author and subject entry, and one alphabetical arrangement. Detail in the matter of subject reference has been omitted on account of the cost of presentation but an attempt has been made to give sufficient cross reference for research in special lines. Progress in Coke During 1931. (Fortschritte im Kokereiwesen im Jahre 1931.) W. Melzer. *Stahl und Eisen*, Vol. 52, Apr. 14, 1932, pages 367-370.

Bibliography of progress in coke and coke industry for 1931, containing 51 references, with brief summary of each article. DTR (19)

Review of Iron and Steel Literature for 1931. E. H. McClelland. *Blast Furnace & Steel Plant*, Vol. 20, Jan. 1932, pages 75-79; Feb. 1932, pages 184-185.

15th annual classified list of the more important books, serials and trade publications during the year with a few of earlier date, not previously announced. The list has been reprinted by the Carnegie Library of Pittsburgh and may be obtained free at the Library or for 5 cents, post-paid. MS (19)

Progress in the Plating Technique. (Fortschritte in der Galvanotechnik.) H. Kurrein. *Oberflächentechnik*, Vol. 9, May 24, 1932, pages 97-99.

In the field of modern electroplating technique 3 main directions of endeavor can be distinguished. (1) To determine by research work the conditions for obtaining high class work. (2) To facilitate economy in operation by improving apparatus, baths and methods. (3) To create new fields of application. These fields are reviewed singly with regard to Cd, Zn, Cu, Ni, Cr, Sn, Pb, rare metals and non-metallic protective coatings for Al. The patent literature and 93 other bibliographic references are cited. Ha (19)

The Determination of Oxygen in Iron Alloys by the Hydrogen-Reduction Method. (Ein Beitrag zur Frage der Sauerstoffbestimmung in Eisenlegierungen nach dem Wasserstoff-Reductionsverfahren.) Herbert Petersen. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen*, Vol. 11, 1932, 14 pages.

The difficulties of the exact determination of O in Fe alloys and the various methods are critically discussed. In order to take into account the CO which is developed by applying the H-reduction method, the CH_4 synthesis according to Sabatier and Senderens was employed which consists in a reduction of the CO to CH_4 and H_2O by means of a finely distributed 10% thorium oxide containing Ni catalyzer at 250° C. The theory of this method is derived, its accuracy determined and the apparatus used in it described. The advantages of this method are compared with the new hot-extraction method. 178 references. MISCELLANEOUS (20)

The Temperature Coefficient of the Thermal Decomposition of Ammonia on Platinum. J. K. Dixon. *Journal American Chemical Society*, Vol. 53, June 1931, pages 2071-2074.

1 The decomposition of ammonia on Pt gauze has been studied between temperatures 772 and 858° C. The heat of activation of the reaction is in agreement with the values obtained for a number of other metals. MEH (20)

Investigations of Equilibrium in Reducing, Oxidizing and Carburizing of Iron. X. (Gleichgewichtsuntersuchungen über die Reduktions-, Oxydations- und Kohlungsvorgänge beim Eisen. X.) R. Schenck, Th. Dingmann, P. H. Kirscht & A. Kortengraeber. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 206, May 18, 1932, pages 73-96.

2 The conditions under which reduction, oxidation and carburization of thin Fe films can take place are described and compared with the results of other investigators. Ha (20)

Investigations of Equilibrium in Reducing, Oxidizing and Carburizing of Iron. XI. (Gleichgewichtsuntersuchungen über die Reduktions-, Oxydations- und Kohlungsvorgänge beim Eisen. XI.) R. Schenck, H. Franz & A. Laymann. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 206, June 1, 1932, pages 129-151.

3 The influence of the oxides of Si, Ti and P on the reduction equilibrium was investigated in order to elucidate the conditions when the oxides of Fe can form, with the added oxides, either solid solutions or chemical compounds. The results are reproduced in tables and diagrams to which the reader is referred. In an appendix, the action of Cr_2O_3 is described; the reducibility of Cr_2O_3 and also of its mixtures with small amounts of Fe is much lower than that of other oxides. Ha (20)

The Compression Stresses of Clamped Rectangular Plates. (Die Knickspannungen von eingespannten rechteckigen Platten.) Ferd. Schleicher. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns*, Vol. 1, Dec. 1931, pages 186-193.

4 The theoretical analysis shows that the clamping on the edges is of essential influence only for approximately square plates. Diagrams are given. Ha (20)

The Mechanics of Plastic Bodies. (Mechanik deformierbarer Körper). K. Weissenberg. *Forschung, Zeitschrift Technische Mechanik und Thermodynamik*, Vol. 3, Jan./Feb. 1932, pages 51-52.

Brief discussion of the theories which play a role in the plasticity of matter. GN (20)

On Stability Problems of Thin Cylindrical Shells. (Über Stabilitätsprobleme dünner, kreiszylindrischer Schalen.) K. von Sanden & F. Tölke. *Ingenieurarchiv*, Vol. 3, Mar. 1932, pages 24-66.

5 The paper first gives a survey on previous investigations on the mechanical forces in hollow cylindrical bodies. 13 references. GN (20)

Magneto-Resistance and Magneto-Caloric Effects in Iron and Heusler Alloys. H. H. Potter. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Ser. 7, Vol. 13, Feb. 1932, pages 233-248.

Extensive research of a technical and mathematical character. RHP (20)

Determination of Stresses in Rotating Disks of Conical Profile. F. C. Rushing. *Transactions American Society of Mechanical Engineers*, Vol. 53, 1932, Applied Mechanics, pages 91-98.

6 The accuracy of stress distribution curves obtained by the application of the theory of Donath of "sum and difference curves" as applied to rotating disks of conical profile is investigated; it is found that the calculated curves always give a somewhat higher value than that actually occurring. 4 equal subdivisions of the disk along its radius give satisfactory results. To assume only one equivalent disk of uniform thickness is admissible and satisfactory only if the speed is not too high and the taper not too large. A 2-division method is developed which gives accurate results in all cases. Ha (20)

Stress Distribution in a Flank Weld Seam. (Spannungsverteilung in einer Flankenschweissnaht.) Petermann. *Stahlbau*, Supplement to *Bautechnik*, Vol. 5, June 10, 1932, pages 92-93.

8 The stress distribution in a continuous flank seam was found by making a limit transition from the stress distribution of the individual rivets in a rivet row. The result of the calculation is shown in a numerical example. The size of the maximum stress decreases but to a relatively small extent with increasing length of the seam. Under the conditions considered the curve of the shear stresses in the flank seam is symmetrically arranged to the middle of the seam. 2 references. GN (20)

Stresses in Curved Bars. H. C. Perkins. *Transactions American Society of Mechanical Engineers*, Vol. 53, 1931, Applied Mechanics, pages 201-205.

Simple formulas are developed for computing the stresses in curved bars with practically sufficient accuracy with the slide rule. A few examples are given. Ha (20)

Strength of Thin Cylindrical Shells under External Pressure. Harold E. Saunders & D. F. Windenburg. *Transactions American Society of Mechanical Engineers*, Vol. 53, 1931, Applied Mechanics, pages 207-218.

9 The problem of the design of cylindrical vessels or tubes under external pressure has become of great importance in modern industrial processes, for instance, materials under a vacuum or double-walled chambers whose jackets are filled with steam under high pressure. The paper offers a theoretical treatment of questions involved in the design and tries to determine empirical constants and coefficients. Experiments were made to verify some values but it is emphatically pointed out that in the use of numerical constants the question of geometrical and physical similarity of the bodies to be designed with those whose constants are used, is of utmost importance. A few suggestions are made on the selection of the factors of safety, and diagrams showing the relation of stresses to the physical dimensions given. Ha (20)

Improved Lighting As an Aid to Industrial Efficiency. H. LINGARD. *Foundry Trade Journal,* Vol. 46, Apr. 21, 1932, pages 250-252.

An extended abstract in which attention is drawn to the fact that only 30% of the factories investigated by the Electric Lamp Manufacturers' Association, of Great Britain, were employing modern lighting equipment, and that of that 30% only half had lighting which could be classified as good. Transmission of Torque by Means of Press and Shrink Fits. J. W. BAUGHER. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 85-92.

The most important formulas for calculating the stresses occurring in press and shrink fits are presented and charts developed to readily obtain numerical results when steel shafts and cast iron or steel outer members are used. Values of coefficients of friction are derived for use in computing the probable tonnage required for a fit and the torque capacity if no key is used; formulas for tonnage and torque capacity are given. 16 references. Ha (20)

Spiral Springs. J. A. VAN DEN BROEK. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Applied Mechanics, pages 247-263.

A theory is developed relative to the stress, strain and energy functions of spiral springs which takes into account the large deformations occurring in the action of large springs. The theory leads to the suggestion that springs should be loaded in such manner that all locally overstressed points as well as all friction between leaves are eliminated so that no grease or graphite need be employed and the efficiency of the springs thereby considerably increased. Ha (20)

The Calculation of Uniformly Loaded Rectangular Plates which are Supported by Elastic Beams at 2 Opposite Edges. (Die Berechnung rechteckiger, gleichförmig belasteter Platten, die an zwei gegenüberliegenden Rändern durch elastische Träger unterstützt sind.) E. MÜLLER. *Ingenieurarchiv,* Vol. 2, Jan. 1932, pages 606-621.

The calculations were carried on according to a method described by Nadai. Die elastischen Platten, page 120; Julius Springer, Berlin, 1925. GN (20)

Stresses in Dished Heads of Pressure Vessels. CYRIL O. RHYS. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Petroleum Mechanical Engineering, pages 49-65.

A theory of the bending stresses of heads for double-radius head profiles and a method for obtaining the profile of least stress for given diameter and depth of head are developed and the theoretical and experimental results compared. The procedure of calculation is outlined. The results of tests are given which were made over several years with large drums of high internal pressure; the bending stresses are more critical than the meridional-loop stresses. Ha (20)

Strain and Change of Shape of Girder Constructions at Vibrations (Beanspruchung und Formänderung von Stabwerken bei erzwungenen Schwingungen.) S. GRADSTEIN & W. PRAGER. *Ingenieurarchiv,* Vol. 2, Jan. 1932, pages 622-650.

In this paper, for the first time, there have been calculated steel constructions from the dynamic point of view. Methods are developed for calculating the strain and deformation in a girder construction when a load is suddenly applied or lifted and for loads which, when of unvariable size, move along the construction or periodically change in size with the point of application being fixed. The paper particularly considers the case of a girder construction which is subjected to periodically alternating loads with fixed point of application. The method of calculation takes into consideration merely the transversal vibrations. 4 references. GN (20)

British and American Rolled Steel Sections. B. L. HURST. *Engineer,* Vol. 153, Feb. 5, 1932, pages 148-149.

Comments on the revised list of British Standard Channels recently published by the British Standards Institution. A table and graph are given comparing the efficiencies of British and American structural beams of various depths. LFM (20)

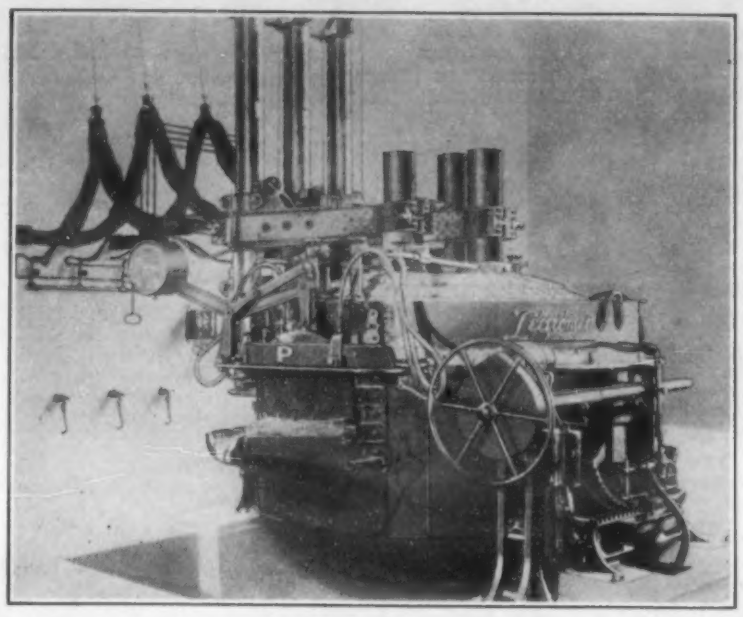
The Activations of Metals by Foreign Additions. II. (Ueber die Aktivierung der Metalle durch fremde Zusätze. II.) R. SCHENCK, FR. KURZEN & H. WESSELCOCK. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 206, June 18, 1932, pages 273-288.

The activation of metals can be influenced first, by the degree of distribution of the metal and, second, by the addition of oxides. Experiments with Fe and W showed that the formation of carbides of these 2 metals by CH_4 is made more difficult if one C atom is bound to several metal atoms in the carbides, as in Fe_3C or W_5C_2. Additions of indifferent oxides do not prevent formation of carbide if the latter consists of the same number of metal and C atoms, as in WC. Ha (20)

Distribution of Stresses in Simple Cranks. (Ueber die Spannungsverteilung in einfachen Kröpfungen.) F. ROETSCHER & J. CRUMBIEGEL. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, May 21, 1932, pages 508-509.

A theoretical analysis of the stress distribution. Near the lubrication hole of the crank the tensile stress increased 42%. Ha (20)

On the Deflection of Thin Rectangular Plates by Circular Loads. (Über die Biegung dünner rechteckiger Platten durch Kreislasten.) S. WOINOWSKY-KRIEGER. *Ingenieurarchiv,* Vol. 3, June 1932, pages 236-250.



Investigations of the state of stress in plates loaded by circular loads. The previous methods of calculation by Nadai and Lewe are briefly reviewed. The author's solution of the problem is based on Kirchhoff's theory on plates. 15 references. GN (20)

Number of Order and Heat of Formation. (Ordnungszahl und Bildungswärme.) W. A. ROTH & G. BECKER. *Zeitschrift für physikalische Chemie,* Abt. A. Vol. 159, Mar. 1932, pages 1-26.

Diagrams are presented in which formation heat is plotted against order of number referring to oxides, chlorides, and chloride solutions respectively. Group 1-6 of the periodic system is included. The data refer partly to new determinations and are partly calculated from previous results which are discussed critically. A straight line relationship, which was formerly often assumed, was found in only exceptional cases. Sometimes the curves predict or prove that data picked from literature must be erroneous. Employing elements in highly pure state, the formation heat of the following oxides were redetermined in the calorimetric bomb at 20° C. and constant pressure: $Ga_2O_3 = 255.8$ kcal, $SiO_2 = 207.8$ kcal, $TiO_2 = 218.7 \pm 0.3$ kcal, $ZrO_2 = 258.1 \pm 0.6$ kcal, $HfO_2 = 271.5$ kcal, $ThO_2 = 292.6 \pm 1.4$ kcal. Furthermore the formation heats of the following compounds were recomputed: $SiCl_4 = 154.0$ kcal, $TiCl_4 = 185.0$ kcal, ZrC = 45 kcal, ThC = — 194.79 kcal, TiC = 114 kcal. The specific gravity of Th was found to be 11.71. EF (20)

The Engineer in a Changing Society. WILLIAM E. WICKENDEN. *Electrical Engineering,* Vol. 51, July 1932, pages 465-471.

An address. Every revolutionary movement has tended to augment the engineer's sphere of social responsibility. The educators must develop men who are able to deal in a more statesmanlike manner with the major economic and social problems of a technological era. WHB (20)

Modern Lectromelt Tool and Stainless Steel Furnace of the Door Charge Type.

LECTROMELT Furnaces are also furnished in the Patent Swing Roof-Quick Top Charge Type for Drop Bottom Bucket Loading.

Users include many of the Leading Heat and Corrosion Resistant Alloy Manufacturers . . . Their operations are marked by

LOW OPERATING COSTS
HIGH QUALITY OF PRODUCTS
and
EXACT CONTROL OF CARBON AND ALL ALLOYS

A large number of Lectromelt Furnaces are also used for Plain and Alloy Irons such as cam shafts, brake drums, cylinder blocks, pistons and piston rings, abrasive irons, etc. . . . For limited outputs Lectrosimplex single phase furnaces are also manufactured.

FOUNDRY PRACTICE & APPLIANCES (22)

1 **Cause and Prevention of the Formation of Scum in Aluminum-Bronze and Special Brass. (Schaumbildung bei Aluminium-Bronze und Sondermessing, Ursache und Bekämpfung.)** *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 21, 1932, pages 331-333.

Since the pronounced tendency of Al alloys to form scums is due to occurrences of oxidation, special precautions are necessary to avoid oxidation. These precautions are discussed. Of great importance is the casting procedure. Rising pouring is preferable. The proper arrangement of gates and risers as well as special devices to keep slags from the mold are discussed. The paper also refers to American practice in casting Al-bronzes and deals with the use of skim cores. The effect of the casting temperature on the formation of scums is mentioned. GN (...

2 **Hints for Drilling Molding Flasks and Tables of Molding Machines. (Winke zum Bohren der Formkästen und Formmaschinentische.)** *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 29, 1932, pages 231-232; June 12, 1932, pages 250-251; June 26, 1932, page 272.

The drilling of guide holes in flasks and tables of molding machines as well as the drilling of threaded holes for screwing on patterns are dealt with. GN (22)

3 **Mould Density Determination.** WM. Y. BUCHANAN. *Foundry Trade Journal,* Vol. 46, May 19, 1932, page 302.

The author discusses an example of the practical application of the penetration method of measuring the degree of ramming in molds, which has been described elsewhere. The principal of the penetration method is that a 1/8" diameter steel wire is driven into the sand by the blow of a falling weight under standard conditions. The uniformity of the degree of ramming in individual molds may be thus determined, and the case under discussion in this article is evidence in support of the author's statement. The author points out that the penetration method can be used as a check on routine production where liberties may be taken with the amount of sand used, the pressures employed, etc. The advantages of such control are: (1) the ability to check any mold at a moment's notice; (2) having determined the most suitable degree of ramming for a particular job and class of sand, this can be adjusted with certainty and checked as often as necessary; and (3) by the methods described in the article the degree of ramming of any part of a mold relative to the rest of the job can be adjusted. OWE (22)

5 **Molding Devices which the Pattern Maker Makes. (Formeinrichtungen, die der Modellbauer ausführt.)** *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 12, 1932, pages 248-250.

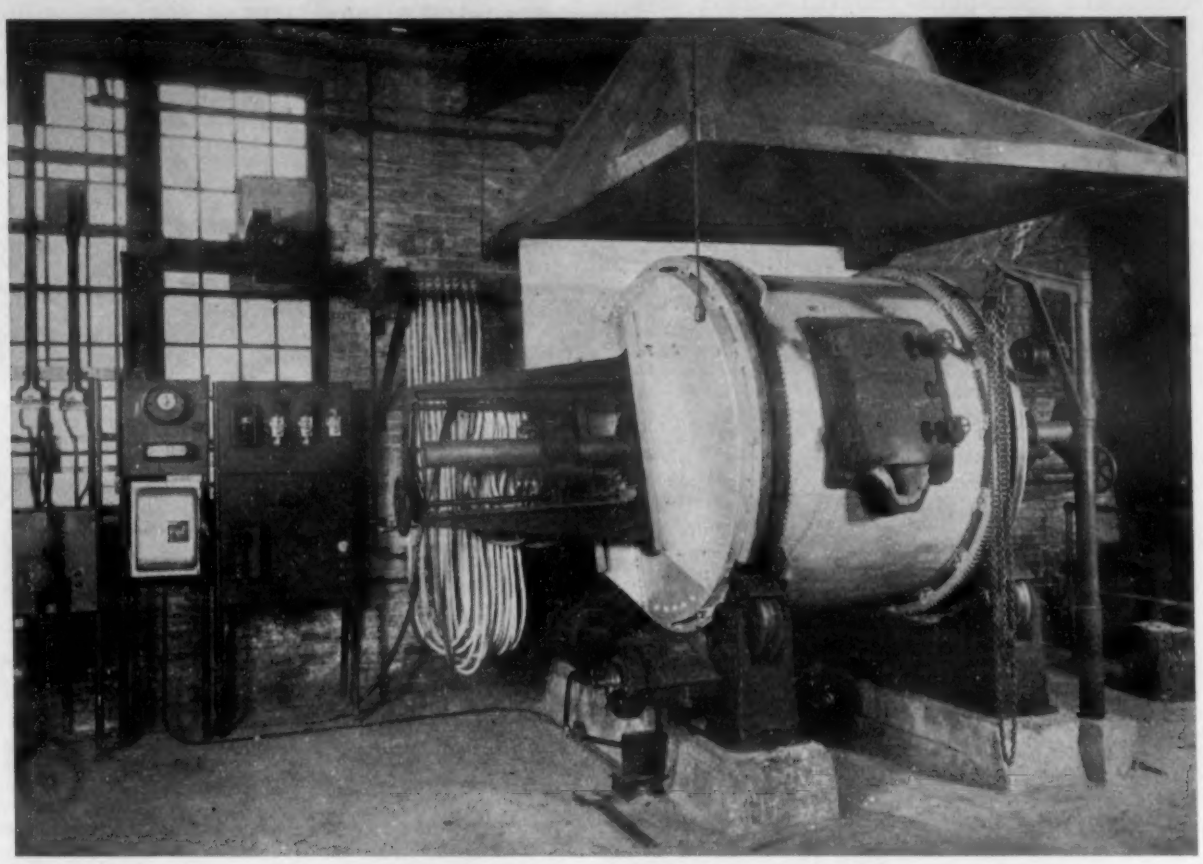
Some examples are discussed which are to show how sand molding of certain shapes is facilitated by simple devices made in the pattern shop. GN (22)

Some Aspects of Oil Engine Foundry Practice. HERBERT E. BEARDSHAW. *Foundry Trade Journal,* Vol. 46, June 23, 1932, pages 385-389.

The author emphasizes the need for consultation between the designers of castings and the foundry, particularly when the more intricate and costly types of casting are being considered. Attention is directed to the materials used in
6 foundry practice for types of casting manufactured in oil engine foundry practice—namely, fly-wheels, cylinder heads and blocks, and larger castings. Casting stresses receive some attention. Author's view on the testing and examination of foundry materials is given. OWE (22)

Manufacture of Acid-Proof Bronzes. (Herstellung von Säurebronzen.) R. BERGER. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 1, 1932, pages 184-185.

The paper outlines the procedure to be followed in melting a bronze of high stability against HCl, H_2SO_3, Na_2SO_4, and alkaline bearing water. This bronze contains about
7 83.9% Cu, 8% Sn, 6% Pb, 2% Ni, .1% P. In order to attain a high corrosion resistivity it is absolutely necessary to insure the absence of Fe and Zn. Therefore, the raw materials must be carefully selected. If this bronze is melted under the precautions given the castings are dense and possess a high toughness. GN (22)



Charges with a High Content of Scrap Iron. (Eisengattierungen bei höherem Gussbruchzusatz.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 19, 1932, pages 214-215.

The paper first outlines the disadvantages of a high content of scrap Fe in the charge. They are: enrichment of the
8 S content, increased hardness and, therefore, poor machinability, and finally increased tendency to porous castings, particularly when the scrap Fe is very rusty. The remedies are discussed: desulphurization is suitably attained in a forehearth or, if a forehearth is not available, S should be decreased by high furnace temperatures and the addition of special admixtures, composed of 2 parts of limestone and 1 part of fluorspar. 2 kg. of this mixture are used per 100 kg. of the charge. The addition of special irons containing 0.5-1.0% Si and 3-4% Mn is also advisable. The brittleness of cast
9 Fe made from charges with a high amount of scrap Fe can be counteracted by varying the Si content:

Wall thickness of the casting in mm.	Si in the casting for 50-55% scrap	60-65% scrap
Below 10	2.6-2.8%	2.8-3.0%
10-20	2.4-2.6%	2.6-2.8%
20-30	2.2-2.4%	2.4-2.6%
30-40	2.0-2.2%	2.2-2.4%
Above 40	1.8-2.0%	2.0%

10 The Mn content should not be below 0.8%. In order to counteract the impairing effect of scrap Fe on the tensile properties of the Fe, steel scrap or the above special Fe should be added. To avoid the tendency to porosity the furnace should be run as hot as possible, and the Fe also cast as hot as possible. In following the above rules the price of cast Fe can be decreased by using a higher amount of scrap without impairing the quality of the Fe made. GN (22)

PRECISE CONTROL

THE DETROIT ROCKING ELECTRIC MELTING FURNACE FOR GRAY IRON, MALLEABLE, ALLOY STEEL . . . AND ALL NON-FERROUS METALS

offers unequalled facilities for the economical production of various types of castings with precision in chemical and physical characteristics. The accuracy of temperature control and complete homogeneity which are insured by the rocking action of the DETROIT Electric Furnace, together with its simplicity of operation, are determining factors in the highly satisfactory results being obtained by over sixty users in the ferrous field and over five hundred users in non-ferrous melting.

FURNACES & FUELS (23)

A New Electric Melting Furnace of the Induction Type. (Ein neuer Elektro-Schmelzofen nach dem Induktionsprinzip.) U. SCHWEDLER. *Elektrowärme*, Vol. 2, Mar. 1, 1932, pages 59-62.

A new construction of an induction type furnace is described which can be used for low frequencies as they exist in distributing systems and for 3-phase current so that both the transformation into high-frequency and the lead load distribution with a single phase furnace are eliminated. The heat is produced by the eddy currents induced in the material to be melted. The winding is arranged in the same way as in an induction motor so that a rotating field exists into which the material is brought. The theory of the furnace is derived and was checked by a small experimental furnace. In order to keep the heat of the melt away from the winding water-cooled Cu pipes surround the bath. Ha (23)

A Four Ton High Frequency Induction Furnace. (Un four à induction à haute fréquence de 4 tonnes.) DUDLEY WILCOX. *Journal du Four Electrique*, Vol. 41, June 1932, pages 210-212.

A description is given of a new 4 ton induction furnace installed in 1931 at South Chicago Works of Illinois Steel Company. The housing of the furnace is made of steel lined with Cu. The temperature rise in it is but a few degrees. Magnesia-alumina mixture known as Almag is used successfully for lining. The furnace is fed with 12,000 amperes at 1,000 cycles produced by a motor generator set of 1,250 kwh. having 1,500 r.p.m. and located about 200 m. from the furnace. It is used largely for remelting stainless steel scrap. JDG (23)

The Coreless Induction Furnace in Modern Steel Plant Operation. (Der kernlose Induktionsofen im neuzeitlichen Stahlwerksbetrieb.) NINO BROGLIO. *Elektrowärme*, Vol. 2, July 1932, pages 150-156.

The characteristic properties of the coreless induction furnace are discussed. The melting crucible has a very favorable ratio of depth of bath to surface of bath for the required reaction, about 1:1.3 for a furnace with 2,000 kg. charge (5,000 kg. liquid charge). The crucible is made of any reliable heat resisting material and arranged within the Cu coil. The furnace is usually fed by a 3-phase - single phase MG-set with current of 1,200 to 1,300 volts at 2,000 cycles. Its particular advantage is its great flexibility so that it can be used for many metallurgical processes, and the high quality of the material produced. Furthermore, it works very rapidly and higher temperatures can be obtained with it than with other methods, up to 1800° C. without difficulty. As the heat is generated in the material itself and not supplied from outside the process is economical. The electrodynamic stirring of the bath (due to eddy currents) assures a great homogeneity of the melt and great uniformity of different melts. A melting schedule of a furnace for high-speed steel and a few other schedules are given in detail and compared with the open-hearth and Thomas processes. Ha (23)

Some Features of Coreless Induction Furnaces. A. D. MEYER. *Heat Treating & Forging*, Vol. 18, Apr. 1932, pages 257-259, 262.

A coreless induction furnace permits control equalled heretofore only by laboratory apparatus. Contamination of the metal is reduced to a minimum. High-alloy scrap can be remelted with practically no loss of alloys and no pick-up of contaminating materials and at practically any speed of melting desired. Gentle stirring of the bath promotes deoxidation and eliminates inclusions and segregation. D. J. Campbell has shown in *Journal Iron & Steel Institute*, Vol. 122, pages 85-94 that refining of steel in the induction furnace holds real possibilities. Several of his curves are reprinted. Duplex processes utilizing the induction furnace for final refining, deoxidation, and alloying are very promising. Linings are made of acid, basic or neutral refractories, the basic lining being favored in the United States. Acid linings are usually installed by the fused-in method, average life being about 50 heats. Both pre-fired crucibles and the fused-in method are used in basic furnace practice. Crucibles are not practical for furnaces of capacity greater than 1 ton. High-grade MgO and a suitable bond are used for crucibles. $ZrSiO_4$ is preferable for backing them. Average life of crucibles is about 90 heats for general steel melting, and is considerably longer when melting stainless steels. The induction furnace is admirably adapted to melting corrosion and heat resisting steels. Production of stainless steels with 0.04% C is easy. A total of 32,500 kw. of Ajax-Northrup furnaces has been installed up to 1932. The largest installation is a 4-ton furnace. MS (23)

Electric Furnaces in Mine Shop and Foundry. A. H. HUBBELL. *Engineering & Mining Journal*, Vol. 133, Aug. 1932, pages 442-445.

The electric furnace is applied in the mining industry in 4 ways: (1) for melting scrap in foundries, (2) for heating drill steel preliminary to forging it, (3) for heat-treating or tempering drill steel bits after each forging, and for heat treating or normalizing drill steel after resharpening. WHB (23)

Comparison of Bids for Resistance Furnaces. (Vergleich von Angeboten für Widerstandsöfen.) V. PASCHKIS. *Elektrowärme*, Vol. 2, Mar. 1, 1932, pages 54-59.

In order to be able to make a proper comparison of bids for electric furnaces a schedule is laid out in which the principal data are brought into such relation that a basis for comparison is found. In this schedule, the required energy per unit surface and per unit volume, the radiating surface, heating-up time, stored heat, regulation of temperature, etc. are taken into account. Ha (23)

Current Leads to the Electrodes of Electric Furnaces. (Les amenées de courant aux electrodes du four electrique.) *Journal du Four Electrique*, Vol. 41, June 1932, pages 213-214.

Excellent protection of the bus bars can be obtained by inserting them into flexible steel pipes through which water is circulating, cooling the electrode holders at the same time. Practical application of this device as made by La Societe des Electrodes de la Savoie was entirely successful. JDG (23)

Calculation of Inductance and Current Distribution in Low Voltage Connections to Electric Furnaces. C. C. LEVY. *Electrical Engineering*, Vol. 51, June 1932, page 406.

Formulas and methods are presented for the determination of the inductance of the relatively short connections between a transformer and an electric furnace in which the currents are very large and where the geometrical dimensions and arrangement of the conductors has to be taken into account. Practical applications of the formulas are shown by several examples. Ha (23)

Practical Study of the Operation of Electric Arc Furnaces for Alternating Current. (Etude pratique du fonctionnement des fours a arc a courant alternatif.) P. GONNARD. *L'Industrie Electrique*, Vol. 41, May 25, 1932, pages 221-227.

The theory of alternating current arc furnaces is developed and applied to practical questions such as self-regulation and the power factor for 3-phase and single phase furnaces. On account of the large currents in the conductors from transformer to furnace, attention must be paid to the manner of arranging these leads to the movable electrode and to the stationary part in order to avoid undue increase of the power factor. Ha (23)

The Theoretical Principles of the Induction Heating without Iron-Secondary Circuit. (Die theoretischen Grundlagen der Induktionsheizung ohne Eisenschluss.) W. FISCHER. *Elektrowärme*, Vol. 2, Feb. 1, 1932, pages 41-43; Mar. 1, 1932, pages 67-69.

The conversion of electrical energy into heat by induction at high frequencies without the use of an Fe circuit is derived theoretically with particular regard for the heating of small pieces. The screen effect determines the depth of penetration; a table is computed giving for Cu, Fe, Pb and graphite the most favorable diameter of a piece for frequencies up to 100,000 cycles and the conductivity of the respective material. A few furnace connections are given to show the possibilities of counteracting the reactance by capacitance. Ha (23)

Electric Furnaces. (Elektrische Öfen.) W. ROHN. *Die Chemische Fabrik*, Vol. 5, Apr. 13, 1932, pages 113-116.

Advantages of electric furnaces over other methods of heating are: (1) heat is produced where it is needed and does not have to be conducted through other materials; (2) efficiency is as high as 90%; for very high temperatures, 50 to 60%; (3) the temperature produced can be made equal to that needed and does not have to be higher as in a combustion zone; (4) the control is accurate and simple. For temperatures up to 300° C. the resistance of conducting metals is used to produce the heat. For temperatures between 300° and 1200° C. the resistance of other metals which are poorer conductors is utilized. Up to 700° C. stainless steel is satisfactory, from 650° to 1050° Cr Ni alloys and from 1050° to 1200° Cr Fe Al alloys; for units subject to corrosive atmosphere Cr Ni Mo alloys. It is important to choose the correct wire diameter and not to overload the wire. For 300°, 1 mm. wire is suitable; for 600°, 2 mm.; for 800°, 4 mm.; for 1000°-1050°, 6-8 mm. The maximum load/cm.^{2} of surface area of wire is 3-4 watts for 500°, 1 watt for 900°, 0.6 watt for 1000°, 0.3 watt for 1100°. For 1250° to 1400° C. ceramic units such as Globar are used. For processes which are carried out in an atmosphere of H_2 units of Mo or W are used, which can stand temperatures up to 2100° and 2800° respectively. The ends of the units are connected with the source of the current by water cooled Cu rings. If an H_2 atmosphere cannot be used in the heating chamber, a tube is wound with Mo wire and surrounded with H_2 or methyl alcohol vapor. Graphite heating elements can be heated up to 3000° C., but it is difficult to keep the connections cool. Still higher temperatures can be obtained with the electric arc, but they cannot be regulated. For melting metals at high temperatures the induction furnace can be used. CEM (23)

Industrial Electric Furnaces for Heat-treatment, etc. (Elektrische Industrieöfen für Weiterverarbeitung.) V. PASCHKIS. Julius Springer, Berlin, 1932. Cloth, 6¼ x 9¼ inches, 305 pages. Price 31.50 RM.

While the author acknowledges that some features of electric resistance furnaces cannot yet be calculated on an engineering basis, yet their design has advanced in so many points beyond the cut and try basis that is is possible to present much well-established engineering data in tables, curves and nomographs. Large amounts of such data are given.

The volume is an engineering handbook of particular value to furnace designers and its study would be of value to many furnace users on account of the discussion of the factors involved in obtaining thermal efficiency and on choice of furnaces.

General design, resistance elements, refractories, insulation, pyrometers, control devices, and many details of construction are described and illustrated. The Globar type of resistor and Mo resistors are discussed. Arc and induction furnaces are not considered.

The examples and illustrations include many American as well as German furnaces. The bulk of the book deals with small batch type furnaces, but bright annealing furnaces and continuous furnaces of various types are not neglected.

It is well printed, well bound, and well indexed.

H. W. Gillett (23)-B-

Induction Heating of Heat Treating Furnaces. (Le chauffage par induction des fours à traitement thermique.) V. BARUT. *Journal du Four Electrique*, Vol. 41, July 1932, pages 257-260.

Close temperature regulation can be obtained in heating furnaces using the induction principle by generating the heat in the muffle itself and adjusting the composition of the metallic muffle so as to have its point of demagnetization corresponding to the desired maximum temperature. Further adjustment can be obtained by inserting into the muffle proper, slides which produce the desired changes in the amount of heat generated. Furnaces were built on this principle permitting a close and automatic regulation of quenching practice. A furnace is described in which the point of austenization is indicated. JDG (23)

Furnace Dimensions for Maximum Efficiency. (Ueber die günstigste Ausnutzung lichter Ofenabmessungen.) T. STASSINET. Doctor's thesis, 1932, Technische Hochschule Aachen. Paper, 8 x 11½ inches, 31 pages.

A mathematical study is given of proper dimensions of the interior of furnaces, such as annealing furnaces, in relation to the size, number and manner of loading the pieces to be heated. Increased efficiency of 5 to 10% is claimed in fuel fired and in electric furnaces by the use of proper dimensions and loading. Curves are given for various mathematical functions used in the calculations. The treatment is highly mathematical though based on some tests and records of practical operation over a period of years.

Annealing Furnace for Malleable Iron. *Foundry Trade Journal*, Vol. 46, June 2, 1932, pages 339-340; *Iron & Coal Trades Review*, Vol. 124, May 20, 1932, pages 841-842.

A description of a Hermansen recuperative annealing furnace recently installed at the works of Messrs. Alfred H. Mould & Sons, of Walsall, England. OWE+Ha (23)

Mechanical Furnace for Annealing and Heat Treating of Ordinary and Heavy Plates. (Mechanischer Ofen zum Glühen und Vergüten von Mittel-und Grobblechen.) H. FEY. *Stahl und Eisen*, Vol. 52, June 23, 1932, page 617.

Description of mechanically-operated plate annealing furnace developed by the "OFAG," Dusseldorf, for heat treating heavy plate 8-120 mm. thick weighing up to 12 tons, charged cold or warm. Blast furnace gas with a small amount of coke-oven gas is the fuel; 450,000 Kcal/ton is needed when material is charged cold and 250,000 Kcal/ton when it is warm. Furnace is 20 m. long and 3.4 m. wide, and production runs from 20 to 30 tons/hr., cold or hot charge, respectively. DTR (23)

On Gas Flow in Pusher Furnaces. (Beitrag zur Kenntnis der Strömungsvorgänge in Stossöfen.) ADOLPH BRANDL. *Archiv für das Eisenhüttenwesen*, Vol. 5, Apr. 1932, pages 609-613.

Report of the Heat Section of the Verein deutscher Eisenhüttenleute. The velocity distribution of gases in pusher furnaces agrees thoroughly with the flow of cold gases and liquids. One of the determinations of flame loss gave unexpectedly high values (heat loss above 10%) and showed that the draft and pressure ratios must be watched carefully. The temperature measurements showed a sharp drop in the vicinity of the heating surfaces. The temperature distribution appears to be influenced principally by the cooling conditions; the use of burners on the side of the furnace would remove the cold layers and influence heat transfer favorably. The measured pressure loss due to friction checked with the approximate ratio. The Grum-Grzimailo is not an acceptable theory of the gas flow in the impulse or pusher type furnace; it is generally possible to figure on a complete filling of the furnace cross section. From the study of the draft and pressure ratios it is evident that the holding of the minimum pressure differential or drop between the inside of the furnace and the atmosphere over the entire length of the furnace (heat economy of no small importance) may be attained by the use of a diffusion-like furnace construction, or "Equal Pressure" furnace. DTR (23)

Mixed-Gas Heating for a Pressing Plant Heating Furnace. (Mischgas beheizung für einen Presswerk-Wärmofen.) W. BOETTCHER. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns*, Vol. 1, Dec. 1931, pages 194-200.

The capacity and temperature of a furnace for a varied type of articles could be increased considerably by mixing the blast furnace gas which was the original fuel with Selas gas, a coke gas. The most favorable mixture is determined according to the goods to be heated; diagrams show the relations between mixtures and temperatures obtained, output increased and heat consumption. Ha (23)

Forge Furnaces Improved by Diffusion Combustion. H. M. HEYN. *Steel*, Vol. 90, Mar. 14, 1932, pages 36, 38.

Most forging difficulties due to scaling of steel may be solved by proper control of furnace temperatures and furnace atmospheres. Diffusion combustion provides this control by maintaining the gas and air currents in separate and distinct layers so that combustion proceeds only at the flame boundaries where mixing occurs. The lowermost layer of gas sweeps over the bottom and blankets the work against the effects of air and the products of combustion. As a result, the steel remains unoxidized in the furnace and the total amount of scale formed is considerably reduced. Other benefits of diffusion combustion are rapid heating rates, uniform distribution of temperature and the prevention of the dangers of overheating and burning. JN (23)

Forging Costs Reduced by use of Modern Furnaces. C. L. WEST & R. R. LA PELLE. *Heat Treating & Forging*, Vol. 18, May 1932, pages 315-318; June 1932, pages 373-375, 378.

In a plant producing a 30 lb. steering knuckle, made of SAE 1045 steel, 2 oil-fired, slot-type furnaces were replaced by an 8 ft. hearth diameter, oil-fired, rotary type forging furnace. Other equipment and conditions remained the same. In another plant producing a 45 lb. automotive forging of SAE 1030 steel, 2 large natural-gas-fired, slot-type furnaces were replaced by a gas-fired, continuous, pusher-type furnace of the V-groove hearth type. As a result of these changes fuel cost was reduced about 50%, production increased about 100%, while wages of hammer and press crews were increased. In the first case, actual savings in cost of fabrication was 37% and in second, 41%. Survey of a number of installations of continuous forging furnaces shows production has been increased 40-200%. Reasons for this increase are a continuous supply of thoroughly heated steel, without excessive localized temperatures or excessive scale; improved working conditions; delivery of material at uniform and continuous rate; elimination of overheated and burnt steel; and control of atmosphere. For heating the end of a piece of stock an automatically controlled rotary-type furnace has been developed. The entire furnace rotates. Multi-door batch-type furnaces have been developed for unusual shapes and sizes for intermittent production. A recent installation combines the advantages of the diffusion burner with the use of a non-metallic type recuperator, resulting in very low fuel consumption. MS (23)

For High Purity Melts ..

Free from Contamination

Norton Magnesia Cements

PURITY of melt is important in metallurgical practice. And, to eliminate the refractory lining as a source of contamination many concerns are using Norton Magnesia Cements—lining induction furnaces used for melting ferrous or non-ferrous metals.

Norton Magnesia Cements are made from magnesia that has been fused in electric furnaces at extremely high temperatures. Objectionable impurities are held at a minimum and the resulting product contains as high as 97% of magnesium oxide.

Several varieties of Norton Magnesia Cement are available to meet different furnace conditions. All are extremely resistant to penetration by the melt and to reaction with the slag.

GASES IN METALS (25)

On the Determination of Gases in Metals with Special Reference to the Determination of Oxygen in Iron and Steel by the Hot-Extraction Method. (Zur Bestimmung der Gase in Metallen, besonders des Sauerstoffs in Eisen und Stahl, nach dem Heissextraktionsverfahren.) H. DIERGARTEN. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen,* Vol. 11, 1932, 10 pages.

See *Metals & Alloys,* Vol. 1, Sept. 1930, page 744. Ha (25)

Synthesis of Gas-Metal Compounds by Sputtering. L. R. INGERSOLL. *Journal American Chemical Society,* Vol. 53, May 1931, pages 2008-2009.

Ni sputtered in nitrogen under special conditions gives a dark, somewhat metallic-looking film which shows on X-ray examination a crystal structure distinctly different from that of the pure metal. Compounds of Co and Fe with nitrogen have also been produced, as well as of Ni and H. MEH (25)

A Dark-blue Nickel Oxide. (Ueber ein dunkelblaues Nickeloxyd.) M. CENTNERSZWER & H. ZYSKOWICZ. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 206, June 18, 1932, pages 252-256.

The action of CO, air and O on Ni was investigated. While no effect on Ni-sheet could be stated in the temperature range from 50° to 150° C., Ni-powder showed a distinct change by forming a compound NiO of distinctly blue color; the color is maintained up to 290° C. when it changes into yellow-green. This oxide is soluble in organic acids by heating, but insoluble in alkalies and organic solvents. Ha (25)

The Heats of "Adsorption" of Oxygen on Nickel and Copper Catalysts. W. WALKER RUSSELL & OSBORNE C. BACON. *Journal American Chemical Society,* Vol. 54, Jan. 1932, pages 54-71.

Relatively large amounts of O are rapidly and irreversibly adsorbed on catalytically active Ni and Cu surfaces with considerable evolution of heat. A catalytically active surface, capable of again adsorbing large amounts of oxygen at 0° with only moderately reduced thermal effects, is obtained simply by heating in a suitable temperature range a surface previously poisoned by saturation with oxygen at 0°. Evidence is advanced indicating that heating causes a change of adsorbed O to stable oxide. Evaluation of the activity of Cu catalysts by reaction velocity measurements and by heats of O adsorption and adsorption capacity, indicates that definite relations exist between these properties. MEH (25)

On the Removal of Gases from Aluminium Alloys by Mixtures of Nitrogen and Volatile Chlorides. J. D. GROGAN & T. H. SCHOFIELD. *Institute of Metals, Advance Copy* No. 612, Sept. 1932, 9 pages.

Previous experiments had shown that gases can be removed from molten Al alloys by volatile chlorides. Tests with several Al alloys proved that they can also be removed by chlorides diluted with commercial N. About 0.25 cc. CCl_4/lb. of metal proved satisfactory for small melts. Tensile tests indicated that the degasified alloys had good properties. JLG (25)

Adsorption and Activation of Carbon Monoxide at Palladium Surfaces. HUGH S. TAYLOR & PAUL V. MCKINNEY. *Journal American Chemical Society,* Vol. 53, Oct. 1931, pages 3604-3624.

CO does not reduce palladium oxide and is itself a powerful inhibitor to the reduction of the oxide by H. There is no C formation and no decomposition of CO by palladium below 350° C. The determination of the effect of temperature change upon the amount of adsorption is shown to be a practical method for the investigation of the various forms of adsorption. MEH (25)

Control of the Gases Occurring in Steel. HENRY D. HIBBARD. *Iron Age,* Vol. 129, May 5, 1932, page 1018.

Control of gases in steel may be accomplished by either chemical, physical or mechanical means. The author concludes by stating that in making steel CO is unavoidable but useful, H is unavoidable but harmful, N is probably unavoidable and a hardener. Other gases, CO_2, NH_3 and perhaps others are accidental and in small quantities. Their effects, if any, are small and negligible. VSP (25)

Gases Retained in Solidified Steel or Evolved from It. HENRY D. HIBBARD. *Iron Age,* Vol. 129, Apr. 14, 1932, page 879, Adv. page 18.

Little is known of gases held in solidified steel. They are probably in solution in the metal. Most prolific yield of gas comes from metal when heated in vacuo, that is, under the smallest pressure attainable. When dissolved in acid particularly HCl and H_2SO_4 the gases evolved are (1) H, set free from acid as metal goes into combination, (2) hydrocarbons formed from decomposition of carbides of Fe and (3) any occluded N, CO_2 and CO which may be in the metal. H is manifestly the most harmful of the gases. Mn in bath metal seems to have some solvent power for CO and much more for H. VSP (25)

Thermodynamic Studies of System Iron-Carbon-Oxygen. (Thermodynamische Untersuchungen zum System Eisen-kohlenstoff-Sauerstoff.) E. SCHEIL. *Stahl und Eisen,* Vol. 52, Apr. 21, 1932, page 394.

Brief summary of recent literature on thermodynamics of system Fe-C-O. Apparatus for equilibrium studies of γ-Fe with CO-CO_2 mixtures is shown in diagrammatic sketch. Changes in weight of Fe are definitely related to C changes for constant ratio $\frac{PCO}{PCO_2}$, and are definitely related to O_2 changes for constant ratio $\frac{P^2CO}{PCO_2}$. Reactivity $A^c = \frac{P^2CO}{PCO_2} \times \frac{1}{K}$ is used, although at higher C-concentrations, solution of C does not follow laws of dilute solutions. $\frac{P^2CO}{PCO_2}$ values for C of several workers show good agreement. For C-content in γ-Fe from 0.09% to 3.0%, ratio varies from 2.6×10^3 to 70.5×10^3. Solubility of C in α-Fe at 800° C. was 0.01% C. Solubility of O_2 in γ- and α-Fe, 0.01%. Correlated results on O_2-solubilities do not show good agreement. DTR (25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Low Melting Heavy Metals in Lead Base Bearing Metals. (Über die leichtschmelzenden Schwermetalle in Blei-Lagermetallen.) K. L. ACKERMANN. *Metallwirtschaft,* Vol. 11, May 20, 1932, pages 292-293.

1 5 references. The addition of 5% of Sn, Hg, Bi or Cd to Pb has a hardening effect. The Brinell hardness of pure Pb is 5.7 kg./mm.², with 5% Sn added it is 9.7, with Hg 10.1, with Bi 6.7 and with Cd 19.2. 5% Ti does not alter the hardness. Additions of Hg or Bi to the eutectic alloy 82% Pb, 7% Sn, 11% Sb produce an hypoeutectic alloy, of Tl or Cd an hypereutectic alloy. Additions of Hg to Pb base bearing metals have little influence on the hardness, the elastic limit of compression is increased, but the wearing properties are lowered. Bi has no influence on the hardness of Pb base bearing metals, and decreases the hardness of those containing Ni. Tl has no practical value as an addition to bearing metals. In certain concentrations Cd increases the strength of bearing metals, but if the percentage is too high they become brittle and weaker although they are harder than similar alloys without Cd. Alloy Cast Irons. GERALD S. BELL. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 151-153.

See *Metals & Alloys,* Vol. 3, May 1932, page MA 147. CHL (27)

Ferro-Alloys in the Steel Foundry. R. C. GOOD. *Steel Founder,* Vol. 3, Mar.-Apr. 1932, pages 36-38, 49.

3 The various ferro-alloys are briefly discussed with regard to their effect and alloying conditions. In the foundry ferro-silicon and ferro-manganese are used as scavengers, the former also as a gas solvent. The effects of Cr and some complex alloy combinations on toughness and machineability of cast steel and cast Fe are briefly described. Ha (27)

Improvement of Steel and Cast Iron by the Addition of Zirconium. (Amelioration de l'acier et de la fonte par le zirconium.) PH. GUY. *Aciers Spéciaux, Métaux et Alliages,* Vol. 7, Jan. 1932, pages 12-14.

4 Tests made during recent years proved the fact that Zr added as Zr-Fe-Si alloy improved the properties of cast steel and cast iron. As examples are cited 2 steels; one of 0.61% C, 0.23% Si, 0.62% Mn, 0.015% P and 0.019% S to which was added Zr. The Izod number was increased from 12 to 15.2 due to the addition of Zr. In another steel of 0.16% C, 0.23% Si, 0.65% Mn, 0.146% P and 0.047% S, the Izod number increased from 35.3 to 46 after the addition of Zr. Steels containing 0.10-0.20% Zr, after heat treatment exhibited decided improvement in ductility, resistance to shock, and increase in elasticity. Addition of Zr to white cast iron renders it gray. It is recommended to add to steel a sufficient
5 amount of Zr to form 1/3 of the final Si. Additions of Zr to cast iron vary from 0.10 to 0.35%. GTM (27)

The Influence of Third Metals upon the Constitution of the Brasses. IV. The Influence of Aluminum. (Der Einfluss von dritten Metallen auf die Konstitution der Messinglegierungen. IV. Der Einfluss von Aluminium.) O. BAUER & M. HANSEN. *Zeitschrift für Metallkunde,* Vol. 24, Apr. 1932, pages 73-78; May 1932, pages 104-106.

The preparation of alloys, their treatment, and thermal analyses are described. Numerous sectional diagrams are given combining the results of the thermal and metallographic studies: at 1, 2, 4, 6, 7.7, 9.4% Al; also diagrams
6 for constant Cu content 72.5, 69.8, 64.8, 60.8% Cu; for constant Zn content 15, 20, 25, 30, 35% Zn; for compositions 56.5 to 89.5% Cu and 10.5% Al, for 60 to 85% Cu and 15% Al; also ternary diagrams for the solubility limits of the α, β and γ phases at 800°, 600°, 475° and 410° C. RFM (27)

Influence of Small Additions of Foreign Elements on the Shrinkage, Impact Resistance and Hardness of Refined Zinc. (Einfluss kleiner Zusätze von Fremdstoffen auf Schwindung, Schlagfestigkeit und Härte von Raffinadezink.) O. BAUER & P. ZUNKER. *Mitteilungen der deutschen Materialprüfungsanstalten,*
7 1932, No. 12, pages 183-184.

Condensed. For abstract of original article see *Metals & Alloys,* Vol. 2, Sept. 1931, page 190. HWG (27)

Study of Titanium Cast Iron. (Etude des Fontes au Titane.) J. CHALLONSONNET. *L'Usine,* Vol. 41, Feb. 12, 1932, page 27.

The equilibrium diagram of Fe-Ti in the range of 0 to 2% Ti with about 2.2% C was investigated. 3 zones are distinguished: up to 0.8% Ti a white casting, from 0.8 to 1.3% mottled iron, and higher percentages gray iron. The Brinell hardness reduces in the 2 first zones from 550 to about 200 to increase again to about 300 in the third zone; the pearlite
8 follows approximately the same course while above 1.3% Ti the casting becomes ferritic. Ti and Si which have the same chemical characteristics modify the cast iron in the same manner; both favor the formation of graphite in the solidification and later in the annealing, and both reduce the thermal hysteresis. Ha (27)

The Effect of Nickel on the Properties of Whiteheart Malleable Cast Iron (with Special Reference to "Thin-walled Malleable"). Part II. S. J. E. DANGERFIELD, F. JOHNSON AND E. R. TAYLOR. *Carnegie Scholarship Memoirs, Iron & Steel Institute;* Vol. 20, 1931, pages 65-86.

9 The authors report a study of the effect of Ni on the properties of whiteheart malleable where the Si is 0.53% against 0.65% in the Fe reported on in Part I, these Memoirs, Vol. 19, 1930. Ni content up to 3.23% was studied and the conclusion of Part I regarding improved fluidity, non-impairment of machining quality, and no alteration of fracture with increasing Ni were confirmed. The increase in tensile strength is confined to a shorter range reaching a maximum at 1.3% Ni from which it falls off to a very low value at 3.0% Ni. Elongation falls off with increasing Ni. Bars when sound are capable of 180° bend up 1.0% Ni.
10 Lack of scientific control of melting and annealing operation in most malleable plants is discussed with view of pointing to the greatest need for such control. Laboratory annealing tests while not entirely satisfactory confirmed in general the results of works anneal. Reannealing resulted in a general loss of tensile strength. WLC (27)

Cadmium and Tin in Silver Solders. (Kadmium und Zinn in Silberlöten.) THEWS. *Die Metallbörse,* Vol. 21, May 16, 1931, pages 918-919.

The influence exerted by Cd and Sn on the properties of Ag-solders and chemical analyses of the latter are given.

EF (27)

Influence of Small Additions of Aluminum to Gray Cast Iron. (Influenza della piccole aggiunte di alluminio alla ghisa grigia per getti.) G. SIROVICH. *La Metallurgia Italiana,* Vol. 24, Feb. 1932, pages 83-98.

10 references. Fluidity spirals were cast from an iron of 3.24% total C, 2.30% Si, 1.18% P, 0.08% S, 0.42% Mn, with and without the addition of 0.03% Al. The one without Al showed greater fluidity and the cross section of the spiral was gray throughout. With Al, the surface next the sand was white, with the interior gray, the chilled surface increasing in thickness as the free end of the spiral was approached. Another test was run on iron of about 3.05% total C, 0.70 - 0.80% combined C, 2.30% Si, 1.15% P, 0.10% S, 0.36% Mn to part of which about 0.015% Al was added in two different ways. The spiral without Al ran farther than the previous iron without Al, and showed a little chill on the corners of the triangular cross section, the chill starting to appear at about half way toward the free end. A cast with about 0.015% Al thrown into the ladle as a button, and one in which the button was put in the ladle and the ladle then filled, acted alike, the length of the spiral being less than without Al (and about the same as on the 3.24% iron without Al) and the cross section showed a frame of white iron all the way, the white layer increasing in thickness as the free end was approached. The tips of the spirals cast from metal treated with Al showed a bulge, those without Al did not. The above tests were made on 25 to 40 lbs. of metal cast from a small ladle with some wait after adding the Al. In the second series the temperature dropped from 1330° C. on the first cast (no Al) to 1300° C. on the third (with Al). Another series of tests was then run, all cast at 1335° C. (a) without Al addition, (b) adding about 0.01% Al to a 1100 lb. ladle of iron by placing the Al in the cupola spout and taking out a small ladle full from the large ladle, the small ladle having been heated by dipping it in the large ladle, (c) adding the Al to the large ladle, and waiting 5 minutes before dipping out the small ladle. The spiral in (b) ran nearly as far, and in (c) farther than in (a), and only showed a trace of chill on the corners of the triangular cross section near the free end. This last series of three tests was then repeated, save that the Al was added to the large ladle and using a pouring temperature of 1320° C. Here there was no trace of chill on the Al-treated spirals and the Al-treated spirals were longer than the un-treated one. It is concluded that the addition of not over 0.01% Al and the allowance of a few minutes for the Al to act before pouring, improves the fluidity of the iron. Higher Al tends to produce chill. Photos of the spiral, macrographs of the cross sections at different points along the spiral, and micrographs of the structure are shown. See also *Metals & Alloys,* Vol. 3, June 1932, page MA 188.

HWG (27)

Effect of Antimony on the Mechanical Properties of a Bearing Bronze. C. E. EGGENSCHWILER. *Bureau of Standards Journal of Research,* Vol. 8, May 1932, pages 625-634.

A study was made of the effect of additions of Sb (from 0-0.58%) upon the Brinell hardness, the structure, the Izod impact value, the deformation under pounding, and the broaching properties of a bearing bronze containing 80% Cu, 10% Sn and 10% Pb. In general, increasing the Sb content from 0-0.59% had no effect on the broaching properties nor upon the distribution of the Pb particles throughout the Cu-Sn matrix. There was a slight tendency toward an increased size of the areas of the hard δ constituent with the higher Sb content. Additions of Sb lowered the Izod impact value. The deformation under pounding was markedly lowered with the first addition of Sb, reaching a minimum at 0.2% Sb. Higher Sb additions tended to increase the deformation. The addition of Sb up to about 0.2% slighfly increased the Brinell hardness of the alloy, but further additions of Sb, up to 0.58%, caused little or no further change in hardness. WAT (27)

The Influence of Small Amounts of Admixture in Metals. (Ueber den Einfluss kleiner Beimengungen in Metallen.) W. FRAENKEL. *Zeitschrift für Metallkunde,* Vol. 23, Aug. 1931, pages 221-224.

A review. The following subjects are briefly discussed: the available degrees of purity of various metals; the accuracy of analytical methods in determining small amounts of admixed elements; the effect of small amounts of admixed elements upon mechanical properties, recrystallization, electrical conductivity, diffusion, reaction velocity, corrosion; deoxidation and gases in metals. RFM (27)

Cast Irons with Higher Nickel Additions. A. B. EVEREST. *Foundry Trade Journal,* Vol. 46, Mar. 24, 1932, pages 193-194; Apr. 7, 1932, pages 217-218, 226.

In the first section of the article very complete reference is made to the subject of martensitic cast irons and heat-treatable cast irons. The effects of tempering on certain Ni alloys are dealt with in some detail. In the concluding section of the paper the physical properties of austenitic cast Fe are dealt with. OWE (27)

Catalysis and Photoconductors. F. H. CONSTABLE & A. F. H. WARD. *Transactions Faraday Society,* Vol. 28, May 1932, pages 497-508.

New results and known information are given for binary mixtures of Se with Ag; Th; Bi; Pb; Hg; Zn; Cu; Fe. Of these Fe decreases the dark resistance and light ratios (current in the light; current in the dark); Zn and Pb are indifferent in effect; Th, Bi, Cu, Hg, Ag, increase the dark resistance and light ratios. Light ratios are higher at lower annealing temperatures. The addition of any of these substances to Se does not increase the median value of light ratios for a given resistance to a higher value than would correspond to that of a pure Se film of the same dark resistance. These foreign bodies play little part in assisting or retarding the ejection or recombination of electrons under the influence of light, but they influence the chemical constitution of the crystalline light sensitive mass. PRK (27)

INSTRUMENTS & CONTROLLERS (28)

The Application of Electron Tubes in the Steel Industry. D. W. DEAN. *Iron & Steel Engineer,* Vol. 9, Mar. 1932, pages 124-128.

1 The types of electron tubes which have found industrial applications are the phototube, the three-element thermionic tube, and the grid-glow tubes with neon or mercury filling. Their characteristics are briefly explained and applications, especially in steel mills, as relays, controls, etc., described. The possibilities of this kind of equipment, and a list of possible further extension of its use are discussed. Ha (28)

The Settling-Elongation Meter. (Der Setzdehnungsmesser.) A. U. HUGGENBERGER. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 76, Apr. 23, 1932, pages 417-418.

2 After the completion of a structure, changes often take place during the period of settling which it is important to supervise. An instrument is described which can be used for the continuous measurement of the elongations or deformations going on in course of time; it is similar to a lever gage. Several applications are described. Ha (28)

Optical Measurement of Fine Wire. A. C. BLACKALL. *Wire & Wire Products,* Vol. 7, July 1932, pages 230-237.

3 One of the difficulties of measuring very fine wires is the provisional deformation in the very process of measurement by mechanical devices. This trouble has been eliminated by an optical arrangement by which the wire is placed or drawn between a system of lenses and the diameter is read by the position of a prism. The method of calibration of the arrangement is described. The diameters as determined with the apparatus agree with the true value generally to within ± 0.00005". Ha (28)

High-Temperature Control: Photoelectric-Tube Pyrometry. LEWIS R. KOLLER. *Industrial & Engineering Chemistry,* Vol. 23, Dec. 1931, pages 1379-1381.

4 A photoelectric tube apparatus has been developed by means of which it is possible to control furnace temperatures from 1000° C. upwards to within 10°. An important advantage of this device is that it can be applied to high temperatures or to atmospheres which would be destructive to thermocouples or resistance thermometers. MEH (28)

Photocell Control of Temperature. W. P. KOECHEL. *Electronics,* Vol. 4, May 1932, pages 170, 182.

An arrangement of temperature control of 4 filament-coating ovens by means of a photo cell is described. Ha (28)

Temperature Measurement of Molten Cast-Iron. (Temperaturmessungen an flüssigem Gusseisen). J. MOELLER. *Die Messtechnik,* Vol. 7, Apr. 1931, pages 93-96.

5 After a discussion of the importance of the temperature measurement of the liquid cast-Fe the 3 principal measuring methods are described and compared: thermo-electrical pyrometer, total radiation pyrometer, partial radiation pyrometer; the latter type is considered to be the most practical. As an example of the latter the "Pyropto" of Hartmann & Braun is described. From measurements with an instrument of the latter type the following emission coefficients of Fe have been found: Fe, solid, polished, 0.45; Fe, liquid, bright, 0.40; Fe, solid, in air (below 137° C.) 0.90; Fe oxide 0.90. lead bath (slag) about 1.0; salt baths, about 0.50. These figures give the difference between the radiation of a black body and the not black body. A diagram is given from which the corrections for temperatures up to 2000° C. can be taken directly. See also *Metals & Alloys,* Vol. 3, May 1932, page MA 148. Ha (28)

The Photo-Electric "Eye" in a Steel Mill. *Machinery,* Vol. 38, Nov. 1931, page 206.

A photoelectric cell is used at the plant of the Bethlehem Steel Co., Lebanon, Pa., to actuate the mechanism for cutting the bars. When the end of the bar passes over the cell, the bars are cut. The length is varied by moving the cell. RHP (28)

Automatic Remote Gas Pressure and Volume Limit Control. *Iron & Coal Trades Review,* Vol. 124, Feb. 12, 1932, page 280.

7 An electro-hydraulic regulating arrangement for the distribution of a fluctuating gas supply to the various sections of a large works is described. The gas pressure on a diaphragm is held in balance by a weight and a spring acting on the levers for the control of the required gas pressure; the movement of the diaphragm in one or the other direction closes energizing circuits for electromagnets. Ha (28)

Some Notes on the Application of Direct Acting Thermostats to Industrial Appliances. *Gas World,* Industrial Gas Supplement, Vol. 96, Mar. 19, 1932, pages 17-18.

8 Deals with the advantage in having automatic temperature control for the various industrial processes with thermostatic control applied at very low cost. The particular applications referred to are its use in the hardening of Al where the action of the thermostat is steady and will turn off the gas before the highest temperature needed is reached, in the drying of cores in iron foundries, and in washing machines for finished castings where the hot water used in a plating shop is regulated. MAB (28)

Electrical Acidity Detector and Flow Controller. *Engineering & Mining Journal,* Vol. 133, Aug. 1932, page 426.

9 2 automatic signals have been developed by the electrical department of the Inspiration Copper Co. which aid in the operation and maintenance of equipment at the leaching plant. The first signals the presence of acid in the return condensate from the heat transfer division. A small electrolytic cell, operating on a.c., in the flow of the condensate from the vacuum pumps to the condensate storage tanks removes the acid. Pb electrodes are spaced with 4½" centers and a 1000-ohm Benjamin Telecode relay is connected in series to these. 1 part of acid is indicated in 1000 and the presence of acid in the condensate is indicated by signal lights, while a horn warns of exceptional acidity. A second electrical installation determines the rate of solution flow through a launder. 5 electrodes of varying lengths are suspended from a wooden holder bolted to the top of the launder and as they become immersed in the solution, circuits are established that light signal lamps at the main pump stations, indicating the various solution levels. An alarm circuit operates on the high solution level. WHB (28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

The Modulus of Elasticity of Steel at High Temperatures. E. Honegger. *Brown Boveri Review,* Vol. 19, July/Aug. 1932, pages 143-147.

The tests have shown that at high temperatures the modulus of elasticity is smaller the longer the time for which the load is applied. The dependence of the modulus of elasticity on the time makes it necessary to take into account in calculations the variation of the loading with time. MAB (29)

Heat Resistant Steel Containing Chromium, Nickel, Aluminum and Silicon. (Hitzebeständiger Stahl durch Legierung mit Chrom, Nickel, Aluminium und Silizium.) Wilhelm Oertél & Alexander Schepers. *Stahl und Eisen,* Vol. 52, May 26, 1932, pages 511-513.

To produce a steel of fine-grained structure, highly heat resistant, and highly resistant to scale loss on ignition, increasing amounts of Ni were made to 26 different steels, containing C from 0.18 to 0.38%, and varying amounts of Cr, Si and Al. The tensile strength and elongation were determined at 700°, 900° and 1000° C., and the ignition loss at 900°, 1000°, 1100° and 1200° C., together with an examination of crystal structure. Results were tabulated and the most suitable alloy steel for the purpose contained 18% Cr, 8% Ni, 0.5 to 1.0% Al and 2 to 2.5% Si. DTR (29)

Tensile Properties of Rods and Wires at Low Temperatures. (Festigkeitsprüfungen an Stangen und Drähten bei tiefen Temperaturen.) F. Pester. *Zeitschrift für Metallkunde,* Vol. 24, Mar. 1932, pages 67-70.

The tensile properties of bars of Cu, bronze, Al, Aldrey and steel were determined at temperatures of +20°, −20°, −60°, −77° C. Tensile curves at low temperatures are given and the changes in tensile strength, yield point, elongation and reduction in area over this range in temperature are expressed in graphs. In general the tensile strength increases with decreasing temperature, the elongation increases, and in some cases the reduction in area also increases. RFM (29)

Study of a C-Cr-Mo Steel at Room and High Temperatures. Its Overheating and the Correction of the Effects of Overheating. (Etude d'un acier au C-Cr-Mo a la temperature ordinaire et a hautes temperatures. Sa surchauffe et sa regeneration.) A. C. Prulière. *Revue de Métallurgie,* Vol. 29, Jan. 1932, pages 34-44; Feb. 1932, pages 93-101; Mar. 1932, pages 156-163.

43 references. A comprehensive study of a steel containing: 0.60 C, 0.40 Mn, 0.25 Si, 0.11 P, 0.004 S, 1.60 Cr, 0.22 Mo at room temperature, in the range 425°-1000° C., and after overheating. Mechanical, metallographic and physical properties were studied. Overheating can be corrected by an air quench from 950° C. following a long soaking. JDG (29)

Research on Vanadium Steels and Their Significance in Heat Technic. (Erforschung der Vanadiumstähle und ihre Bedeutung für die Wärmetechnik.) Br. Schulz. *Brennstoff- und Wärmetechnik,* Vol. 13, Jan. 1931, pages 7-10.

Discovery, commercial utilization and properties are briefly summed up. The influence of V on the metallography and physical properties of steels is considered at length, mainly referring to articles by Guillet, Vogel and Tammann, William and Barness, Sperling, Moldenke, Oberhoffer and coworkers, and Prömper and Pohl. The balance of the paper refers to information on the utilization of V steels for the construction of super-heater units, blades of steam and gas turbines as well as parts of water turbines. Concludes with a comparison between CrV and CrNi steels. EF (29)

Tensile Tests on Welded Rods at Elevated Temperatures. (Warmzugversuche an Schweissen.) H. A. Horn. *Zeitschrift für Schweisstechnik,* Vol. 21, Oct. 1931, pages 241-245.

Data from tensile tests at 20°, 150° and 250° C. on gas-welded and electro-welded 6 mm. rods turned from big seams of welded mild steel are given. The gas-welded test pieces proved to be decidedly superior to the electro-welded samples. The elongation decreases somewhat with rising temperatures, whereas the strength materially increased. The use of special coated electrodes in electro-welding is urged in order to improve its efficiency. In the critical discussion of the results, the importance of taking into account the properties of the transitional regions between seam and virgin metal is stressed, since the present tests refer only to the seam itself. Nevertheless, the high yield point and favorable elongation values of gas-welded seams are of primary significance in boiler construction. EF (29)

Heat Treatment of Bolts has Improved Modern Engineering Practice. F. O. Kichline. *Heat Treating & Forging,* Vol. 17, Nov. 1931, pages 1042-1045.

This article was published in *Iron Age,* Vol. 128, Oct. 22, 1931, pages 1058-1060 and in *Steel,* Vol. 89, Oct. 26, 1931, pages 31-33, 38. See "New Uses for Bolts Demand Higher Standards of Manufacture," *Metals & Alloys,* Vol. 3, July 1932, page MA 227. MS (29)

Japanese Discuss Many Aspects of Metal Science. Correspondence from K. Honda, Sendai, Japan. *Metal Progress,* Vol. 21, Mar. 1932, pages 72, 92.

Recovery of Gold and Silver from Graphite and Non-Graphitic Waste. J. N. Plaksin & N. L. Zhurlov. *Tsvetnuie Metallui*, No. 9, Sept. 1931, pages 1156-1179.

Curves are plotted showing the effect of time and concentration of cyanide solutions on the recovery of Au and Ag from graphite wastes. The character of the curves depends on the NaCN content of the solution. The curves show rapid precipitation of Au from solution on account of the adsorption of the complex cyanide by graphite. Maximum extraction of Au is attained in less than 18 hrs.; after this the recovery decreases. The rate of deposition of Ag from the solution is considerably less. Recovery is the net result of the rate of solution of metals in the cyanide solution and the rate of adsorption by graphite, both depending on the concentration of the solution. As the most practical method of extraction of Au and Ag from graphitic waste the following are recommended: (1) Cyaniding in the presence of kerosene or pine tar to prevent adsorption. (A recovery of 99.03% Au and 94.93% Ag was obtained by this method.) (2) Cyaniding followed by treatment with Na_2S solution. (3) Igniting followed by amalgamation, or by amalgamation with Au amalgam in the presence of $CuSO_4$ or in Cl water. For lean non-graphitic waste 2 methods can be applied: (1) Amalgamation with simultaneous or subsequent cyaniding. (92.2% recovery Au and 83.82% Ag was obtained.) (2) Pyrometallurgical extraction from a concentrate obtained by preliminary table or flotation concentration. Table concentration gave higher recovery (80%) than flotation and should be preferred. Further treatment consists of Pb fusion and cupellation. BND (30)

The Recovery of Gold from the Ore of the Night Hawk Lake Mining Co., Ltd., Night Hawk Lake, Ontario. A. K. Anderson. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 130-135.

Cyanidation of a porphyry containing pyrite assaying Au 0.14-0.17 oz. and Ag 0.03-0.07 oz./ton gave highest recoveries (97%) with a cyanide consumption of 0.60 lb./ton of ore. Results by flotation and amalgamation alone and in combination are given. AHE (30)

The Recovery of Gold from the Ore of the Parkhill Gold Mines, Limited, Wawa, Ontario. A. K. Anderson. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 154-158.

A siliceous Au ore assaying 0.99 oz./ton gave recovery of 77.7% by amalgamation, 94.1% when followed by cyanidation. Flotation recovered 88%. Cyanidation of the ore ground to minus 200 mesh recovered 98% of the Au. AHE (30)

Experimental Tests on a Sample of Tailings from the Mill of the Argonaut Gold Mines, Limited, Larder Lake, Ontario. J. S. Godard. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 110-112.

A tailing assaying Au 0.115 oz./ton, Cu 0.19%, and Fe 9.93%, the remainder mainly SiO_2 gave a higher recovery by cyanidation (85%) than flotation. AHE (30)

Precipitation and Cyanide Recovery Process Developed by General Engineering Company. R. M. P. Hamilton. *Engineering & Mining Journal*, Vol. 133, Jan. 1932, pages 53-54.

An efficient, cheap method of recovering the cyanide and precious metals (if any) in barren solutions fouled by contact with cyanide-consuming ores is described. A flowsheet is shown for a precipitation and cyanide recovery plant and a table for precipitation equivalents. The process is cyclical, and requires simply the H_2SO_4 needed to regenerate the HCN from the Zn $(CN)_2$ precipitate, plus the little necessary for precipitation of Au and Ag with Zn, and the lime necessary to "fix" the regenerated HCN. Over 95% of the solutions going to the recovery plant may be re-used as fresh water in mill circuits. WHB (30)

Cyaniding Low-Grade Gold Ore. Chas. Volney Averill. *Chemical Engineering & Mining Review*, Vol. 24, Dec. 5, 1931, pages 87-91.

A description is given of the cyanide plant for the treatment of gossan at the Mountain Copper Co.'s works, Shasta Co., California. Gossan ore, hitherto not considered amenable to cyaniding, is successfully treated in a plant handling 550 tons per day at a cost for mining and milling of $.85/ton. The standard Merrill-Crowe vacuum process of precipitating Au from solution is employed. WHB (30)

Cyanidation: An Historical Note. B. K. Read. *Canadian Chemistry & Metallurgy*, Vol. 16, Jan. 1932, pages 30-31.

The failure of salt treatment is pointed out, the McArthur-Forrest process is outlined, and the rise in cyanide production noted. WHB (30)

Development of the Leaching Operations of the Union Miniere du Haut Katanga. Archer E. Wheeler & H. Y. Eagle. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 459, Feb. 1932, 37 pages.

Developments at the Union Miniere since 1914 are reviewed, with special reference to the development of large scale leaching methods. The Cu can be dissolved readily by dilute H_2SO_4, but percolation through the crushed ore is slow. Therefore leaching by all agitation is desirable. Plants and flow sheets are described. Practically all of the ores, averaging 6.5 to 7.0% Cu, are oxidized. The ore is leached in Pachuca agitators, and the Cu extracted from the solution electrolytically. The cathode is refined at the smelter. 4 references. JLG (30)

Milling Practice of the Kirkland Lake Gold Mines (Ltd.), Kirkland Lake, Ontario. John Dixon. *United States Bureau of Mines Information Circular* No. 6508, Sept. 1931, 13 pages.

During 1930, heads to the mill assayed $11.38 of Au/ton of ore, of which $10.16 was recovered by cyanidation at a cost of $1.389/ton of ore. Details of costs and analyses of solutions, tailings, etc. are given. AHE (30)

Amalgamating and Cyaniding on Siscoe Island, Quebec. C. O. Steel. *Engineering & Mining Journal*, Vol. 133, June 1932, pages 319-322.

A simple arrangement at the discharge end of the ball mills, followed by amalgamation, recovers 78.5% of the Au in the ore. Blankets in the circuit recover an additional 7.0%. Cyanidation recovers 13.0%. Results of tests are tabulated and a flowsheet of the mill of the Siscoe Gold Mines is shown. WHB (30)

REDUCTION METALLURGY (31)

Overblowing in Blast Furnace Practice. W. McConnachie. *Iron & Steel Industry & British Foundryman*, Vol. 5, Mar. 1932, pages 233-234.

Overblowing destroys more than the usual quantity of cyanides and therefore affects the fuel economy in a blast furnace. CHL (31)

The Thermal Action of Sulphates in the Superroasting of Zinc Blendes. (Sur l'Action Thermique des Sulfates dans le Supergrillage des Blendes.) R. Palante. *Chimie et Industrie*, Special Number, Mar. 1931, pages 464-474.

A study is made of the relative effects of the various reactions in the roasting, and especially the super-roasting, of blendes, and of the exact thermal effect of the presence of $ZnSO_4$. Includes discussion. MAB (31)

Recent Improvements in the Greenawalt Sintering Apparatus. J. Tornblad. *Iron & Steel Institute, Advance Copy* No. 14, May 1932, 10 pages.

Improvements that have increased life of the apparatus and have enabled greater production are described. JLG (31)

The Reducibility of Crusted Coke and the Production of a Low-Carbon Forgeable Iron in the Cupola Furnace. (Ueber die Reduktionsfähigkeit von Ueberkrustetem Koks und die Herstellung eines Kohlenstoffarmen schmiedbaren Rinneneisens im Giessereischachtofen.) E. Piwowarsky. *Mitteilungen aus dem Giesserei Institut der Technischen Hochschule zu Aachen*, Vol. 2, Oct. 1931, 4 pages.

The reaction with CO_2 between 900° and 1100° C. of coke uncoated and of coke coated or impregnated with lime paste or milk of lime was studied. A larger amount of CO was produced from coke treated with lime than from the untreated coke. These results are greatly dependent on the air conditions in the cupola furnace, temperature and time of contact between Fe and coke charge. The production of a low-C Fe in the cupola requires a large amount of air, the blast tuyeres should be numerous and must distribute the air uniformly; eventually 2 rows of tuyeres should be arranged. The air preferably is preheated or even enriched by O, and the melt should be made in properly determined height of the coke charge. Further, high temperatures should be employed in order to accelerate the burning of the coke at a minimum of coke charge and with no less than 160 $m.^3$ air/min./$m.^2$. Fe with 1.6 to 1.8 C has been obtained in this manner. Ha (31)

The Semi-direct Production of Nickel Steel from Sudbury Ore. T. W. Hardy & H. H. Bleakney. *Canada Department of Mines, Mines Branch, Memorandum Series* No. 54, Mar. 1932, 16 pages; *Metal Progress*, Vol. 21, May 1932, pages 69-70.

Cu was removed from a disseminated Cu-Ni-Fe ore from the Falconbridge mine by flotation to give a concentrate analyzing Fe 48.02, Ni 3.52, Cu 0.50, S 31.75 and insoluble 9.20%. This concentrate was roasted to give a calcine analyzing Fe 54.96, Ni 4.07, Cu 0.49, S 0.21 and insoluble 10.18%. A reducing roast (city gas over calcine at 1100° F. in a rotary retort for 2 hrs.) followed by wet magnetic concentration (Grondal) gave a concentrate analyzing Fe 61.70, Ni 4.45, Cu 0.42, S 0.16 and insoluble 5.99%. After sintering, the material is metallized by any of the sponge-Fe processes. Using the product of the oxidizing roast, a mixture of 50 lbs. oxide, 18.25 lbs. bituminous coal and 12.0 lbs. lime was heated (electrically) in a rotary retort at 1750° F. for 3 hrs. to give a product analyzing Fe 46.60, Ni 3.65, Cu 0.36, and S 0.66%. 10 passes over a Stearns drum-type magnetic separator gave a concentrate analyzing Fe 72.80, Ni 6.00, Cu 0.58, and S 0.08% and tailing (40.30%) containing Fe 7.80, Ni 0.17, Cu 0.03 and S 1.53% for recoveries of 93.48% of the Fe, 98.08% of the Ni and 96.11% of the Cu with rejection of 92.79% of the S. Smaller-scale tests on the magnetic concentrate of the ore gave a sponge containing 89.67% metals. Briquetted sponge was used in making 5 different Ni steels; details of the charges and analyses of ingots are given. Recoveries of Ni and Cu are almost perfect; Fe recovery is more than 90%. All ingots rolled well without evidence of red shortness. Mechanical properties are given tabularly in comparison with steels of similar composition made with metallic Ni and show that the 2 are comparable. AHE+WLC (31)

Nickel-Copper Smelter at Falconbridge. *Canadian Institute of Mining and Metallurgy, Transactions* (in Bulletin 243), 1932, pages 315-322.

The Falconbridge plant is described. The coarse ore is smelted without roasting in a blast furnace. The necessary basic flux is furnished by converter slag plus enough limestone to give 5-6% CaO in the furnace slag. The low-grade matte produced (9.5-11% Ni and Cu) is blown-up in the converter to almost complete removal of Fe (less than 0.2%), using fine ore to provide necessary SiO_2 for fluxing. AHE (31)

Smelting at Rounskar, Sweden. A. G. Paul Palen. *Engineering & Mining Journal*, Vol. 133, June 1932, pages 339-342.

An outline is given of smelting operations at this plant, completed in 1930. The ore is a mixture of arsenopyrite, calcopyrite, and pyrite with admixtures of small amounts of other minerals bearing Au, Ag, Pb, Zn, and Sb. WHB (31)

The Metallurgy of Zinc. Samuel Field. *Metal Industry*, London, Vol. 40, Jan. 15, 1932, pages 78-80.

Processes of extraction of Zn are described. From low grade ores, Zn is recovered as ZnO in the comparatively new Waelz process. PRK (31)

Electrothermic Zinc. A. Walter. *Transactions Electrochemical Society*, Vol. 59, 1931, pages 87-94.

Includes discussion. See *Metals & Alloys*, Vol. 2, June 1931, page 123. (31)

The Blast Furnace Turbo Blowers of the Russian Steel Plants Magnitogorsk and Kusnezk. (Die Hochofenturbogebläse für die russischen Eisen- und Stahlwerke Magnitigorsk und Kusnezk.) M. Schattschneider. *B B C Nachrichten*, Vol. 19, May/June 1932, pages 41-48.

After briefly discussing the production capacities of the 2 new Russian steel plants, the turboblowers for the blast furnaces are described in detail and illustrated. GN (31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Pipe Line Protection. F. A. Hough. *American Gas Journal.* Vol. 137, Aug. 1932, pages 11-13.

Soil survey made with Shephard Earth Resistivity Meters (soil rods) indicate areas where pipe protection is needed and extent of protection necessary. Details of this method are described in *American Gas Journal,* Apr. 1931, page 34. Protective coatings will be either: (1) double coal tar coatings with an asbestos felt wrapper; or (2), asphalt primer, hot coat of blended asphalt, rag felt wrapper, hot coat of blended asphalt, rag felt wrapper and Kraft paper. Protective coatings will be supplemented by electrical drainage or cathode protection whereby current will be drained from the pipe to the soil by an especially designed electrode so that the potential of the protected portions will be below that of the soil and corrosion at pin holes or bruised spots of the coating will be prevented. CBJ (32)

Enameling with Spray Guns. (Auftragen mittels Spritzapparaten.) M. Becker. *Emailletechnische Monatsblätter,* Vol. 8, June 1932, pages 43-44.

Discussion of the advantages of spray guns for enameling. GN (32)

Experiences with Bituminous Coatings for Rust Protection. (Erfahrungen mit Bitumenanstrichen als Rostschutz.) Nils Buer. *Bautechnik,* Vol. 10, July 29, 1932, page 430.

Abstract of a paper by J. Gram in *Meddeleser fra Norges Statsbaner,* Oslo, Feb. 1, 1932, in which the experiences of the Norwegian railways with bituminous coatings are reported. GN (32)

The Determination of the Cracking Strength of Enamels on Iron Articles. (Die Ermittlung der Abspringfestigkeit von Emaillüberzügen auf eisernen Gegenständen.) E. Franke. *Sprechsaal für Keramik, Glas, Email,* Vol. 65, May 5, 1932, pages 328-329.

The various failures of enameled iron articles are first discussed, the possibilities of mechanically testing enamels are then described. The Herbert cloudburst test is found to be most adaptable. The uniformity of the testing conditions is emphasized for obtaining comparable results. GN (32)

The Effectiveness of Rust Prevention Paints. (Zum Wirkungsgrad von Rostschutzfarben.) A. Foulon. *Farbe und Lack,* Mar. 18, 1931, page 142.

Among the various rust protection paints only those metal oxides and metal salt additions serve their purpose which are electro-positive to Fe. The ground pigment most suitable for the passification of Fe, is red lead. For outer surface coatings, lead white and zinc oxide are employed. Special light protection is secured by red Fe-oxide and iron mica paints. EF (32)

Effect of Lead-Joint Heat on Bituminous Pipe Lining. Elson T. Killam. *Engineering News-Record,* Vol. 109, Aug. 18, 1932, pages 199-200.

Tests show that bituminous enamel linings in cast Fe pipes are not damaged seriously by the heat of the Pb used as joining material if the temperature of the Pb is not materially above its melting point. Other factors having influence are: atmospheric conditions and air temperature, grade of enamel, size of pipe, depth of Pb joint, class or thickness of pipe and the distance from melting pot to the joint. CBJ (32)

Steel Tubes with Centrifugally Cast Concrete Linings in the Pipe Line System of the City of Dresden. (Stahlrohre mit eingeschleuderter Betonschicht im Dresdner Wasserrohrnetz.) Schemel *Die Röhrenindustrie,* Vol. 24, Mar. 26, 1931, pages 77-78; Apr. 9, 1931, page 89.

Experiences gained on previously used cast Fe and centrifugally cast pipes are reviewed and economical and technical viewpoints, when largely extending the municipal pipe line system are considered at length. The critical discussion on 6 different materials proposed is made. The final choice were wrought Fe pipes with a centrifugally cast concrete lining. Problems referring to the smoothness of the linings, joining of the pipes and the drilling of holes into it did not offer unsurmountable difficulties. The maximum length of the tubes was 14 meters and the maximum inside diameter was 1.50 meters. In case of the maximum diameter a concrete shell was employed, the over-all wall thickness amounting then to 10 cm. Asbestos cement was employed for joining the outside concrete shell. A testing tube was started in 1926 and after 3 year's operation, it was found to be in a perfect state. Only a thin chalk layer had been formed at the inside. Tests in the Technische Hochschule Dresden disclosed that the loss in pressure is 12% lower than in cast Fe pipes. This value certainly improves to 13-20% after being some time in service. Due to incrustations, pressure losses of 100% are encountered in cast Fe pipes. The paper was presented at the 77th General Meeting of the Gas und Wasserfachmänner, 1931. EF (32)

Heat Resisting Paint and Rust Preventative. *Iron & Coal Trades Review,* Vol. 124, Apr. 8, 1932, page 601.

"Kemick" is a paint with a liquid and volatile content which spreads it evenly on the surface and holds the pigment in place before heating. Under heat, the paint decomposes, the volatile matter evaporates and chemicals are liberated which react on the surface and become part of it and neutralize rust producing agents. Ha (32)

Loss of Heat in Pipe Lines Laid in the Soil. (Der Wärmeverlust von Rohrleitungen im Erdreich.) I. S. Cammerer. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Feb. 1932, pages 29-34.

Investigations were made on 2 pieces of pipe laid in the soil. The humidity of the soil, the range in temperature, and the extent of soil affected were taken into consideration. Insulation on the pipes was of uniform thickness. The loss of heat in non-insulated pipes was also determined, as well as the heat coefficient of the soil. The loss of heat in the pipes was calculated by means of the original equations for a heat current passing through cylindrical surfaces, with the zone affected taken as 3 m. In sandy soil the coefficient of heat conduction was found to be 1.0. MAB (32)

Non-tarnishing Silver. (Anlaufbeständiges Silber.) E. Raub. *Die Umschau,* Vol. 36, Jan. 3, 1932, pages 84-85.

Article discusses measures for preventing the tarnishing of Ag. The effect of alloying metals was not entirely satisfactory. Electroplating with Cr and metals of the Pt-group is effective. However color and metallic luster differ from pure Ag. The disadvantages inherent to coatings of lacquer, celluloid, collodium, etc., are critically reviewed. Attention is called to a novel coating method developed in the Forschungsinstitut für Edelmetalle, Schwäbisch-Gmünd. The chemical composition of the coating is not stated. EF (32)

Protection of Iron Against Rust. (Wie schütze ich Eisen vor dem Rosten?) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 12, 1932, pages 239-241.

Detailed discussion of the procedure to be followed in the Atrament coating process recently developed by the German Dye Trust. (1) cleaning of the casting, (2) the atramenting process, (3) subsequent treatment. The composition of Atramentol is not given, but it is stated that the surface to be coated is covered with a layer of phosphate by chemical means at temperatures of 98° C. To further increase the corrosion resisting properties the parts are finally blackened with Atrament black (W, S or L). Mixture W is soluble in water, mixture S is soluble in alcohol, the concentrations of the solutions can be chosen according to purpose. Mixture L is delivered ready for use. Any paint or lacquer coating or enamel can be used on the Atrament coating. GN (32)

Evaluating Lacquer Finishes. J. A. Reinhardt & E. A. Woelfel. *Metal Industry,* N. Y., Vol. 30, May 1932, pages 192-194.

Taken from *Monthly Review of American Electroplaters' Society,* April 1932. Some practical tests are described in detail which can be carried out without special laboratory equipment. These tests include determinations of the following: film-building and hiding power, drying qualities, color and luster, manipulation, resistance to perspiration, flexibility, adhesion and aging, humidity cabinet, hardness and resistance to abrasion. PRK (32)

Determination of Water Permeability of Paint Coatings. (Nachweis der Wasserdurchlässigkeit von Anstrichen.) H. Wagner. *Korrosion und Metallschutz,* Vol. 8, Mar. 1932, pages 66-68.

The chemical (Jäger) and galvanic testing methods (Ragg, Hermann, Metzger) for water permeability of paint coatings are critically discussed in the introduction. The author's method is based on the electromotive series used for detecting permeable spots in paint coatings. A $CuSO_4$ solution is applied for sheet Fe and $CdSO_4$ for galvanized Fe. Around the pores metallic Cu and Cd respectively are precipitated. The effect is very distinct and a microscope can be dispensed with in most cases. The reaction discussed can be applied for (A) testing the permeability of coatings on a metal carrier and (B) in laboratory tests on water permeability with respect to binding agents and paint coatings before being used. EF (32)

Paints for Ships. Henry Williams. *Industrial & Engineering Chemistry,* Vol. 23, Dec. 1931, pages 1340-1343.

The general question of painting ships, the need for doing so, and the various causes that lead to deterioration of ships' structure are discussed, as well as several classes of paints that present the most difficulties, and present problems to be solved by the paint technicians. MEH (32)

Suggestions for the Use of Lacquer Capable of Standing Punching in the Metal Industry. (Hinweise für die Verwendung stanzfähiger Lacke in der Metallindustrie.) Freitag. *Oberflächentechnik,* Vol. 9, June 7, 1932, page 113.

Nitro lacquers are mostly used for punched articles; they should adhere tightly to the metal and be sufficiently elastic. Points to be observed in the composition of the lacquer and treatment of the sheets are briefly pointed out. Ha (32)

Increasing Opacity in Cryolite Enamels. (Verstärkung der Weisstrübung in Kryolithglasuren.) *Emailletechnische Monatsblätter,* Vol. 8, July 1932, page 53.

It is advantageous to use besides cryolite other cheap darkening compounds such as alumina, phosphate, metal oxides, etc. It must be borne in mind, however, that white enamels supersaturated with such compounds do not have luster. A new compound is the "Deckborolith" which is melted together in white enamels and which increases the opacity without affecting the luster. GN (32)

Cast Iron Pipe Linings Prove Value. *Water Works & Sewerage,* Vol. 79, June 1932, pages 204-205.

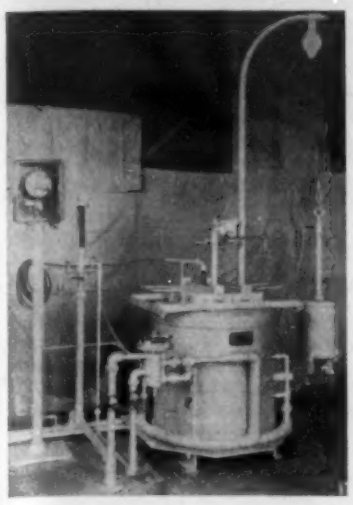
In a discussion on protective linings on sewerage pipes now in use to prevent tuberculation and corrosion with its consequent friction loss it was brought out that bituminous linings have proved the best. Cement linings had given trouble due to becoming loose. The bituminous lining is centrifugally applied at 420° F. Ha (32)

The Principal Operations and Equipment in Enameling. (Die hauptsächlichsten Arbeitsgänge und Einrichtungen beim Emaillieren.) *Sprechsaal für Keramik, Glas, Email,* Vol. 65, Aug. 4, 1932, pages 575-577.

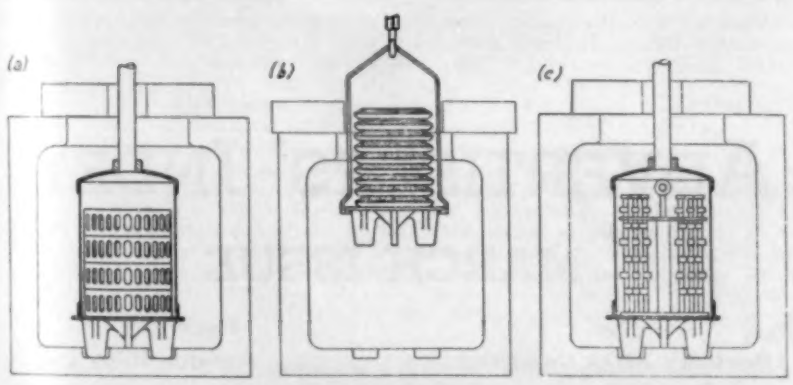
The first of a series of articles on enameling. Discusses the pickling of raw ware to be enameled. GN (32)

The M B V-Method. (Das M B V-Verfahren.) *Apparatebau,* Vol. 44, July 22, 1932, pages 102-103.

The M B V (Modified Bauer-Vogel) method which was developed in 1931 by the Erftwerk, Grevenbroich, Germany is a coating method for protecting Al and Cu- rich Al alloys against the chemical attack of a large number of substances. The parts to be coated are dipped into an aqueous solution of calcinated $Na_2CO_3 + Na_2CrO_4$ at 90°-100° C. After 5- 10 minutes the parts are covered with a light to dark gray coating which resists hot and cold water, alcohol, diluted and concentrated solutions of NaCl but not acids and alkalies. Procedure, costs, properties and use of the new coating method are discussed. There was also developed a special method to be used at lower temperatures, by adding to the above M B V salt 150-160 g. of caustic potash/kg. of the salt. GN (32)



The Technique of Enameling. (Das Emailliertechnik.) *Sprechsaal für Keramik, Glas, Email,* Vol. 65, Mar. 31, 1932, pages 241-242; June 2, 1932, pages 407-408.



Abstract of J. E. Hansen papers in *Sheet Metal Industries.* See *Metals & Alloys,* Vol. 3, June 1932, page MA 191. GN (32)

NEW EQUIPMENT AND MATERIALS

Bell Type Retort Furnace

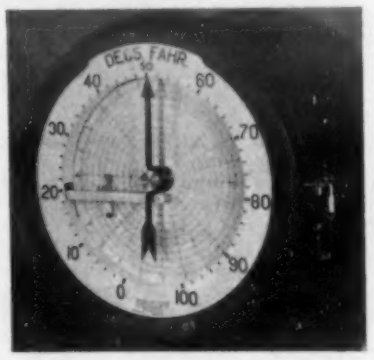
The New Universal Heat Treating Tool, as this bell type retort furnace is termed by its manufacturers, the American Gas Furnace Company, Elizabeth, N. J., is adapted for carburizing, nitriding, or either a carburizing hydrocarbon gas, ammonia for nitriding, or a neutral or inert gas for bright annealing, etc. According to the manufacturer, it can also be used for hardening, normalizing, annealing and tempering, and is "ideal for the jobbing shop where a great variety of work is handled from day to day." For the larger shop it is equally desirable because a battery may be installed and carburizing and other heat treating operations may be carried on simultaneously. Carburizing may be carried to a depth of 1/16" in one furnace and 1/64" only in the adjacent furnace. Other heat treating operations may be performed in still other furnaces. Small sizes are available which may be quickly heated to temperature and various heat treatments may then be performed successively with minimum delay. It is necessary only to have 2 or 3 spare bells with bases available to permit carburizing, then hardening followed by tempering. In annealing, to obtain a full anneal, work may be allowed to remain over night in the furnace after it has been shut down. This also applies to carburizing, should it be desired to obtain maximum diffusion and gradation of case to core. In this case the carburizing gas should be allowed to continue to pass through the retort during the slow cooling period, burning in the furnace and thus retarding the rate of cooling. Where comparatively slow cooling is satisfactory, the bell with its base and work may be removed from the furnace and air cooled or placed in a pit. Quenching direct from furnace temperature can be accomplished either by removing the bell, allowing the work on the base to remain in the furnace for removal of the individual pieces and quenching, or, as for example in the case of ring gears or other comparatively large gears, a special yoke may be used to elevate the base and work slowly so that the individual gears may be withdrawn and quenched in a jig, fixture, or quenching machine, as desired. (See Fig. b.)

The bells are not necessarily cylindrical as in Figs. a and c but may be rectangular or of some other shape better adapted to the particular work. Uniform results are said to be obtained because the retort is entirely enclosed in the furnace. In the case of carburizing, the spent carburizing gears escape from the bottom of the bell and are consumed in the furnace, thus increasing efficiency. Radiation losses are low and fuel economy said to be high. Extra bells are supplied according to the nature of the requirement so that the furnace can be maintained in production all the time. Furnace is provided with automatic temperature control, and with a flow meter for checking the flow of gas through the retort at all times. Two or more flow meters can be supplied where 2 or more gases are to be mixed for passing through the retort as, for example, in applying the Machlet Ni-Carb-Case.

Metals & Alloys, March 1933.

Metal Polish in Powder Form

Products heretofore on the market give unstable suspensions in naphtha or gasoline and are unsuitable for use in making water base polishes, according to the Hull Co., Brooklyn, N. Y., which has brought out a new one consisting of silica and suitable emulsifying and stabilizing agents, and manufactured and sold in dry form. The consumer mixes the powder with water in the proper proportion to give a stable water base metal polish for use. Supply houses buy in bulk, mix with water, put in cans under their own label and sell to consumer trade as liquid metal polish. The product was recently used, in liquid form, in filling a government bid.



Metals & Alloys, March 1933.

Beryllium Copper Alloys

The Riverside Metal Co., Riverside, N. J., has begun the manufacture of beryllium copper alloys. The company is producing beryllium copper in the form of rods, sheets, wire and strip.

Metals & Alloys, March 1933.

Indicating-recording Potentiometer

A new round-chart Micromax Indicating Recorder, announced by Leeds & Northrup Co., Philadelphia, is said to be a "junior instrument, not capable of all that the strip-chart Micromax can do, but it brings the reliability and low-cost maintenance of the motor-driven null recorder to a price class that has never enjoyed these advantages before." These characteristics are said to be especially valuable in pyrometers of about 400 to 900 or 1000°F. range. The new instrument has a boldly-lettered circular scale, and uses a 24-hour 10" circular chart which has straight-line time coördinates, instead of curved ones, on a calibrated portion 3½" wide. The recorder is made as a single-point instrument only, and can be equipped with 2 signal or control contacts. Potentiometers are manually standardized. The mechanism, mounted on a frame hinged to the case, may be swung out if desired. The case is 16½" diameter, and may be mounted either flush or hanging on the face of a wall or panel.

Metals & Alloys, March 1933.

Photographic Plate

Designed especially for photomicrography of metal specimens, a new photographic plate, announced by the Eastman Kodak Co., Rochester, N. Y., is not only particularly suitable for metallography but should appeal, it is said, to photomicrographers who prefer not to use panchromatic plates, such as the Wratten "M" plate, which require handling in the dark. The characteristics of Wratten Metallographic Plates which render them specially useful for metallography are high resolving power; availability of a very high photographic contrast, for such subjects as steels at high magnification; availability of lower contrasts, yielding good negatives where there is high contrast in the image, as with steels at low magnifications, cast irons, etc.; high green sensitivity as well as high sensitivity to blue light, when used either with achromatic objectives and green filters or with apochromats (the speed under green light is unusually high in view of the high contrasts obtainable, the speed under blue light has been achieved without sacrifice of the emulsion's resolving power); absence of sensitivity to red light: the plates can be handled in the normal red light of a Wratten Series 2 Safelight.

Metals & Alloys, March 1933.

New Bearing

Made in sizes up to 32" O.D. from synthetic resin similar to Bakelite and with textile material as the base, a new bearing brought out by Joseph T. Ryerson & Son., Inc., Chicago, is neither fusible nor soluble after treatment: the composition cannot be re-softened by heat, will not absorb water or oil and is resistant to most acids. It is, however, attacked by hot caustic alkalies. "Ryertex," as this new product is called, shows a Brinell reading of about 30-40 and a Scleroscope reading of 70-80, and will outlast babbitt and bronze applications from 4 to 10 times, it is said. The bearings are particularly satisfactory where water is applied as a lubricant. For rolling mills and other special applications, it is said that the greater hardness of the bearing permits the roller to hold his section better as the wear is much slower. In the major steel mills, roll neck and roll table bearings in rod, strip, bar, structural, plate and blooming mills, etc., have successfully passed tests. The difficulty and expense of keeping mill bearings oiled, and the fact that there is plenty of water already available, make this type of bearing suitable for these applications.

Metals & Alloys, March 1933.

MANUFACTURERS' LITERATURE REVIEWS

47 **Phosphor Bronze**—Booklet B-15 of the American Brass Company, Waterbury, Conn., discusses the physical properties and applications of their phosphor bronze. This is furnished in several grades, depending on the use to which it is to be put.

48 **The Alloy Pot**—Vol. 1, No. 1, of this series of folders issued by the New Jersey Zinc Co., New York, N. Y., features a table showing the physical properties of the Zamak alloys. The company plans to discuss new and interesting zinc die castings in each number.

49 **Croda Fluid**—A leaflet describing the three grades of this rust preventive is being distributed by Cox, Aspden & Fletcher, 26 Courtlandt St., New York, N. Y. It is useful for the protection of steel goods or parts in transit and for the preservation of equipment which is temporarily out of service. It is supplied in red or blue color, as well as its natural light brown.

50 **Nitralloy**—The three groups of Nitralloy are described in a leaflet recently issued by The Nitralloy Corporation, 230 Park Ave., New York, N. Y. It also discusses the special alloy steels classified as "Nitrard" which give a core hardness of 500-650 Brinell, and "Nitricastiron," their nitrided cast iron. Lists of applications for the alloys are given.

51 **Gas Burning Equipment**—The North American Manufacturing Co., 2910 East 75th St., Cleveland, Ohio, has prepared a leaflet devoted to their blast burners, butterfly air valves, nozzles, burner tips, etc. Illustrations and prices are shown. Other leaflets by the same company describe their "Duplex" Shut-off Valves, High Pressure Gas Burners, Oil Burning Equipment and Turbo Blowers.

52 **Enduro Stainless Steel**—A most attractive bulletin sent out by the Republic Steel Corp., Massillon, Ohio, discusses their Enduro stainless alloys, giving their analyses, physical properties and data on their proper fabrication. Numerous illustrations show typical methods of installing these alloys.

53 **Herculoy**—A recent bulletin of the Revere Copper & Brass, Inc., New York, N. Y., describes their "Herculoy," a silicon bronze which combines high strength with a high resistance to corrosion. The dimensions, gages and prices of Herculoy in various shapes are given.

54 **Wrought Iron Billets**—The A. M. Byers Co., Pittsburgh, Pa., has prepared a leaflet on their wrought iron billets. These billets are furnished in all desired sizes and a price list for various specifications is included in the bulletin.

55 **Electric Heating Units**—Bulletin GEA-1520A of the General Electric Co., Schenectady, N. Y., describes their line of small heating units and devices such as immersion heaters, strip heaters, metal-melting pots, glue pots, soldering irons, control equipment, etc. Bulletin GEA-1145B discusses their steam turbines for the mechanical drive of pumps, fans, compressors, pulverizers, etc.

56 **Instruments for Spectrographic Analysis**—A 48-page booklet issued by the Bausch & Lomb Optical Co., Rochester, N. Y., is designed for two classes of workers. The first group includes experienced research workers who need only detailed descriptions of the instruments to guide them, and the second includes workers in analysis and research who have little or no detailed knowledge of spectrographic methods. The chapter "Spectrography in the Analytical Laboratory" will be of especial interest and assistance to this latter class.

57 **Q-Seal**—The Quigley Company, Inc., New York, N. Y., has issued their Bulletin No. 207 describing their "Q-Seal," a plastic, expansive joint sealing compound for industrial use. It is said to be high pressure steam-, oil-, acid- and chemical-proof. Their Bulletin No. 305 is devoted to "Mono-Line," a highly stable plastic refractory for monolithic, air- and gas-tight furnace linings, and for quick and durable furnace repairs.

58 **Pyro Radiation Tubes**—Bulletin No. 40 of the Pyrometer Instrument Co., New York, N. Y., gives the specifications for their standard types of radiation tubes, showing two suggested installation methods.

59 **Electric Furnaces**—The Pittsburgh Lectromelt Furnace Corp., Pittsburgh, Pa., is distributing reprints of an article entitled "Essex Slashes Camshaft Costs with Electric Furnace Alloy."

60 **Flexarc Welders**—Two leaflets describing the new 300 and 400 amp. gasoline engine driven Flexarc Welders have recently been announced by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. Both welders may be used with bare or coated electrodes.

61 **High Chromium Cast Iron**—A leaflet sent out by the Electro Metallurgical Co., New York, N. Y., refers to their high chromium cast irons (Cr = 15-30%). These irons are practically free from growth at high temperatures, show little scaling and are resistant to many forms of corrosion.

62 **Metal Melting Furnaces**—The Monarch Engineering & Mfg. Co., 1206 American Bldg., Baltimore, Md., has prepared a leaflet describing and illustrating their furnaces for the melting of brass, bronze, copper, aluminum, etc. They may be either oil or gas fired.

63 **Progress in Oxy-Acetylene Welding**—The feature article in the January issue of Oxy-Acetylene Tips, published by the Linde Air Products Co., New York, N. Y., is a brief but interesting review of oxy-acetylene developments during 1932. Other articles in the same issue are "Welding High Manganese Steel" and "The Foundry Economizes."

64 **Heat Treating Furnaces**—A bulletin recently issued by the Surface Combustion Corporation, Toledo, Ohio, describes and illustrates several of their heat treating furnaces, giving operating data for various types.

65 **Seamless Pipes and Tubes**—Bulletin No. 20 of the National Tube Co., Pittsburgh, Pa., is devoted to their 4-6% chromium seamless pipes and tubes. Tables showing the physical properties of these tubes are included as well as charts which illustrate their high temperature properties.

66 **Pipe for Water Wells**—A folder which has just been published by the Republic Steel Corp., Youngstown, Ohio, explains the numerous advantages of their electric weld pipe which make it useful for well drilling.

67 **Luxit**—A recent folder of the Alpha-Lux Co., New York, N. Y., describes the process to be used in patching furnace linings and for lining gas or oil fired crucible furnaces and ladles.

PROPERTIES OF METALS (1)

The Electrode Potential of Iron. Part I. Measurements in an Atmosphere of Hydrogen. KWANJI MURATA. *Journal Society of Chemical Industry, Japan,* Vol. 35, May, 1932, pages 209B-214B.

Experiments were performed to determine the reversible electrode potential of active Fe in nearly the same way as in the case of nickel (K. Murata, *Bulletin Chemical Society,* Japan, Vol. 3, 1932, pages 57, 253, and 267), but with more precautions. After carrying out a large number of preliminary experiments, it was found that a sintered mass of Fe powder was the best in its reproducibility and that the absolute exclusion of O from the electrode and the electrolyte and also of free acid from the latter are the essential requirements for the reversibility of the potential. The procedure and apparatus are described. The results are given in tables and graphs. As the true standard electrode potential of Fe at 25° C., the value –0.4265 volt is accepted by the reason stated in the experimental part and the free energy of formation of ferrous ion at 25° C. is calculated to be –19,670 calories. MAB (1)

Magnesium. Melting, Pouring, Casting, Utilization. (Le magnesium. Fusion-coulee-fonderie-utilisation.) R. DE FLEURY. *Revue de Metallurgie,* Vol. 29, July, 1932, pages 341-346.

Mg must be protected with a layer of flux in melting. Excess chloride flux contaminates the metal with entrapped salts, thus affecting its corrosion resistance. 2 fluxes are recommended. The metal is melted with the first flux (60 $MgCl_2$, 40 NaCl or KCl). At about 730° C. the flux rises to the top. This temperature is maintained for about 10 min. The second flux, composed of fluorides, is then added in an amount equal to 20-30% of the first flux. A solid crust on the surface gives better protection. This is obtained by changing the composition of the fluoride flux. 2 formulas are recommended: 85 MgF_2, 5 NH_4HF_2, 3 NH_4Cl, 7 BO_3 (fused), 15 BaF_2 and 5 NH_4HF_2, 7 BO_3 (fused), 3 NH_4Cl, 70 MgF_2. Violent reaction with the moisture of the molds is prevented in casting Mg by adding to the sand substances volatilizing at the casting temperature among which are: tars, naphthalene, sulphur, volatile organic salts, etc. These form a species of neutral layer around the metal. Boric anhydride and ammonium borate stand between these 2 classes. As the remelting lowers the qualities of Mg a formula is proposed for estimation of these qualities in terms of the number of the remelts. Mg flowing past the mold wall overheats it and destroys the protective action of additions. The amount of local overheating must be reduced by increasing the number and reducing the size of the gates. JDG (1)

First Report of the Committee on Atomic Weights of the International Union of Chemistry. G. P. BAXTER, Chairman. *Journal American Chemical Society,* Vol. 53, May 1931, pages 1627-1639.

The report includes the metals Ca, V, Cr, As, Ta, Re, Tl and Pb (RaG). A summary of the work of Aston (mass spectrograph) on the metals Cr, Zn, Mo, Sn and Hg with the isotopic weights and percentages, the packing fractions and the atomic weights are given. MEH (1)

The Suitability of Tantalum as a Material for Laboratory Apparatus. (Ueber die Eignung von Tantalmetall als Werkstoff für Laboratoriumsgeräte.) B. FETKENHEUER & E. CREMER. *Siemens-Zeitschrift,* Vol. 12, May 1932, pages 168-171.

Very comprehensive tests were made with pure, gas-free Ta with respect to resistance to chemicals. Ta melts at 3027° C. and is, in the pure state, very ductile and can be rolled to sheets of 0.05 mm. It absorbs gases readily when it is red or white hot; at 600° C. it can absorb up to 740 times its own volume. On account of its resistance to acids it can often replace Pt and is sometimes even superior to it. It was further determined under which conditions Ta can be used instead of Pt as cathode material for electrolysis in the deposition of Cu, Zn, Ni, Co, Ag, Au, and Cd. It cannot be used for the deposition of Sn. The results of 36 tests with chemicals are tabulated. Ha (1)

Magnesium—Industry's Lightest Structural Metal. JOHN A. GANN. *S. A. E. Transactions,* Vol. 26, 1931, pages 620-634, 641.

The Diffusion Speed of Copper in Gold. (Die Diffusionsgeschwindigkeit von Kupfer in Gold.) W. JOST. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 16, Mar. 1932, pages 123-128.

Annealed Cu wires of 0.5 mm. diameter were electroplated with a Au-coating 4-12 x 10^{-4} cm. thick. Samples were exposed to temperatures between 300° and 616° C. for 10-2850 min. After being heat-treated the samples were investigated by X-rays and the diffusion constants were computed. The calculations are based on the changes of the space lattice constants. The data obtained which are presented graphically, are in fair agreement with the results of Eisenhut & Kaupp (*Zeitschrift für Elektrochemie,* Vol. 37, 1931, page 460) but are not in accordance with Tannaka & Matano (Mem. Coll. Sc. Kyoto Imp. Univ. Vol. 14, 1931, page 59) who determined the diffusion constants by conductivity measurements. EF (1)

1 **The Magnetic Properties of Iron and its most Important Alloys. (Die magnetischen Eigenschaften des Eisens und seiner wichtigsten Legierungen.)** O. VON AUWERS. *Die Naturwissenschaften,* Vol. 20, Apr. 8, 1932, pages 257-264.

— The maximum permeability of "Fe" has been increased 30. times during the last 30 years while the hysteresis loss is only 6% of the value established 40 years ago. The present trend is (A) a scientific one, based on Heusler's discovery of ferro-magnetism in alloys composed of non-magnetic elements and (B) a commercial one, going back to Warburg's interpretation of the hysteresis loop on one hand and to the
2 discovery of the Si-bearing dynamo steel by Barret, Brown and Hadfield on the other hand. The magnetization curves of pure single crystals of Fe along different crystallographic axes is discussed, showing anisotropic behavior, absence of hysteresis losses and a high degree of permeability. Apart
— from the large desirable permeability, the constancy of permeability which is independent of the field density, is of commercial significance. The recent progress along these lines is traced and the results presented in diagrams. Further illustrations compile data from B-H, μ-H, μ_0-frequency measurements on Si-bearing dynamo steel, Permalloy A, B,
3 C, electrolytic Fe, Hypernik, and Perminvar of various analyses. In this historical review, emphasis is placed on the contributions of Elmen, Masumoto and Kuehlewein. The writer derives that the latest technical alloys are leading back to the crystal-physics of scientific ferro-magnetism which is more or less a problem of internal stresses and
— crystal structure. EF (1)

Observations on the Pressure of Fluidity of Annealed Metals. HUGH O'NEILL & HUBERT GREENWOOD. *Journal Institute of Metals,* Vol. 48, 1932, pages 47-68.
4 Includes discussion. See *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 233. (1)

Diffraction of Low-Speed Electrons by Single Crystals of Copper and Silver. H. E. FARNSWORTH. *Physical Review,* Vol. 40, May 1932, pages 684-712.

Single crystals of Cu and Ag were prepared by the "solidification from the melt method." The methods used are de-
— scribed briefly. Previous results on diffraction beams for normal incidence on the (100) faces of Cu and Ag are checked and extended. Diffraction beams due to a surface lattice on the (110) faces of Cu and Ag formerly reported
5 have since been found to decrease in intensity after prolonged heat treatment of the Cu crystal at temperatures near its melting point. Experimental methods of distinguishing between effects due to surface action and those due to a space lattice are discussed. WAT (1)

— **Observations on the Rare Earths. XXXVII. Electrolytic Preparation of Rare Earth Amalgams. 1. Preparation of Amalgams of Lanthanum and Neodymium.** L. F. AUDRIETH, E. E. JUKKOLA & R. E. MEINTS, with B. S. HOPKINS. *Journal American Chemical Society,* Vol. 53, May 1931, pages 1805-1809.
Presented before the Division of Physical and Inorganic Chemistry at the Indianapolis meeting of the American
6 Chemical Society, Apr. 1931. Amalgams of neodymium and lanthanum may be prepared by electrolysis of aqueous and alcoholic solutions of various salts using a mercury cathode. These amalgams are extremely reactive and undergo ready decomposition. The free metals may be obtained from them
— by heating the amalgams in vacuo. MEH (1)

— **Thermal Expansion of Lead.** PETER HIDNERT & W. T. SWEENEY. *Physical Review,* Vol. 35, Feb. 1930, page 296.
Data on the linear thermal expansion of a sample of cast Pb and various Pb-Sb alloys between 20° and 60° C. were published in 1924 by Vinal. Since then additional determina-
7 tions were made on 3 samples of cast Pb over various temperature ranges between 20° and 300° C. The results show that the differences obtained in the coefficients of expansion were evidently due to variations in the methods of casting. WAT (1)

— **A New Commercial Metal—Indium.** ELLIS K. BALDWIN. *Brass World,* Vol. 28, May 1932, pages 98-99.
Broad possibilities are predicted for indium in jewelry, dental work, the electric field, automobile hardware, radio, and television. WHB (1)

8 **The Thermochemistry of Thallium. (Zur Thermochemie des Thalliums.)** W. A. ROTH & A. MEICHSNER. *Zeitschrift für Elektrochemie,* Vol. 38, Feb. 1932, pages 87-93.
The heat changes associated with a series of reactions were measured calorimetrically. The e.m.f. and its temperature coefficient were determined for the cell: Zn | $ZnSO_4 \cdot 3200\ H_2O$ | $Tl_2SO_4 \cdot 3200\ H_2O$ | Tl. The solubility of TlCl in dilute
— aqueous HCl at 20° C. was determined. From these auxiliary data, the heats of the following reactions in $kg.cal._{15}$ for 20° C. and constant pressure, weights not reduced to vacuum, were computed. Ha (1)

9 **Experiments on the Polarization of Electrons. (Versuche zum Nachweis einer Polarisation der Elektronen.)** E. RUPP. *Physikalische Zeitschrift,* Vol. 33, Feb. 15, 1932, pages 158-164.
Paper before the Deutsche Physikalische Gesellschaft, Bad Elster, Sept. 1931. Reports on experiments on the polarization of electrons (1) double reflection under a glancing angle of incidence and (2) under 90° scattering angle and
— subsequent passing of a thin foil. The first set of experiments yielded an unequal reflection of 6-8% on W, 7-11% on Au and 12-14% on Th in case of electrons of 80 kv. On Be, Al and Ni no polarization could be observed within the limit of error (3-5%). Hydrogen canal rays of 20 kv. dis-
10 charge voltage do not exhibit a polarization. The data gained with the testing conditions mentioned under (2) are graphically presented and show the correlation of the polarization to the ray velocity and nature of the reflecting metal. By the agency of external magnetic fields, it is shown
— that the polarization effect is closely related to the magnetic moment of the electron. EF (1)

Properties of Copper Deoxidized with Calcium. LYALL ZICKRICK. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 11 pages.

Small melts of Cu were deoxidized with Ca, Si, CaB_6 or combinations of these materials. All but 0.002% O was removed by 0.0375% Ca. Small ingots cast from the deoxidized Cu had deep pipes characteristic of such material. Particles of what appeared to be a Ca-rich compound were observed in the microstructure of the deoxidized Cu. Wires were drawn and their properties determined in the cold-drawn condition and after annealing at various temperatures. Residual Ca and Si increased the softening temperature, and decreased electric resistance. The tensile strength and elongation were not greatly affected by deoxidation. 6 references. JLG (1)

Radiation Properties of Oxidized Palladium. (Strahlungseigenschaften von oxydiertem Palladium.) W. ZOBEL. *Annalen der Physik,* Series 5, Vol. 9, No. 5, 1931, pages 519-536.

In the range of 300° to 600° C. the temperature radiation of oxidized Pd was measured as a function of the surrounding pressure. At 0.01 mm.Hg a steep maximum was found, after which the radiation drops below the initial value. The pre-treatment of the metal has a considerable influence on the radiation. Ha (1)

Copper Embrittlement, II. L. L. WYMAN. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 11 pages.

Cu was deoxidized by 1 or more of the following substances: Ca, CaB_6 or Si. The samples were rolled into sheet and heated alternately in oxidizing and reducing atmospheres. Deterioration due to such treatment was detected by bend tests and microscopic examination. None of the Ca-deoxidized Cu was affected by the usual H embrittlement. The double deoxidized samples had the highest resistance to alternate heatings in oxidizing and reducing atmospheres. 4 references. JLG (1)

The Melting Point of Iridium. (Der Schmelzpunkt von Iridium.) H. VON WARTENBERG, H. WERTH & H. J. REUSCH. *Zeitschrift für Elektrochemie,* Vol. 28, Feb. 1932, page 50.

From 50 observations on specially prepared pure Ir, the melting point was found to be 2435 ± 15° C. (calculated with $c_2 = 14{,}320$). A few percent of Os or Ru increase the melting point several 100°. 5 references. Ha (1)

Ferromagnetism and Electric Properties. V. The Thermomagnetic Effect in the Longitudinal Magnetic Field as Observed on Nickel and Iron. (Ferromagnetismus und elektrische Eigenschaften. V. Der thermomagnetische Effekt im longitudinalen Magnetfeld beobachtet an Nickel und Eisen.) HEINZ BROILI. *Annalen der Physik,* Series 5, Vol. 14, Aug. 1932, pages 259-272.

If a temperature gradient exists from one end of a wire to the other and at the same time a longitudinal magnetic field is applied parallel to the temperature gradient, an e.m.f. exists at the ends of the wire; the polarity depends on the direction of the temperature gradient and is independent of the direction of the magnetic field. The relations between e.m.f. and magnetization and temperature were investigated and the tests are described. 11 references. Ha (1)

The Magnetization of Iron Immediately above the Curie Point. (L'Aimantation du Fer immediatement au dessus du Point de Curie.) L. NEEL. *Revue Generale de l'Electricite,* Vol. 31, May 21, 1931, pages 699-700.

The magnetic susceptibility of Fe changes very rapidly with the temperature within about 10° just above the Curie point; even for temperature differences of only 0.03° C. extremely large magnetic variations take place. See also *Metals & Alloys,* Vol. 3, June 1932, page MA 158. Ha (1)

Gmelins Handbook of Inorganic Chemistry. Iron. (Gmelins Handbuch der anorganischen Chemie, Eisen.) Part B, Section 5. Verlag Chemie, Berlin, 1932. Paper, 7 x 10 inches, 293 pages. Price 53.50 RM.

This is the fifth and last section of Part B of the volume on iron. The survey on iron compounds is completed in discussing the compounds of Fe with Li, Na, K, NH_3, Rb, Be, Mg, Ca, Sr, Ba, Zn, Cd, Hg, Al, Ga, In, Tl, rare earths, Zr, Th, Sn, Pb, V, Nb, Cr, Mo, W, U, Mn, Ni and Co. It does not discuss alloys. For reviews of earlier sections of this work see *Metals & Alloys,* Vol. 1, Dec. 1930, page 918; Vol. 2, Oct. 1931, page 207; Vol. 3, May 1932, page MA 116.

Technical Materials, Their Properties, Defects and Testing. (Die technischen Werkstoffe, Ihre Eigenschaften, Fehler und Prüfung.) OTTO SCHWARZ. Johann Ambrosius Barth Verlag, Leipzig, 1932. Paper, 6¾ x 9¾ inches, 222 pages. Price 24.50 RM.

In a clear and concise manner the author presents the properties of the important materials of construction. While too brief to do complete justice to the title, the space devoted to various subjects conforms well to their relative importance.

Mechanical properties are defined and described in a brief but adequate manner. Then, even more briefly the concepts of physical metallurgy are presented.

The body of the book deals systematically with the properties of specific materials. Non-metallic materials are briefly mentioned. The book closes with a description of machines and instruments for testing materials.

The treatment is quite up-to-date. Nothing of only historical interest is described. While some of the data are probably new the book contains little which has not been previously known. It should prove to be a good reference book. H. W. Russell (1)-B-

Metallurgical Properties of Metals and Their Effect upon Welding Operations. JOS. F. OSTERLE. *Welding Engineer,* Vol. 17, July 1932, pages 28-29, 39.

A general survey of the properties of metals as far as they are of importance to welding, their chemical affinities to form compounds and alloys, their structure, effects of heat and work on crystal size and the influence of impurities on welding characteristics. Ha (1)

Principal Factors in the Castability of Pure Metals. (Facteurs Principaux de la Coulabilité des Metaux Purs.) A. PORTEVIN & P. BASTIEN. *L'Usine,* Vol. 41, Mar. 18, 1932, page 29. See *Metals & Alloys,* Vol. 3, Sept. 1932, page MA 261. Ha (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

The Thermal Conductivity of Some Non-Ferrous Alloys. D. HANSON & C. E. ROGERS. *Engineering,* Vol. 133, Mar. 18, 1932, pages 354-355.

Preparation of a Special Brass. (Herstellung eines Sondermessings.) R. BERGER. *Zeitschrift für die gesamte Giessereipraxis, Das Metall,* Vol. 52, Aug. 30, 1931, pages 85-86.

The preparation of a corrosion resistant special brass of great hardness is fully described, the following data being included: Analysis = 58% Cu, 35% Zn, 2% Al, 2% Ni, 2% Mn, 1% Fe; tensile strength = 50-60 kg./mm.²; elongation = 15-25%; Brinell hardness = 110-130. The utilization of highly pure metals is stressed in order to secure values given above. Cu of at least 99.6% and Zn of 99.9% are used as virgin metals, while Al is introduced as an 80/20 Cu-Al alloy. Fe, Mn and Ni are added as a Cu alloy of about 68% Cu. Al raises the yield point (1% = + 10 kg./mm.² while elongation drops 8% per 1% Al). Fe induces a fine grain and slightly increases both elongation and tensile strength up to 1% Fe. Mn improves the corrosion resistance and otherwise acts the same way as Al and Fe. Ni exerts the same effect as Mn. The preparation of the primary alloys and the casting of the final alloy is fully outlined. The use of scrap and the most suitable form and material for the mold are discussed. EF (2)

The Thermal Conductivity of Some Non-Ferrous Alloys. D. HANSON. *Journal Institute of Metals,* Vol. 48, 1932, pages 37-45. Includes discussion. See *Metals & Alloys,* Vol. 3, Oct. 1932, page MA 289. (2)

Study of the Composition of a Roll Bearing. (Etude de la composition d'un coussinet de laminoir.) M. G. ANTOINE. *La Fonderie Belge,* Vol. 2, Feb. 1932, pages 31-34.

The original melt was of Cu-Sn alloy with Zn, Pb, Ni and P additions. The pouring temperatures were difficult to check due to the fumes and vapors which made the optical pyrometer useless. Factors studied are: (1) Length of life in service. (2) Wear. (3) Mechanical properties. Results are expressed in 4 diagrams and 2 tables. Structure is given in 4 micrographs. Summary of results: (1) P has a considerable effect upon the length of life which increases with the P content. (2) Increasing the Sn content to 12-13% is not advisable because brittleness is such that the bearing cannot resist the shocks of the roll. (3) A high Ni content increases hardness and causes rapid breakage. (However bearings with 3-4% Ni are used with coating of white metals. Ni is then useful for improving the crushing strength). (4) Pouring temperature has an effect upon the properties of the metal; a high pouring temperature would give better bearings. FR (2)

Ordinary and Special Bronzes: Zinc Bronzes. (Les Bronzes Ordinaires et les Bronzes Spéciaux: Les Bronzes au Zinc.) LEON GUILLET. *Cuivre et Laiton,* Vol. 5, July 15, 1932, pages 305-306.

The general properties, structure and compositions used for practical purposes are briefly discussed. Ha (2)

Effect of Crystal Size on Physical Properties of Tin-base Babbits. ERNEST B. DRAKE. *Metals & Alloys,* Vol. 3, Mar. 1932, pages 77-81.

The author presents the results of casting an 85% Sn, 7.5% Cu, 7.5% Sb babbitt metal from temperatures from 750° to 1000° F. with mold temperatures from room temperature to 450° F. The study consisted of macro and micro examination of the structure, hardness tests and compressive strength tests. The results show that the crystal size of cast babbitt may be controlled by means of casting and mold temperatures, that the hardness as measured is not related to crystal size and that the compressive strength decreases somewhat with increased crystal size. WLC (2)

New Antifriction Alloys with High Content of Copper and a Lead Base. (Nouveaux Alliages Antifrictions à haute Teneur en Cuivre et à Base de Plomb.) A. RICARD & H. ACKERMANN. *Cuivre et Laiton,* Vol. 5, July 15, 1932, pages 295-304.

The study of antifriction alloys has shown that they must possess a heterogeneous structure and a basis of solid solutions or eutectics or a mixture of the two, in which hard particles are embedded. This is necessary in order to permit the rubbing surface to follow the deformations of the rotating piece while the hard parts resist the friction and are worn by it. While formerly bearing metals had mostly a base of Sn, recently equal and even better antifriction metals have been made with a base of Pb and large additions of Cu. A list of the principal alloys in general use is given in the following table:

No.	Sn	Sb	Cu	Pb	Use
..	95.5	1.2	1.5	1.43	Aviation
..	93	3.5	3.5	...	
1	83	11	6	...	Charpy alloys
2	76.5	11	5	7.5	Machinery
3	71.1	9.5	4.35	14.52	Street Cars
4	60	13	5	22	Locomotives
5	50	14	5	31	Railroad Cars
6	40	15	5	41	High Speed Steam Engines
7	38	10	3	19	Freight Train Locomotives
8	16	16	3	65	
9	5.5	16.5	2	76	
10	0	17	1.5	81.5	Freight Cars

The alloys with Pb-base and high Cu-content behave just as well in cold as in hot state and with or without perfect lubrication. This is mainly ascribed to the high heat-expansion coefficient of the Pb which has the effect that the homogeneous mixtures of Cu or its alloys with Pb become the seat of a displacement of the Pb for each temperature difference and the more uniform this displacement, the more intimate the mixture. At the least temperature increase the direct contact or friction between the surfaces is therefore avoided as the Pb acts, so to speak, as lubricant. A number of tests are cited describing the experiences and behavior of bearings without any lubrication. Speeds up to 30 m./sec. and pressures up to 100 kg./cm.² have been applied without any appreciable wear; the surface showed a fine polish. Ha (2)

Ordinary Bronzes and Special Bronzes. (Les Bronzes Ordinaires et les Bronzes Spéciaux.) Leon Guillet. *Cuivre et Laiton,* Vol. 5, Mar. 30, 1931, pages 127-128.

The equilibrium diagram of binary Cu-Sn alloys is explained and compared with that of Cu-Zn. From 0 to 12% Sn the solid solution α exists, from 12 to 28% another constituent, δ, appears, Cu_4Sn. Between 28 and 32% are bronzes of pure δ formation. For industrial purposes, however, 2 groups of Cu-Sn alloys are used: bronzes up to 10% Sn, solid solution α, and bronzes 10 to 25%, built up of $\alpha + \delta$. The δ is hard and the hardness increases with the Sn content. The α-bronzes are used for their ductility and mechanical qualities, the $\alpha + \delta$ bronzes for pieces which have to stand friction, for bells and art pieces. The mechanical properties are described for each kind of bronze. The bronzes with 8 to 10% Sn have not yet been fully investigated. Ha (2) 1

Recent Developments in Zinc Die Castings. W. N. Peirce. *Paper* presented at 14th Annual Meeting of *American Zinc Institute,* St. Louis, Apr. 1932, 5 pages; *American Metal Market,* Vol. 39, Apr. 19, 1932, page 10.

The progress of Zn die castings made in recent years is reviewed. Especially have alloys low in Pb content been developed which are of great stability so that they can safely be used for gasoline motor parts, electric motor parts, telephone equipment with very narrow dimensional tolerances which formerly has been impossible. Impurities are almost excluded. The soundness of castings has been greatly improved. The porosity is the smaller the lower the temperature and the higher the pressure at casting. This produces also better material for electroplating. The possible extension of the fields for the application of Zn die castings and further developments are discussed. DTR+Ha (2) 2

Some Effects of Internal Stress on Properties of Drawn Brass Tubes. D. K. Crampton. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 20 pages.

Tubes 0.75" in diameter were drawn from 1 lot of 70-30 brass. The final drawing operation varied with respect to reduction in diameter and reduction in wall thickness; the same die was used in the final draw for all tubes. The following tests were made: (1) tensile in which strength, elongation, apparent elastic limit and modulus of elasticity were determined, (2) Rockwell hardness, (3) time required to crack in $HgNO_3$ solution, (4) stress distribution by modified Fox method, (5) X-ray studies of orientation. Tubes were tested as drawn and after having received a relief anneal at 250° C. for 2 hr. Young's law of proportionality did not hold strictly as the modulus of elasticity was a maximum at zero load and decreased continually as the load increased. Relief annealing did not decrease strength, but it increased surface hardness when the stress released was tension. The time-$HgNO_3$ test gave a good indication of internal stress resulting from drawing or sinking. The method of determining internal stress did not yield precise values, but it did give some indication of the relative stresses resulting from various drawing schedules. Polycrystalline tubes showed stresses 29 to 55% greater than identically treated single-crystal tubes. When tubes are split the hardness of those surfaces that were under tension increases and that of those that were under compression decreases. In sunk tubes the orientation was such that a [112] direction was parallel to the tube axis, a [111] direction radial, and a [110] direction tangential. In drawn tubes a [111] direction was parallel to the tube axis, a [110] direction radial, and a [112] direction tangential. 12 references. JLG (2) 3

Monel Metal. N. C. Marples. *Nickel Bulletin,* Vol. 5, May 1932, pages 97-104.

The nature, mechanical properties of various qualities, the influence of cold-working and some applications of Monel metal are described and illustrated; its corrosion-resistance compares very favorably with Mn bronze; it is used for the filtering of liquids, pickling plant equipment, handling of beverages and foods, etc. Manufacturing methods and treatment are briefly described. It can be Ag soldered with a solder containing Ag 40%, Cu 40%, Zn 20%. Ha (2) 4

Alloys of Aluminum. George Mortimer. *Metal Industry,* London, Vol. 40, Jan. 15, 1932, pages 69-74.

Practical applications of the results of research on causes of cavities are discussed. PRK (2) 5

Cadmium Bronze Trolley Wire Shows Desirable Qualities. *Transit Journal,* Vol. 76, Oct. 1932, pages 405-407.

Cd bronzes with higher annealing temperatures than Cu and higher conductivities than Sn bronzes are suitable material for trolley wire. Short circuit tests indicate that this material resists overloading better than hard-drawn Cu or Sn bronzes while resistance to mechanical wear is approximately the same. CBJ (2) 6

Directional Properties in Cold-rolled and Annealed Commercial Bronze. Arthur Phillips & Carl H. Samans. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 491, Oct. 1932, 12 pages.

Brass containing 90.08% Cu, 9.88% Zn, 0.012% Pb and 0.030% Fe was rolled to 0.032" sheet. 2 lots as finished were cold rolled to a 37% reduction, 2 others to a 56% reduction, and 1 other to a 75% reduction. One reduced 37% was given light reductions and light anneals, while the other was given light reductions and high-temperature anneals. Those rolled to a 56% reduction were given moderate reductions, while 1 was annealed at low and the other at high temperature. Tensile tests were made on specimens whose axis made angles of 0, 22.5, 45, 67.5 and 90° with the direction of rolling. Tests were also made on annealed sheets. The most pronounced directional properties were observed in the brass given the greatest reductions followed by high-temperature anneals. The tensile tests appeared to indicate whether or not the brass will form ears on drawing. In slightly and moderately worked brass, the lower the temperature of intermediate and next to the last anneals, the more marked are the directional differences as shown by tensile and cupping tests. Cu tends to form ears at 90° to the direction of rolling and 90-10 brass at 45°. The directional properties of Cu are decidedly different from those of 90-10 brass. 4 references. JLG (2) 7

Aluminum-Chromium Alloys. (Leghe alluminio-chromo.) G. Gallo & G. Fragapane. *L'Aerotecnica,* Vol. 11, Dec. 1931, pages 1539-1554.

The influence of the Cr content on the corrosion resistance of Al alloys is determined. With Al-Cr alloys the percentage of Cr was varied from 0 to 6. A Cr content below 2% proved to be sufficient for noticeably altering the hardness and the resistance to corrosion. Cr, when added to duralumin, offers no improvement in the corrosion resisting properties. For testing the corrosion an apparatus developed by Tödt was used. GG (2) 1

Brass as a Material in Precision Machines. (Messing als Werkstoff in der Feinmechanik.) K. Grotewold. *Feinmechanik und Präzision,* Vol. 40, June 1, 1932, pages 93-101.

The equilibrium diagram of Cu-Zn is explained, in particular that part with more than 52% Cu is discussed. This is of importance for the precision machine industries which use brasses of this range extensively. Brasses with more than 61% Cu consist, at normal temperature, of pure α-solid solutions, alloys of 61-54% Cu of α- and β-solid solutions and alloys of less than 54.3% of pure β-solid solutions. The structures of these 3 brasses are illustrated by micrographs. The mechanical properties of German standardized pressed and rolled brass are: tensile strength between 35 and 60 kg./mm.² according to whether they are soft, medium-hard or hard, elongation from 5-30%, and the Brinell hardness 75-145, so that a suitable material exists for almost any requirement. The heat or cold treatment is discussed; the stress cracks sometimes occurring in cold-worked metal can usually be eliminated by a heat treatment of 250° to 300° C. without impairing the hardness of the material. In order to find out whether such stresses are in the material that a crack could be expected at the further working of the piece the latter is placed in a solution of mercurous nitrate to which a few drops of HNO_3 are added for about 15 min. The immersed piece is covered with a thin film of mercury which penetrates into the grain boundaries. If stresses exist the piece will tear open after a few minutes; with weak stresses this happens after about 15 min. Articles which are subject to permanent vibrations should be made of annealed wires; hard brass often shows stresses developed by vibrations. Ha (2) 2

Studies on the Improvement of Alloys of the Gold-Platinum System by Small Additions of a Third Component (Studien über die Vergütung der Legierungen des Systems Gold-Platin durch geringe Zusätze dritter Komponenten). Wilhelm Goedecke. Festschrift zum Fünfzigjährigen Bestehen der Platinschmelze (1881-1931). G. Siebert, G.M.B.H., Publisher, G. M. Alberti's Hofbuchhandlung, Hanau. Pages 100-107.

The author first reviews the Au-Pt system and the application of heat treatment to improving the properties of alloys containing 20% or more of Pt. It had been shown that 30% Au, 70% Pt alloy could be hardened to about 400 Brinell. The experimental work covers the effects of heat treatments of Pt-Au-Fe alloys containing up to 2% Fe on the hardness and electrical resistance. The alloys were quenched in water from 800-1000° C. and then reheated at 500 to 550° C. for different lengths of time. Hardness was measured with a 5 mm. ball and 250 kg. load. The hardness of the quenched alloys increased very slightly as the Fe increased to 2%. In a 10% Pt alloy the hardness of reheated alloys increased rapidly as the Fe increased to 0.1-0.2% (over 100%) with little change for larger additions. The time required to produce the maximum hardness decreased from 4 hours for 0.1% to about 10 min. for 1% Fe. Raising the reheating temperature shortens the time required to produce maximum hardening, but causes a more rapid loss in hardness on further heating. A maximum in the hardness of alloys containing 0.2% Fe was noted with 6% Pt. A break in the electrical resistance of a 10% Pt, 0.2% Fe alloy occurred at about 500° C. The experimental part is followed by some theoretical discussion of the mechanism of the hardening of Au-Pt-Fe by reheating after quenching. OEH (2) 3

Lanthanum and Its Alloys. (Le Lantane et ses Alliages.) G. Canneri. *L'Usine,* Vol. 41, Apr. 22, 1932, page 27.

Alloys of La-Mg and La-Cu are briefly described. The addition of La seems to increase corrosion. See also "The Alloys of Lanthanum," *Metals & Alloys,* Vol. 2, Dec. 1931, page 298. Ha (2) 4

Acid Resistant Bronzes. (Säurebeständige Bronzen.) W. Claus & H. Fincke. Wilhelm Knapp, Halle (Saale), 1932. Paper, 6¼ x 9¼ inches, 136 pages. Price 13.80 RM.

Cu, with 0.08% Pb, 0.10% Ni, 0.03% Ag, 0.01% As and bronzes with 3½, 6, 10, 14, 20 and 32% Sn were studied, as cast, and annealed, in NH_4OH, HCl, H_2SO_4, H_3PO_4, sea water, Na_2SO_4, $NaHSO_4$, Na_2CO_3, $CaOCl_2$ and KOH solutions, the specimens being immersed in the solution at room-temperature and the closed container shaken. The results therefore are for relatively unaerated conditions. Corrosion was evaluated by weight loss, no study being made of change in physical properties. Some of the tests were carried on for 10 to 30 days. The results are plotted in 76 curves. Some cast Cu-Zn-Sn and Cu-Sn-Pb, Cu-Sn-Zn-Pb and Cu-Sn-Sb and Monel Metal were tested in similar solutions.

All the complex bronzes showed about the same degree of corrosion-resistance in each solution, irrespective of composition. Monel was slightly superior in NH_4OH, HCl and KOH. The results on the straight-Sn bronzes in the various solutions were about what would have been expected from previous work.

A bibliography of 724 references covering various other Cu base alloys besides bronze and other properties besides corrosion-resistance is appended. There is a name index to the bibliography. There is a table of contents, but no detailed index to the experimental part. H. W. Gillett (2)-B- 7 8 9 10

Some Useful Remarks on the Use of Copper Alloys. (Apercu Utilitaire sur l'Emploi d'Alliages Cuivreux). A. RICARD. *Cuivre et Laiton,* Vol. 5, Apr. 30, 1932, pages 173-175.

The equilibrium diagram of Cu-Sn and the three distinguished quality ranges of bronzes up to 8% Sn from 8 to 14% Sn and above 14%, are briefly explained and the fields of application for each group stated. Ha (2)

The Thermo-dynamic Activities in Binary Alloys. (Beiträge zur Kenntnis der thermodynamischen Aktivitäten in binären Legierungen.) C. WAGNER & G. ENGELHARDT. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 159, Apr. 1932, pages 241-267.

The e.m.f. of galvanic cells built up by liquid alloys and molten salts are measured and the thermo-dynamic activities of the less noble component are determined with reference to the following systems: Pb-Bi, Sn-Bi, Tl-Bi, Mg-Pb. The data gained on the last system are uncertain due to the remarkable reactivity of Mg. The investigation of galvanic cells with alloys in the liquid state at elevated temperatures should be restricted to the nobler metals. The distribution coefficients and heats of mixture derived from activity measurements are compared with data experimentally determined. The applicability of the von der Waals equation of state with reference to binary alloys is discussed. The calculations of R. Lorenz and co-workers on the equilibria alloy-salt phase and on the equation state constants of the metallic phase derived therefrom are compared with the heat of mixtures of the alloys. Furthermore measurements are made on the e.m.f. of cells composed of solid alloys Ag-Au and Cu-Au, and of molten electrolytes for the temperature range of 666-1019° C. and 662-878° C. respectively. The experimental data can approximately be considered as equilibria potentials. EF (2)

The Hall Effect and Other Physical Properties of the Copper-Cadmium Series of Alloys. WALLACE RICHARDS & E. J. EVANS. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Ser. 7, Vol. 13, Feb. 1932, pages 201-225.

Theoretical and mathematical study for the determination of the electrical resistivities, temperature coefficients of resistance, thermoelectric powers, Hall coefficients and specific heats and densities of this series. Tests were made on annealed specimens. RHP (2)

Higher Physical Limits of Monel Metal Forgings. *Inco,* Vol. 11, No. 2, 1932, page 21.

Yield points of over 70,000 lb./in.² with an ultimate tensile strength of more than 90,000 lb./in.² can now be obtained on forged bars from 3" to 6" in diameter with elongations higher than 25%. Ha (2)

Aluminium—Its Production, Properties and Applications. *Gas Journal,* Vol. 198, June 22, 1932, pages 826-827.

Beryllium and Its Alloys. (Über Beryllium und seine Legierungen.) *Das Metall,* Supplement to *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 15, 1932, pages 204-206.

Survey on the properties and application of Be alloys, with special reference to Be bronzes. Be bronzes are superior to other bronzes due to better fatigue properties, higher resistance against corrosion, improved electric conductivity and heat conductivity and higher resistance to wear. Shaping of Be bronzes by drawing, rolling, pressing, stamping etc. offers no difficulties. GN (2)

Special Alloys. (Spezial-Legierungen.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 21, 1932, page 334.

Composition, properties and uses of the following alloys are considered: Bobierre metal, Bolley metal, Bourbon metal, Bolster silver, Brazilian silver, Bourbouze solder metal, Bristol brass and Brix metal. The latter a corrosion-resistant alloy contains 15-20% Cr, 60-75% Ni, 5% Cu, 4% Si, 1-4% W, 2% Al and 3% Mn-Ti. GN (2)

Properties and Some Applications of Tungum Alloy. *Metallurgia,* Vol. 6, July 1932, pages 99-100.

Tungum is a corrosion-resistant Cu-base alloy that can be cast, forged, rolled, or extruded. Tables showing its resistance to various corroding media are given, but its approximate composition is not stated. JLG (2)

"Hydronalium," Light Metal of the German Dye Trust. ("Hydronalium" Leichtmetall der I.G. Farbenindustrie A.G.) *Zeitschrift für Flugwesen und Motorluftschiffahrt,* Vol. 23, Aug. 12, 1932, page 474.

The alloy corresponds to the alloy MG 7 manufactured in England by James Booth & Co., Ltd. The new alloy is lighter than duralumin and needs no improvement by aging. Parts to be joined are best riveted with the alloy MG 5 or "Hydronalium." Rivets made of other Al alloys are to be avoided. Butt-welding is possible by using "Autogal." Butt-welded plates show a tensile strength of 90% of the base plate. Machining of the alloy is easy with high speed. The tensile properties differ somewhat from those of MG 7. The following data are given:

	Yield Point lbs./in.²	Tensile Strength lbs./in.²	Elongation %
Pressed Semi-products	21300-28400	44100-49800	16-22
Soft sheets	21300-25600	44100-51200	16-22
Hard sheets	42700-51200	54000-61200	4-9
Medium hard sheets	.....	49800-56900	6-14

Effect of Annealing on the Torsion Strength of Cast Steel. (Einfluss des Glühens auf die Drehschwingungsfestigkeit von Stahlguss.) B. GARRE & E. GRATHOFF. *Stahl und Eisen,* Vol. 52, May 19, 1932, page 493.

Cast steel containing 0.18% C, 0.25% Si, 0.4% Mn, 0.07% P and 0.07% S was tested after 20 minutes annealing at various temperatures. Results are tabulated herewith:

Annealing Temp. °C.	...	500	700	800	900	1000
Torsion Strength kg./mm.²	10.0	10.6	10.8	11.0	14.0	15.0
Increase %	0	6.0	8.0	10.0	40.0	50.0
Tensile Strength kg./mm.²	38.3	39.3	40.5	40.8	43.0	43.7
Increase %	0	2.6	5.8	6.5	12.3	14.1
Torsion Strength / Tensile Strength	0.26	0.27	0.27	0.27	0.32	0.34
Elastic Limit kg./mm.²	19.6	20.6	20.2	21.0	25.4	25.6
Increase %	0	5.1	3.1	7.1	29.6	30.6
Elongation %	15.9	16.7	24.6	24.3	22.7	25.4
Increase %	0	5.0	54.7	52.8	43.1	59.8
Notch Strength mkg./cm.²	1.29	1.26	1.33	1.40	4.74	5.97
Increase %	0	-2.3	3.1	8.5	267.5	363.0
Brinell Hardness	115	112	113	114	117	121
Increase %	0	-2.6	-1.7	-0.9	1.7	5.2

Develops Chrome—Vanadium Steel with Good Properties for Nitriding. *Steel,* Vol. 90, Feb. 1, 1932, page 37.

The properties and advantages of a new Cr-V nitriding steel containing 0.50-2.50% Cr, 0.30-2.00% V and up to 0.70% C are discussed in technical bulletin No. CV-1, entitled "Chrome-Vanadium Nitriding Steel," issued by the Electro Metallurgical Co. of New York. JN (3)

Black Heart Malleable Fittings. (Schwarzguss-Fittings.) W. HARTUNG. *Gas und Wasserfach,* Vol. 75, May 7, 1932, pages 359-362.

10 The author advises the use in Germany of black heart malleable instead of white heart malleable for fittings. In the discussion the opinion of the author as to a greater economy of black heart malleable for German conditions is refuted. GN (3)

The Technical Treatment of Pulverized Carbonyl-Iron by the Sintering Process. (Die technische Verarbeitung von pulverförmigen Carbonyleisen nach dem Sinterverfahren.) F. Duftschmidt, L. Schlecht & W. Schubardt. *Stahl und Eisen,* Vol. 52, Sept. 1, 1932, pages 845-849.

Report of Oppau Research Laboratory of the I.-G. Farbenindustrie. The manufacture and use of powdered metals and metallic molded articles prepared by the sintering process is a comparatively new field of progress. Carbonyl Fe, especially, lends itself to this newly-developed process. Two properties make carbonyl Fe so suitable, (1) unusually high compressibility of the powder, and (2) its uniformly distributed amounts of C and O. Content of O_2 in carbonyl Fe powder should run from 1 to 2%, and C about the same. The sintering, carried out at 1100° C. for 4 hrs., produces a carbonyl refined Fe material of very high deep drawing qualities. Erichsen indentation tests show this material to be superior to Cu. Carbonyl Fe alloys may be produced similarly. The alloying constituents desired must be added in powdered form to the carbonyl Fe before sintering. The powdered alloys desired may be added either in their metallic state or as oxides. Any type of heating furnace may be used for the sintering, since it is not necessary to maintain a specially protecting atmosphere. The C and O in the carbonyl Fe are converted, by the reactions taking place during the sintering, into CO and CO_2. The mechanical and magnetic properties of pure carbonyl Fe are given as follows:

Elastic limit	11 to 17 kg./mm.²
Tensile strength	20 to 28 kg./mm.²
Elongation	40 to 30%
Brinell hardness	56 to 80
Modulus of elasticity	2,070,000 kg./cm.²
Notch toughness at 20° C. (Dimensions of sample 10x10x10 mm., fracture cross-section 10x5 mm., notch diam. 1.3 mm.)	16 to 20 mkg./cm.²
Conductivity	0.1 x 10⁻⁴
Temperature coefficient of electrical resistance	0.65
Coercive force	0.08 gauss
Permeability μ_o	3,000
Permeability μ_{max}	20,000
Remanence	6,000
Magnetic saturation	22,000

Low-carbon Steel. H. B. Pulsifer. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 347-377.

Includes discussion. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 298. (3)

Hollow Drill Steel. Roy H. Davis. *Canadian Mining Journal,* Vol. 52, Aug. 1932, pages 356-359.

The design of the bit and the efficiency of the heating and hardening have a direct bearing on the drilling performance. The proper temperature for forging depends largely upon the speed of the sharpener and the operator's skill. Forging should be completed as close as possible to the critical temperature. It must be completed before the lower limit of the critical temperature is reached. A table shows the % weld life on samples of drill steel that have been used until a third failure has occurred. They show that it is not economical to weld up broken steel drills. WHB (3)

The Magnetic Properties of Perminvars. (Ueber die magnetischen Eigenschaften der Perminvare.) H. Keuhlewein. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern,* Vol. 10, Mar. 1931, pages 72-88.

The property of the perminvar materials—that is the constancy of the original permeability up to comparatively high magnetizing fields—which makes them so valuable in the construction of instruments is not yet fully explained. The following results can be stated as certain: (1) The different shapes of the hysteresis loops of perminvars all form a continuous series; (2) an increase of the perminvar character in the Elmen perminvar range can be obtained either by a greater content of Co or by annealing at higher temperature; (3) hysteresis loops of perminvar character can be obtained only if the cooling after annealing goes on very slowly; (4) in the system Fe-Ni-Co another perminvar range exists besides that of Elmen which lies very close to the Fe-Ni series; (5) the more pronounced the perminvar character of an alloy is the more difficult it is to demagnetize it; some kinds can be demagnetized only by annealing. 7 references. Ha (3)

The Relation of the Magnetic Properties, especially of the Coercive Force, to the Structure of Alloys and the Development of New Kinds of Magnetic Alloys. (Ueber die Beziehungen der magnetischen Eigenschaften, insbesondere der Koerzitivkraft zum Gefügeaufbau der Legierungen und die Entwicklung neuartiger Magnetlegierungen.) Werner Köster. *Zeitschrift für Elektrochemie,* Vol. 38, July 1932, pages 549-553.

2 important kinds of magnetic properties of metals are represented by a very narrow and a very wide magnetization loop. Homogeneous solid solutions produce the first type, heterogeneous alloys, the second type. In the latter alloys form and size of the structural elements, in addition to the quantity, are determining. The finer the distribution the more difficult becomes the reversal of magnetization. A very fine and uniform distribution can be obtained by precipitation of a phase dissolved in excess during tempering; this treatment can be applied to all ferromagnetic alloys for which the solubility of a phase existing at room temperature for another type of crystal increases with increasing temperature. The magnetization loop is widened to a maximum during the precipitation of the crystal dissolved in excess and is then narrowed again. The regularities observed for Fe-C alloys were confirmed for many other systems of alloys. By systematic experiments and evaluation of the diagrams of state new kinds of magnetic alloys could be developed, containing W, Co, Mo, etc. The heat treatment to develop the best results is given for every case. Ha (3)

The Notch-Toughness of high-grade Structural Steels. (Beitrag zur Kerbzähigkeit hochwertiger Baustähle.) F. Roetscher & M. Fink. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Feb. 20, 1932, pages 173-177.

The mechanical properties of 5 (German) structural steels and their compositions are given; the notch-toughness was determined in annealed and aged condition in the temperature range from −190° to +500° C. The measuring methods are described. Thomas and open-hearth steel in general show the same behavior but the latter has a better performance at lower temperatures and is less sensitive to aging and cold working than Thomas steel. The notch-toughness of all 5 steels drops at −180° to −120° C. below 1 mkg./cm.² Cu-Mn-Si steel is superior to open-hearth steel at temperatures from −100° to −10° C. Ha (3)

High Capacity Free Cutting Steel for Peak Requirements. (Hochleistungsautomatenstahl für Spitzenleistungen.) F. Schmitz. *Zeitschrift für wirtschaftliche Fertigung,* Sept. 1932, page We 16.

Properties and application of 3 new free cutting steels are discussed. Lardo-N with about .20% S and tensile strength of 45-60 kg./mm.² is a rimming steel to be machined with cutting speeds of from 70 to 85 m./min. Since rimmed steels tend to ingot segregation Lardo-Extra (S about .20%) was developed which is free from this defect but cuts only with 50-60 m./min. Lardo Superior contains between .35-.40% S, cutting speed in as delivered state 60-80 m./min., in drawn state 70-90 m./min. The latter steel has excellent machining properties, is best fit for case carburizing and has tensile properties not inferior to steel St. 16.61. GN (3)

New Development of Chromium-Tungsten Steel for Oil-Refining Service. V. T. Malcolm. *Transactions American Society of Mechanical Engineers,* Vol. 54, Mar. 30, 1932, Petroleum Mechanical Engineering, pages 15-25.

A series of tests are described in the development of properties required of a steel for high-temperature construction and service as used in oil-refining service. Besides strength and corrosion resistance factors which must be considered are thermal expansion, thermal conductivity, resistance to abrasion, scaling and oxidation. A Cr-W steel was tested in these respects and gave very satisfactory results. Ha (3)

Quality Cast Steel. (Qualitätsstahlguss.) Adolf Lincke. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 24, 1932, pages 283-284.

After a brief survey on the production of quality cast steel in the acid and basic open hearth furnace the author describes a special method for making quality steel in the Bessemer converter. In order to decrease the S content in the Bessemer charge, the cupola has a basic lining and the pig Fe is melted down in the cupola with a highly basic slag. The P content in the cupola charge is chosen as low as possible. Steel made according to this process shows, for instance, the following composition: C: .25%, Mn: .80%, P: .03-.04%, S: .01-.04%. Tensile strength: 64000-78200 lbs./in.², elongation: above 24%, reduction of area: up to 30%. The results of practical charges and tests are tabulated. There finally is emphasized the importance of the electric furnace for quality steel production. GN (3)

The Yield Point of Mild Steel. C. W. MacGregor. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Applied Mechanics, pages 187-200.

The yield point of mild steel has been investigated under different conditions of the test piece, velocity of stressing, type of head, different kinds of cross sections and grooves on the surface. Small scratches and grooves perpendicular to the bar axis do not appreciably affect the upper yield point, but grooves placed at 45° to the axis of the bar result in a quite different shape of the strain-stress curve and reduce the upper yield stress greatly. Results are shown in detail. Ha (3)

Nickel-chromium-silicon Cast Irons. A. L. Norbury & E. Morgan. *Iron & Steel Institute, Advance Copy* No. 9, Sept. 1932, 14 pages.

A new austenitic cast iron named "Nicrosilal" that has exceptional resistance to scaling and growth was developed. It contains 18% Ni, 6% Si, 2% Cr, 1.8% total C, and 1% Mn. The iron is ductile and not inclined to crack on sudden heating or cooling. It differs from "Ni-resist" chiefly in that it contains more Si. It can be melted in the cupola and cast into sections less than ⅛" thick. It is easily machinable and has an electric resistance of 160 microns/cm.³ Its corrosion resistance can be increased by the addition of Cu. The results of many mechanical, dilatometric, and growth tests on irons containing various amounts of Si, Ni, Cr, and C are given. From these results it was concluded that the most satisfactory iron had the composition listed above. JLG (3)

Iron from Cupola Furnace Comparable to Steel. (Fonte au Cubilot Comparable à l'Acier.) *Revue de Fonderie Moderne,* Vol. 26, Aug. 25, 1932, pages 276-277.

Fe with only 2.5% C was obtained which showed a behavior almost like steel or malleable Fe, in structure as well as in physical properties. Ha (3)

Impact Tests on Notched Bars. (Essais au choc sur barreaux entaillés.) R. Zoja. *International Association for Testing Materials, Zurich Meeting, 1931,* Vol. 1, 1932, pages 356-364.

The specifications of the Italian Railways as to impact figures on different classes of steel are listed. For the study of aging embrittlement after deformation, instead of deforming an impact specimen by compression as has been done by other workers, Zoja suggests subjecting it to impact in the Charpy machine sufficient to deform it to the desired degree but not to break it, then age it by heating to 200°-300° C. and break it in the Charpy machine. Plotting kg.-m. work of fracture against percentage deformation and using enough specimens, characteristic curves are obtained. In typical curves shown, one readily aging steel begins to show 2 sets of values, one high and one low, belonging to 2 different curves of opposite slope, at only 3% deformation, while a difficultly aging steel only begins to show this dispersion at 30% deformation. The slope of the curves for brittle behavior is quite similar in both cases, but those for tough behavior are very different. HWG (3)

Heat-Treatment of Chrome-Moly after Welding. WILMER E. STINE. *American Machinist*, Vol. 76, Feb. 4, 1932, page 163.

Cr-Mo steel used for airplanes has approximately the following analysis: C 0.25-0.35; Mn 0.40-0.60; P 0.040 max.; S 0.045 max.; Cr 0.80-1.10; and Mo 0.15-0.20. The U. S. Army requires a minimum tensile strength of 125,000 lbs./in.² Welding tends to reduce the tensile strength. This was overcome by heat treating as follows: normalize to 1,650°-1,750° F. and cool slowly in furnace below red heat, heat to 1,550°-1,625° F. and quench in light oil, draw at 950° F. Tables are given showing the increase in strength due to heat treatment. The increases are generally more than double. RHP (3)

The Magnetic Properties of Iron, Nickel, Cobalt and a few Alloys at higher Temperatures. (Die magnetischen Eigenschaften von Eisen, Nickel, Kobalt und einigen Legierungen bei höheren Temperaturen.) H. KUEHLEWEIN. *Wissenschaftliche Veröffentlichungen aus dem Siemens-Konzern*, Vol. 11, Mar. 1932, pages 124-140.

Fe, Ni, Co and several alloys, namely 1.95% Fe, 5% Ni, 2.90% Fe, 10% Ni, 3.45% Ni, 30% Fe, 25% Co, 2.50% Fe, 50% Co and some hexagonal Co alloys, were magnetically examined at high temperatures. The existence of 2 Curie points could be confirmed for Fe, Ni and one cubic face-centered Fe-Ni-Co alloy; the paramagnetic Curie temperature is here always higher than the ferromagnetic Curie temperature. The reverse could not be found; the magnetic transformation is identical with the A_3 transformation. It can be demonstrated on hexagonal Co alloys that the transformation of the hexagonal lattice in face-centered cubic lattice and vice versa can be influenced by an exterior field. Ha (3)

Malleable Cast Iron. (Der Temperguss.) E. SÖHNCHEN. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Mar. 20, 1932, pages 115-117; May 1, 1932, pages 178-180; May 29, 1932, pages 216-217.

This is a comprehensive review of the properties of malleable cast Fe. The first installment deals with the tensile properties and refers to the tensile test, the bending test, hardness and notch toughness. The tensile strength, and elongation of German malleable cast iron made according to the various methods are given as follows:

Type of malleable cast iron	Tensile Strength lbs./in.²	Elongation %
White heart malleable:		
Cupola (A)	66 000	5.4
Cupola (B)	60 150	6.3 (transition to black heart)
Crucible	61 300	6.3
Open hearth	61 150	5.9
Open hearth	74 250	3.3 (for special purposes)
Electric furnace	71 750	6.5 (partially black heart)
Black heart malleable:		
Reverberatory furnace, oil fired	51 750	12.0
Open hearth furnace	56 600	11.1
Cupola	54 050	10.9
Brackelsberg furnace	63 150	19.1 (special malleable)

The second installment discusses the technological properties of malleable cast Fe. A great disadvantage of black heart malleable is its sensibility to temperature which is already observed in temperature ranges between 400°-500° C. Difficulties are encountered in hot galvanizing black heart Fe (at about 500° C.). The casting becomes hard and brittle just at these temperatures. This difficulty can be eliminated by heating to 650 and quenching before hot galvanizing. The pronounced temperature dependence of black heart malleable can be utilized for an improvement of the otherwise low tensile strength and low resistance to wear. This is done by a suitable heat treatment, heating to about 760° C. and subsequent quenching in oil or water so that any property desired can be obtained. The hardenability of white heart malleable depends on the C content. Black heart malleable can be better riveted than white heart malleable. Welding of malleable cast Fe needs great experience and skill. Welding practice and results are discussed. Machining offers no difficulties. Data on specific gravity and shrinkage are given. The 3rd and last installment of the author's paper on the properties of malleable cast Fe deals with special physical and chemical properties. Since malleable cast Fe has a low magnetic hardness it is used in electro-machine construction for armatures, pole shoes, etc. Malleable cast Fe has excellent properties against chemical attack (water, gases, influence of the weather). The paper finally deals with the effect of C, Si, Mn, P and S on the mechanical properties. A low content of total C favorably affects the properties as is shown for the notch toughness in the table below. A maximum of toughness, elongation and machinability is attained when practically no combined C is present. Si favorably affects the malleablizing process and increases the density. Though P impairs the toughness this effect is the less pronounced the lower the content of combined C. A moderate S content hinders the precipitation of graphite in the raw casting and retards the formation of temper carbon during the malleablizing process. The impairing effects of a higher content of S should not be overestimated.

Notch Toughness in Dependence on Combined Carbon

Notch Toughness mkg./cm.²	Total Carbon %	Temper Carbon %	Combined Carbon %
17.0	.71	.49	.22

GN (3)

Malleable Iron Castings, Their Design and Physical Properties. J. H. LANSING. *Journal Society of Western Engineers*, Vol. 37, Apr. 1932, pages 104-109.

Outstanding properties of malleable Fe include: (1) the structural composition of the original hard Fe castings consists of pearlite and cementite, (2) primary graphite is rarely present, due to a better adjustment of the C and Si content, (3) the castings are poured at a temperature permitting sharp definition and an excellent surface, as well as affording freedom from occluded gases, (4) the white Fe castings are coarse-grained, hard and brittle, and as a necessary subsequent part of this manufacture they are subjected to a heat treatment or conversion process whereby the original characteristics are changed to the exact opposite—tough and strong, (5) the structural composition of the annealed castings is made up of a matrix of ferrite throughout which are uniformly distributed nodules of free C, (6) the finished product is tough, ductile, highly shock-resistant, and due to the temperature at which the conversion process is carried through, and as a result of the slow cooling from this temperature, the castings are fine-grained and free from internal strains, (7) these inherent properties made for ease of machining, and (8) due to their structure and freedom from strains, malleable Fe castings have remarkable corrosion-resistant properties. Average properties of higher strength malleable Fe are tabulated. 17 factors to be considered in the designing of malleable Fe castings are listed. WHB (3)

A New Automotive Steel. *Vancoram Review*, Vol. 3, Apr. 1932, pages 51-54.

A composition named "Normalloy" containing Mn in proportions higher than are usual in simple C and most low-alloy steels and containing in addition effective though small amounts of V, and in some instances other elements, is distinguished by its most satisfactory adaptation to normalizing treatment. This steel is used for locomotive and similar forgings of large size in which high strength and dynamic properties are required and for which quenching and tempering operations can not very well be carried out on account of mass or are not permitted due to residual quenching stresses. Such steel of an average composition of 0.47 C, 0.75 Mn and 0.16 V in forgings showed the following results:

No.	Yield Point lbs./in.²	Tens. Str. lbs./in.²	Elong. % in 2"	Red. area %	Izod ft.-lb.	Brinell Hardness
1	73,900	120,250	19.5	48.4	12.0	235
2	77,200	113,150	20.0	47.6	16.5	219
3	76,700	117,700	19.5	46.1	12.5	237
4	79,700	119,350	20.0	45.6	12.8	237

The same uniformity was also shown in the microphotographs of the grain structure, and in samples of thick pieces (7") whether taken from core or edge. Ha (3)

Theory and Practice. (Wetenschap an techniek.) A. VOSMAER. *De Gieterij*, Vol. 6, June-July 1932, pages 64-65.

Although cast iron may be considered as an inferior metal it constitutes a third of the world production of ferrous metals and its cheap price and its ease of manufacture make it a very desirable metal in many cases where more expensive metals would present better qualities. The relatively low fusion point, the great workability, the ease of molding makes it very practical. Besides the common cast Fe a special grade called "hartguss" has been in use for years where hardness is desired. But since the rapid development of the special steels (Ni, Ni-Cr, high Si, Cr, Mn) the effect of adding the same metals to cast Fe have been considered. The author refers first to the Si additions which increase the acid resistant qualities by the separation of C in graphite form while additions of Mn would have the opposite effect. He first shows that at about 10% Si the cast Fe called by different trade names (Tantiron, Duriron, metalline, corosiron, etc.) is very highly acid resistant. The Ni and Cr additions are then examined and first Ni additions are shown to have an effect similar to Si though not as simple. Certain proportions of Si destroy the favorable effect of Ni additions. The amount of Ni must be greater than 0.5% to show its effect. At 3% Ni the metal has a very fine structure, from 3 to 10% the hardness increases rapidly to become a maximum at 10% where the metal has a Brinell hardness of 300 instead of the normal Brinell number of 150 to 180. At about 20% Ni the metal is practically resistant; it must be noted here that in the Ni steels the same result is only attained when 25% Ni is used, to give it the "rustless" character. It is also interesting to note that for low percentages of Ni the cast Fe presents remarkable alkali resistant qualities while more than 5% are better suited for acid resistant cast irons. The simultaneous addition of Cr and Ni makes the metal yet more acid resistant but due to the scarcity of the Cr ores this material is very expensive. Another fact makes this yet worse, the addition of Cr to cast Fe to become effective must be higher than for special steels. While the percentage of Ni is smaller by 5% than for rustless steel the percentage of Cr must be higher than 30% to enhance the special qualities while for steel lower percentages are sufficient. The *Krupp'sche Monatshefte* for Dec. 1931 shows that more than 30% are absolutely necessary. Additions of a certain % of Cu with Cr and Ni seems to better the quality at a lower cost. Time will tell about the future of all these special cast irons in competition with special steels. A very remarkable metal of which the author gives the composition but not the trade name would be composed as follows: 2.3% C, 1.4% Si, 0.4% Mn, and 34.2% Cr which shows the very special characteristics that while all other ferrous alloys show at 500° C. about half the traction resistance shown at 20° C., this alloy shows 41.1 kg./mm.² at 20° C. and 46 kg./mm² at 500° C. At 600° C. however this resistance decreases to 28.5 kg./mm.². Its hardness is 300 Brinell. The heat resistant qualities as well as the alkali, acid and salt resistant qualities referred to are mostly interesting to the chemical industry. It is only regrettable that while 15% Cr imparts these special qualities to steel, 34% are necessary for cast Fe. MPW (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Study of the Corrosion of Iron and Its Alloys. (Etude sur la Corrosion du Fer et de ses Alliages.) T. Levoz. *Revue de Fonderie Moderne,* Vol. 26, June 10, 1932, pages 188-192.

In order to produce an iron or iron alloy which can be used as a base for rustless steel the primary material should be as free of O as possible. The author describes a cupola furnace of his invention where he can produce such Fe and steel without O or other gas enclosures. He distinguishes between plants which use only secondary or remelts and those which melt the raw materials, and gives the composition of the charges for the furnaces and for the converters, and also the temperatures at which to work. The addition of 0.3 to 5% Cu improves the quality of the Fe. Side blowing in Thomas converters is advised. Although Cu is a good anti-corrosive, Cu and Fe do not combine easily and alloy often rather irregularly. Temperatures higher than 1650° C. should be used and the customary reducing agents employed. With this iron, alloys with Ni, Cr, U, W, Co can easily be obtained. Ha (4)

Corrosion Resistant Alloys of the Stainless Type in Use and Fabrication. T. Holland Nelson. *Year Book of the American Iron & Steel Institute,* 1931, pages 171-217.

See *Metals & Alloys,* Vol. 2, Nov. 1931, page 246. (4)

A Peculiar Type of Corrosion in Chrome-Nickel Austenitic Steels (Un mode particulier de corrosion des aciers austenitiques au chrome-nickel). A. Sanfourche & A. Portevin. *Comptes Rendus,* Vol. 194, May 17, 1932, pages 1741-1743.

The authors point out that austenitic steel of the 18/8 type, which has been shown to be unaffected by cold phosphoric acid (*Comptes Rendus,* Vol. 192, 1931, page 1563, and Vol. 193, 1931, page 53) is rapidly corroded if this acid contains HCl even in small amounts. Systematic study of the effect of this factor has brought out certain interesting peculiarities. In general, it requires less HCl to cause attack when concentrated H_3PO_4 is used. In 100 cc. of 35° Bé solution 0.5 cc. of HCl suffices to start an accelerating action which terminates in the complete destruction of the alloy. This, however, only corresponds to the very small ratio HCl/H_3PO_4 of 1/625, which shows that HCl is continually liberated as a result of the reaction of the chlorides already formed with the H_3PO_4. Another point brought out is that with low concentrations of phosphoric acid (30° Bé) the surface condition of the sample appears to have no influence upon the attack; this, however, is no longer true with 53° Bé acid. The behavior of austenitic steel in 60° Bé acid containing 0.5 cc. HCl (HCl/H_3PO_4 = 1/790) has been studied very closely, using as standards both the loss of weight of the alloy with time and the variations of its potential relative to a hydrogen electrode submerged in the corroding medium. 3 periods of corrosion were distinguished by this means—(1) a period of initial passivity during which the e.m.f. increased to 0.10-0.12 v., while the loss in weight of the sample was almost nil; (2) a period during which the e.m.f. rose precipitately to 0.22-0.24 v., then fell fairly quickly to 0.20-0.22 v., and finally, more slowly, to 0.18-0.19 v., while the loss in weight of the steel increased linearly relative to time; (3) a period during which attack ceased just as abruptly as it began; this period opened with a sharp drop of potential from 0.18-0.19 to 0.12-0.14 v. The results of these studies are embodied in a diagram in which, however, the time scale is not graduated, since the time at which the second period commenced varied with the state of the sample. In samples previously pickled in HCl the initial period of passivity was 2 hr., while in a sample previously sandpapered the initial period of passivity was 6¾ hr. The second period, that of attack, did not appear to be related in length of time to the initial state of the sample; it varied in length from 24 to 40 hr. The loss of weight per sample per hour, however, was definitely affected by the condition of the sample. In the case of sanded samples the loss in weight was 0.55 mg./cm.^{2}; in the case of pickled samples, 0.85 mg./cm.^{2}. At the commencement of the third period the solution assumed a strong green color and the alloy became coated with a black layer of double carbide of Fe and Cr. The formation of this carbide is opined by the authors to be responsible for the cessation of attack of the steel, its appearance and that of the second period of passivity coinciding. The authors noted that if attack of the samples was interrupted, the samples being then washed and dried, passivity was once again conferred upon them. The paper closes with a brief résumé of the authors' findings. OWE (4)

The Painting of Railway Structures and Equipment. H. E. Smith. *Industrial & Engineering Chemistry,* Vol. 23, Dec. 1931, pages 1343-1346.

Buildings, steel bridges and freight cars, passenger cars and locomotives are discussed from the standpoint of protective and decorative coatings. Some of the materials used for coating the steel work are listed. MEH (4)

Recent Progress in Rust-Proofing Steel Pipes and in the Protection of Pipe Joints. (Fortschritte in Stahlrohrisolierung und im Schutz der Rohrverbindungsstellen.) Weckwerth. *Das Gas- und Wasserfach,* Vol. 75, Jan. 23, 1932, pages 69-73.

Investigations made by the Vereinigte Stahlwerke show that pipes with protective covering are able to resist the highest stresses and most severe working conditions. In general, it may be said that the results indicate that pipes with this protective insulation will resist every kind of injury that may be sustained during transportation, operation and storage. After a research covering a period of 4½ years, the Mannesmann-Roehrenwerke succeeded in finding an anti-rust agent to resist chemical and mechanical attacks by acids, alkalies, hydrocarbon gases, salts and other elements found in the soil and known for their corrosive effects. MAB (4)

Machine Tests Corrosive Action. *Power,* Vol. 75, May 3, 1932, page 661.

An apparatus for alternately immersing a solid in a liquid and exposing it to the air is briefly described and pictured. AHE (4)

UNIVERSAL CORROSION-RESISTANT ALLOY

supplied as rough or finished castings

Particularly effective against the sulphur acids and compounds, ILLIUM likewise withstands other corrosives, both acid and alkali, to a degree equalled by few materials. Also resistant to heat, wear, impact and torque. It machines readily, takes high polish, is easily welded.

ILLIUM has been in successful use for more than 15 years. Its chemical and physical characteristics are known. Its advantages and limitations clearly defined. Its record is proof of its value.

RECOMMENDED FOR

Agitators	Filter Parts
Bobbins and Holders	Instrument Cases
Bombs	Kettles
Bolts and Nuts	Machine Parts
Buckets	Nozzles
Crucibles	Pipe Fittings
Dipping Baskets	Pump Parts
Fans	Racks
	Valve Parts

and other similar items

Do you have a corrosion problem in some process or in equipment which you sell? Let us quote from your patterns or drawings, or work with you in designing ILLIUM parts to eliminate the trouble. At least *investigate* ILLIUM'S possibilities. The coupon below is for your convenience.

Corrosion Protection by Chromium Plating and Testing Methods Therefor. (Korrosionsschutz durch Verchromung und dessen Prüfungsmethoden.) H. Leiser. *Metallwaren Industrie und Galvano-Technik,* Vol. 29, Oct. 1, 1931, pages 431-432.

Cr itself does not warrant any rust protection. Flawless, thick intermediate layers are required. The total thickness of all layers should be 0.025 mm. Testing methods for absence of pores are considered, namely (1) "Ferroxyl" reagent, (2) Cu plating in acid electrolyte at low currents. Cu is deposited in pores and flaws. Spots which are not Cr plated can also be recognized by dipping the object into a solution containing 150 g. $CuSO_4$ + 10 cc. H_2SO_4/ 1,000 cc. H_2O. The salt spray test, which might also be employed, is described. EF (4) — 1

Corrosion Protection of Marine Turbines. (Über den Korrosionsschutz von Schiffsturbinen.) H. Maseille. *Farben Zeitung,* Vol. 36, May 16, 1932, page 1476; *Peintures, Pigments, Vernis,* Vol. 8, Mar. 1931, pages 1453-1457. — 2

The main causes of the corrosion of marine turbines, are the presence of moisture, salt water and heat while standing idle. In addition to this, local currents occur due to the presence of different structural metals. Utilization of corrosion resistant alloys did not prove successful. The French Navy obtained some good results on paints containing Al or graphite. The best way of preventing corrosion is to keep salt water out of the turbine and to keep the latter dry during periods of idleness. EF (4)

From Empirical to Fundamental Facts of Corrosion. (Vom Empirischen zum Grundsätzlichen beim Einzelfall der Korrosion.) G. Masing. *Feinmechanik und Präzision,* Vol. 40, Mar. 1, 1932, pages 53-54. — 3

Investigations on Corrosion by Water Impingement. (Untersuchungen über Korrosion durch Wasserstoss.) J. Ackeret & P. de Haller. *Schweizerische Bauzeitung,* Vol. 98, Dec. 12, 1931, pages 309-310.

Preliminary report of tests on the resistance of materials to mechanical-hydraulic erosion. According to a method by Honegger (*B B C Nachrichten,* Vol. 14, 1927, page 95) the sample is attached to a rotating disk and thrown against a water jet parallel to the wheel axis. Jets 1 cm. in width were used. At a jet velocity of 50 m./sec. medium hard open hearth steel was considerably eroded after 5,000,000 impacts. The investigations give an interesting outlook on the causes of erosion by real cavitation. GN (4) — 4

Corrosion of Water Heaters. (Rosterscheinungen in Boilern.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Oct. 19, 1932, page 559.

Discussion between Bauerfeld and the authors of the former publication on the above subject in *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Sept. 4, 1932, pages 465-466. Bauerfeld thinks proper Zn coating of prime importance for the avoidance of such failures, but Daeves and Grosschupff do not believe this to be correct. GN (4) — 5

Remarkable Damage of the Walls of a Boiler Through Feed Water. (Bemerkenswerte Beschädigungen der Wandungen eines Dampfkessels durch das Speisewasser.) *Zeitschrift des Bayerischen Revisionsvereins,* Vol. 36, Feb. 29, 1932, pages 36-37.

The heavy corrosion of the boiler walls was found to be due to the feed water having been polluted by HCl. GN (4) — 6

Thinly Liquid Aluminum. (Dünnflüssiges Aluminium.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Sept. 25, 1932, page 508.

Brief description of a highly effective rust preventer, and protection against flue gases, in which Al flakes are mixed with a binding compound (composition not given). The new coating compound "Storal" which also has excellent properties against friction, pressure, shock, etc. combines elasticity with hardness. Marketed by Storalindustrie, Grevenbroich, Germany. A Modified Impingement Corrosion Apparatus. H. W. Brownsdon & L. C. Bannister. *Institute of Metals, Advance Copy* No. 608, Sept. 1932, 8 pages.

The sample is immersed in the test solution and a jet of air blown on it at a given angle. The distance of the jet from the sample, the dimensions of the jet and the pressure of the gas must be carefully controlled. Under such conditions reasonable and reproducible results are obtained. A 500-hr. test is used. The depth and area of the resulting pit afford the best gage of corrosion. Preliminary results on several Cu-base alloys are given. JLG (4) — 8

A Method for the Measurement of the Dissolution of Metals in Salt Solutions. L. Whitby. *Transactions of the Faraday Society,* Vol. 28, May 1932, pages 474-478.

The method is to analyze samples of gas periodically removed from above the corroding liquid and to determine the volumes of O_2 absorbed and of H_2 evolved. Mg when dissolving in very dilute NaCl solutions does not absorb appreciable quantities of O_2. By this method serious errors are not probable. PRK (4) — 9

A Case of Severe Corrosion in the Upper Drum of a Water Tube Boiler. (Erhebliche Ausrostungen in der Obertrommel eines Schrägwasserrohrkessels.) *Zeitschrift des bayerischen Revisionsvereins.* Vol. 36, July 15, 1932, pages 159-160.

Considerable corrosion was observed in the water space of the boiler drum inspected. Rust grooves and pits up to 4 mm. deep were found, particularly near the plate joints. The remedies are described. GN (4) — 10

Soil Survey Methods are Essential Part of Any Corrosion Survey. Scott Ewing. *Oil & Gas Journal,* Vol. 30, Apr. 21, 1932, pages 42-44.

A paper presented before the American Gas Association Distribution Conference. A comprehensive summary of methods of soil corrosion determination. A rough relation is shown between corrosiveness and resistivity for alkali soils and between acidity and corrosiveness for acid soils. Some soil series are uniform in their properties and corrosiveness while others are not. The corrosiveness of the soil cannot be determined with any precision by any one of these methods. All factors must be considered. VVK (4)

Controlled Data from an Immersion Test. R. F. Passano. *Preprint* No. 44, June 1932 meeting, *American Society for Testing Materials,* 7 pages.

In an immersion corrosion test, in a device not described, the author maintains the temperature, oxygen concentration, velocity, type of water, area of specimen, and surface condition of specimen constant varying only the time of test. By the use of modern statistical theory it was shown that, with these variables under control, the resulting data did not differ significantly and that the average loss of weight was apparently proportional to the logarithm of time over the interval investigated. 2 references. VVK (4)

The Topochemistry of Corrosion and Passivity. I. Attempt to Develop the theoretical Principles. (Zur Topochemie der Korrosion und Passivität. I. Versuch einer Darstellung der theoretischen Grundlagen.) Erich Pietsch & Edith Josephy. *Zeitschrift für Elektrochemie,* Vol. 37, Nov. 1931, pages 823-838.

The theories so far adduced to explain the corrosion phenomenon are reviewed and discussed and the shortcomings pointed out. For a new explanation it is assumed that corrosion consists primarily in an adsorption at the active discontinuities of the surface which would mean a heterogeneous catalysis. This is explained by the quantum-mechanical theory. Passivity and overvoltage can be explained on the same basis, and it is shown that the adsorption potential plays an important part in corrosion. Ha (4)

Method of Preventing Corrosion of Air Preheaters. (Verfahren zur Vermeidung der Korrosion in Taschenluftvorwärmern.) P. E. Quintes. *Die Wärme,* Vol. 55, Jan. 16, 1932, pages 45-46.

The temperature conditions prevailing in commercial air preheaters are analyzed and devices are suggested to prevent local supercooling of the waste gases below the dew point which results in a severe corrosion attack due to the presence of SO_2. EF (4)

Tests Made to Prolong Life of Paint on New Water Tanks. D. W. Johnson. *Water Works Engineering,* Vol. 85, Aug. 24, 1932, pages 1010-1012.

Experience has shown that unless care is exercised in choice of paint material and workmanship employed on the first paint job, the coating will fail within 2 years. Steel used in constructing a tank should be free from mill scale and rust and preferably should receive a priming coat at the mill. Should rust or scale be present, before fabricating the steel should be sand blasted or thoroughly brushed and scraped. CBJ (4)

The Anodic Treatment of Aluminum. E. Joyce. *Monthly Review, American Electroplaters' Society,* Vol. 19, Jan. 1932, pages 16-26.

Includes discussion. Paper before Philadelphia Branch Annual Meeting, Nov. 21, 1931. See *Metals & Alloys,* Vol. 3, Oct. 1932, page MA 292. LCP (4)

Corrosion Tests of Light Metals. (Korrosionsprüfungen der Leichtmetalle.) *Schweizerische Technische Zeitschrift,* Vol. 29, Apr. 28, 1932, pages 260-263.

The corrosion tests of light metals and alloys which have been developed by the laboratories of the members of the European aluminum association in coöperation with the "Bureau International d'études et de propagande pour le dévelopement des emplois d' aluminium" are described. In corrosion testing the data accumulated have to take account of the composition and the pre-treatment of the alloy, the dimensions of the specimens and the corrosion apparatus, testing temperature and the suspension of the specimens. Among the abbreviated corrosion tests are described: (1) the HCl test according to Mylius, (2) the gas-volumetric test in HCl, (3) the oxidizing test in NaCl according to Mylius. Among the long time corrosion tests are described: (1) the oxidic tests in NaCl as developed by the Deutsche Versuchsanstalt für Luftfahrt. (2) solubility tests, (3) the salt spray test, (4) immersion tests, (5) alternating immersion tests. GN (4)

The Relative Corrodibilities of Ferrous and Non-Ferrous Metals and Alloys. Part III—Final Report. The Results of Three Years' Exposure at Southampton Docks. J. Newton Friend. *Journal Institute of Metals,* Vol. 48, 1932, pages 109-120; *Engineering,* Vol. 133, Mar. 11, 1932, pages 329-330.

Corrosion of Earthing Conductors. C. W. Glanister. *Electrical Review,* Vol. 111, July 29, 1932, page 160.

After 12 mo. specimens of Cu stranded conductors used as earth connections and Cu plates buried in coke-breeze were inspected. Considerable corrosion was found to have taken place, all of it on the sections surrounded by the coke-breeze. In one case, the 0.075 in.^{2} conductor had corroded completely away. Cu sections which passed through clay were not affected. Opinion is that rapid corrosion was not caused entirely by local action but was probably assisted by earth leakage currents. Cu-C cell is formed by Cu buried in coke-breeze, causing Cu to go into solution. Coke contains NH_3 and NH_4 salts which facilitate corrosion of Cu. Addition of $CaCO_3$ to coke-breeze would protect Cu and prevent rapid corrosion. MS (4)

Corrosion in Highly Stressed Boilers. (Ueber Korrosionserscheinungen an Hochleistungskesseln.) E. Lupberger. *Elektrizitätswirtschaft,* Vol. 31, Mar. 15, 1932, pages 118-119.

Errors in Construction of a Preheater. Cracking in Brass Tubes. (Baufehler an einem Vorwärmer. Rissbildung in Messingrohren.) BERTHOLD BLOCK. *Korrosion,* supplement to *Chemische Apparatur,* Vol. 19, Apr. 25, 1932, pages 13-14.

Several 60-40 brass tubes in a syrup preheater, utilizing the vapor from one effect of an evaporator as heating medium, sprung leaks after a few days of operation. The cracking of the tubes was caused by the combined action of ammonia vapor present in the steam and stresses imposed by poor construction of the supporting sheet. The latter made it necessary to bend the tubes and keep them in tension. Being 60-40 brass, cracking occurred when subjected to ammonia. Better construction and the use of 70-30 brass proved a satisfactory remedy. BER (4) 1

Studies on Stress-Corrosion Cracks in Light Metals. (Untersuchungen über Spannungs-Korrosionsrisse an Leichtmetallen.) P. BRENNER. *Zeitschrift für Metallkunde,* Vol. 24, July 1932, pages 145-151.

A study of the conditions leading to the formation of stress-corrosion cracks in light metals. A number of examples of such cracks is given and illustrated for Al-base and Mg-base alloys. Two Al-base alloys (I. 4.07% Cu, 0.51% Mg, 0.34% Si, 0.61% Mn, 0.39% Fe; II. 4.19% Cu, trace Mg, 1.02% Si, 0.61% Mn, 0.34% Fe) were studied; these alloys differed in the type of corrosion, the first (I) showing no intercrystallization attack and the second (II) pronounced intercrystallization attack. The alloys were given 3 kinds of deformation: elastic, plastic, and plastic plus elastic. The alloys in the deformed state were subjected to corrosive attack in a standard (DVL) salt-spray apparatus. Alloy I showed no tendency towards the formation of cracks under any of the conditions chosen; alloy II undeformed and plastically deformed also showed no such tendency, but when deformed elastically, and plastically plus elastically, formed cracks leading finally to fracture. The time to fracture is determined by the amount of elastic deformation (shown in a graph); the addition of plastic deformation to elastic facilitates the formation of cracks, though plastic deformation alone is ineffective. Stresses of the order of 4 kg./mm.^{2} are effective. It is concluded that crack-formation is a consequence of intercrystallization corrosion, which, however, will obtain only when elastic stresses are present. RFM (4) 2 3 4

Limits of Waste Heat Utilization with Respect to Corrosion of Equipment in Contact with Stack Gas. (Grenzen der Abwärmeverwertung in bezug auf die Korrosion rauchgasberührter Apparate.) WILHELM GUMZ. *Korrosion,* supplement to *Chemische Apparatur,* Vol. 19, Mar. 25, 1932, pages 9-11.

Combustion gases contain different amounts of water from various sources and consequently have various dewpoints. It is essential that the temperature of operation is not carried below the dew point if corrosion is to be avoided. Dangers other than H_2SO_4 corrosion arise when the fuel contains S since flue dust is likely to become hygroscopic and attract water. The construction of any interchanger is important from the viewpoint of gas cooling rate and the consequent rapidity of approach to the dewpoint. The ideal design would permit operation at a uniform wall temperature somewhat above the dewpoint of the waste gas; since this is impossible, a bend free counter current interchanger, using a high flue gas velocity, a low air velocity, and operating at a temperature well above the dewpoint is recommended as an approximate solution to the problem. BER (4) 5 6

Metallurgical Problems Arising from Internal Combustion Engine Valves. J. R. HANDFORD. *Iron & Steel Institute, Advance Copy* No. 4, Sept. 1932, 39 pages.

The requirements for valve steels as given by several engineers are listed and discussed. Many steels that have been used in valves are described, and the functions of the various alloying elements discussed. Scaling tests at 800° and 900° C. of 10 valve steels indicated that most of the steels have a satisfactory resistance to scaling. Specimens of steels of various analyses were held in an oxidizing atmosphere at elevated temperatures for 1000 hr. and their resistance to deterioration at such temperatures determined by microscopic examination and mechanical tests at both low and high temperatures. Due to the complexity of the steels investigated and the number of data obtained it is impossible to summarize the results of these tests here. The causes of valves cracking are discussed. Some experiments with Stelliting valves are described. Stellited valves when properly made and heat treated give excellent results. In general, the widely used valve steels are not attacked by exhaust gases other than those from fuels containing Pb tetra-ethyl. A study of the deterioration of austenitic steels is described. Some of these steels show changes in structure when heated to 600° C. and these changes appear to be similar to "weld decay" in 18-8 stainless steel. JLG (4) 7 8

Acidproof Alloys. (Säurebeständige Legierungen.) *Kali, Erz und Kohle,* Vol. 29, Sept. 10, 1932, pages 142-144.

Survey on the present status of ferrous and nonferrous alloys of high resistance against acids. GN (4)

Causes and Prevention of Corrosion in Gas Heated Water Heaters. (Korrosionserscheinungen im Wasserweg gasbeheizter Warmwasserbereiter — Ursachen und Abhilfe.) *Gas und Wasserfach,* Vol. 75, Sept. 17, 1932, pages 753-758.

Some typical cases of corrosion of gas heated water heaters are described, the results of an examination of 2 heaters are discussed. In the one case corrosion was found to be due to electric stray current. Means of corrosion protection are outlined. GN (4) 9

The Removal of Scale from Water Spaces. *Engineering,* Vol. 133, Apr. 22, 1932, pages 493-494.

Describes tests carried out by Messrs. Mirrlees, Bickerton & Day, Ltd., Stockport, England, in an attempt to find a rapid and safe method of cleaning out the water spaces of Diesel engines. A substance is used called "Mirrlees Inhibitor," a dry powder which when added to HCl reduces the action of the acid on the metal with very little effect on the scale. Graphs are given showing the effect of the addition of the inhibitor and of varying the strength of the acid. When the container used is of brass, bronze, gunmetal, Cu or Sn no inhibitor is needed. If steel or cast Fe is used, the inhibitor should be used to reduce the action of the acid on the metal. LFM (4) 10

Most new developments have a few "bugs"—

and the "bug" in chrome-nickel alloy steels, for use under corrosive conditions, was "intercrystalline corrosion"—a precipitation of the carbides on the grain boundaries resulting in granulation and mechanical failure.

Research showed that if the total carbon content was held to .07% or lower that, for all practical purposes, intercrystalline corrosion was whipped.

Durco Nirosta alloy steels are made in high frequency electric induction furnaces, which is absolute assurance that the carbon is controlled to the analysis desired.

Machinery manufacturers of all kinds selling their products to many different industries are using Durco Nirosta low carbon castings for machine parts exposed to corrosive conditions. Their experience has proved that it pays to use quality products—products that they can back up with their good names.

If you are responsible for determining what shall be used in your own products, you are overlooking something if you don't investigate Durco Nirosta alloy steels. A representative will be glad to call on you, and discuss the application of these corrosion-resisting low carbon alloys to your problem. You may not require them, but it is better to know it than to need them and not know it. The latter condition usually results in sales going to competitors.

The Behavior of Pure Aluminum towards Acids and Bases. (Verhalten von reinsten Aluminium gegen Säuren und Basen.) M. Centnerswer. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 598-603.

Al of 99.95% purity dissolves very slowly in HNO_3 and H_2SO_4. In HCl a measurable rate of solution is obtained only in solutions more concentrated than 2 *N* at 25°. The rate of solution depends on concentration according to the formula $dv/dt = K_nC^n$. The temperature coefficient between 25° and 35° C. is 7.0. In alkalies, pure Al dissolves in the same manner and with the same speed as 99% Al. Pure Al dissolves in dilute NH_4OH. Ha (4)

Chemical Stability of Some Non-ferrous Alloys. (Die chemische Beständigkeit einiger Nichteisenmetall-Legierungen.) W. Claus. *Die Metallbörse,* Vol. 22, Jan. 23, 1932, pages 97-98; Feb. 1, 1932, pages 129-130.

The chemical stability of some metallic substances was measured by the loss in weight in mg./m.²/day with reference to the metallic surface attacked. Data are given for 2 Cu-Sn alloys (93.75 Cu, 6.05 Sn and 90.21 Cu, 9.79 Sn respectively) 1 Cu-Sn-Zn alloy with 88.68 Cu, 6.90 Sn, 4.42 Zn and 1 Cu-Sn-Pb alloy containing 83.92 Cu, 9.58 Sn, 5.94 Pb. The test pieces were cut from ingots and investigated in the as-cast and annealed state. The samples were tested in a specially designed apparatus in which the solution is agitated. The testing time varied between a couple of hours and a period of several weeks. The testing solutions comprised 3% NH_3, 5% HCl, 3% KOH, natural seawater, and 2 and 4% Na_2SO_4 solutions. In general the alloys were attacked severely after 8 hours in NH_4OH and HCl, but proved to be stable in the other solutions applied. A protective layer at the surface of the specimens was noticed in KOH which finally stopped the corrosion attack entirely. The presence of air increased the activity of the NH_4OH and HCl solutions. No differences between the cast and heat-treated samples were found. EF (4)

Corrosion of Water Heaters. [Beitrag zur Frage der Rostungserscheinungen in Warmwasserbereitern (Boilern).] Karl Daeves & Rudolf Grossschupff. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Sept. 4, 1932, pages 465-466.

The causes of such corrosion are first discussed. Statistical research proves that material, stray currents and H_2O analysis (with exception of gas content) are of minor importance. Corrosion in water heaters is primarily caused by the construction. Low pressure heaters installed at the Vereinigte Stahlwerke showed hardly any tendency to corrosion, high pressure boilers were completely destroyed after 3 years of service. The high pressure heaters were fed direct from the municipal water line, whereas an intermediate tank was used on the low pressure heaters which obtained the water preheated. GN (4)

Corrosion and Construction in the Literature. (Korrosion und Konstruktion im Schrifttum.) Walter Deutsch. *Korrosion und Metallschutz,* Vol. 8, Aug. 1932, pages 205-210.

Choice of materials should go hand in hand with correct construction. Proper use of building and structural materials is emphasized by references to relevant articles in the literature. 65 references. BER (4)

The Behavior of Metals against Salts, in particular against Ammonium Salts in the Presence and Absence of Ammonia. (Ueber das Verhalten von Metallen gegenüber Salzen, insbesondere gegenüber Ammonsalzen in Gegenwart und ohne Gegenwart von Ammoniak.) Hildegard Ehrig. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 206, July 1932, pages 385-397.

The metals Cu, Bi, Pb, Ni, Co, Fe, Cd, Zn and Mg were investigated to find the causes leading to a dissolution of the metal after an electrolytic deposition of the metal from an ammoniacal solution and to obtain some insight into the mechanism of corrosion. Cd, Zn and Mn were strongly dissolved, Cu to a lesser degree. The various chemical reactions taking place between metal and solution and the importance of NH_3 is discussed in detail. Ha (4)

Corrosion of Binary Alloys of Magnesium. H. Endo and S. Morioka. *Kinzoku no Kenkyu,* Japan, Aug. 1932, pages 328-366.

Binary alloys of Mg containing 1 to 8 % Sn, Bi, Tl, Cd, Pb, Zn, Sb, Al, Ca and Ni were immersed in distilled water, 1/10 *N* NaCl solution and sea-water and the weight loss of each specimen was measured after an exposure of 30 days. Alloys containing 8 % Al and 5 to 8 % Ni proved to have strong resistivity to corrosion in distilled water. Alloys containing other elements showed weak resistivities. In 1/10 *N* NaCl solution and in sea water, alloys containing Cd, Zn and Sn showed good results irrespective of their contents, and the alloy containing Pb showed best results when its content is 2 to 3 %. Other elements proved to have no marked resistivity. Al and Ni showed no resistivity in this case. The most interesting fact in the above results is that: Cd and Zn which belong to the same group as Mg in the periodic table and have the same space lattice as magnesium showed the best resistivity to corrosion. Ca and Al which have very similar chemical properties but different space lattices showed no good results. Corrosion tests were also carried out by means of salt spray and intermittent immersion tests. The results were almost the same as in the immersion test described above. KT (4)

Surface Protection of Light Metals. (Oberflächenschutz von Leichtmetallen.) J. Feiser. *Die Umschau in Wissenschaft und Technik,* Vol. 36, May 28, 1932, page 428.

After mentioning paint coatings, galvanic coatings, mechanical plating, anodic oxidation is discussed and attention is directed to the Eloxal method of the Vereinigte Aluminium Werke. The bath consists of oxalic and chromic acid. A film of 0.02-0.03 mm. thickness is secured, the properties of which can be varied between a hard brittle oxide, almost as hard as corundum, or a less hard and elastic oxide. Stress is laid on the fact that the Eloxal layer is a perfect insulation. The chemical resistance can be improved by impregnating the film with paint coatings which may be any color. Al-pistons impregnated with fat did not display any noticeable sign of wear. Eloxal films show a greater resistance to wear than Cr plated surfaces. EF (4)

Cathodic Protection of Metals in Neutral Solutions. U. R. Evans. *Metals & Alloys,* Vol. 2, Feb. 1931, pages 62-64.

The author describes experiments on the protective value of cathodic current density and gives the results of a number of measurements. The variation between specimens of the same material was found to be greater than that between different salt solutions. The effectiveness of cracked Zn and Al coating in protecting Fe against various corrosive conditions is discussed. 7 references. WLC (4)

Corrosion When Oxygen is Present and Absent. Reply to E. Liebreich. (Korrosion unter und ohne Mitwirkung von Sauerstoff. Erwiderung an E. Liebreich.) U. R. Evans & C. W. Borgmann. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 160, June 1932, pages 194-204.

Corrosion tests on samples of Fe (0.03 C, 0.021 Mn, 0.017 Si, 0.18 S and 0.006 P) and of steel (0.34 C, 0.64 Mn, 0.2 Si, 0.025 S and 0.027 P) vertically placed in a 0.1 *N* KCl solution, proved that the intensity and distribution of the corrosion attack is entirely different according to whether $N_2 + H_2$, or air + 0_2 are present above the water line. It is shown by means of horizontal samples that the corrosion caused by a drop of 0.1 *N* KCl solution is the same, irrespective of the surrounding air being unsaturated, saturated or over-saturated with water vapor. These observations are not in agreement with the experimental tests of E. Liebreich, on which the latter bases his criticism of the corrosion theory with particular regard to the differential aeration effect. EF (4)

The Formation of Sulphide Layers on Silver and Silver Alloys. (Ueber die Bildung von Sulfidschichten auf Silber und Silberlegierungen.) Kurt Fischbeck. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 593-598.

An optical method was used for following the formation of the sulphide layer on Ag, Cu, Ag-Cu and Ag-Cd alloys, wherein light reflected from the coated metal plate is compared by means of the Pulfrich step photometer with that from a clean plate. The increase of coating thickness with time was found to follow Fick's diffusion law. Cd in small quantities has little effect in slowing down the formation of sulphide on Ag-Cd alloys; above 30% Cd the action of S is very slight. Cu is not affected by the presence of Ag in quantities less than the amount necessary to form the eutectic. The presence of small quantities of Cu in Ag alloys increases the coating formation, indicating that the permeability of a Ag_2S layer containing Cu_2S is greater than that of Ag_2S alone. Ha (4)

The Rusting Process under Differential Aeration. (Über den Rostvorgang bei ungleichmässiger Belüftung.) G. Schikorr. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 160, June 1932, pages 205-210.

Some of Liebreich's observations are seemingly in disagreement with Evans' corrosion theory of differential aeration. Experiments are carried out which proved that the Evans theory is still valid under testing conditions as described by Liebreich. The experimental results are summarized as follows: An Fe surface in a highly polished state is at least barely attacked by normal NaCl solutions when air is excluded. Even if evaporation is prevented and the air admitted, an Fe spot covered by a drop of NaCl solution is particularly heavily corroded in the interior regions of the boundary region Fe/solution. In a short circuited cell pure Fe/2 *N* KCl solution/2 *N* HCl solution/pure Fe. The Fe in the KCl solution, goes preferably into solution, if the total resistance is sufficiently low. The corrosion phenomena observed on Fe under irregular oxygen distribution, are interpreted by the Evans theory to a far-going extent. EF (4)

The Chemical Reactions of the Corrosion of Metals. (Über die chemischen Reaktionen bei der Korrosion der Metalle.) G. Schikorr. *Paper Second Corrosion Congress Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde and Verein deutscher Chemiker,* Oct. 17, 1932, Berlin. Mimeographed report, pages 1-2.

The velocity of corrosion depends essentially on the chemical reactions and the products of corrosion. The actual reactions of corrosion are oxidation and reduction. In particular the process of oxidation in metal corrosion is the transition metal → metal ion. The primary occurrence may also be halogenous ion → halogen. In the corresponding reduction process the electrons set free at oxidation are absorbed by O molecules, H or metal ions which in turn are transformed to hydroxyl ions, gaseous H and metal respectively. Besides these electro-chemical reactions there may still occur in the solution purely chemical reactions which also have a large bearing on the further course of corrosion. Thus, a large number of reactions frequently affect a certain type of corrosion. In determining the velocity of corrosion it is of importance to know which reaction proceeds the slowest, since this one frequently characterizes the whole process. The influence of the products of corrosion on the process was considered at length. The corrosion of metals by gases in the absence of water can be subjected to other laws than while H_2O is present so that conclusions from one type of corrosion to another are to be drawn cautiously. However, it is to be emphasized that also in the presence of H_2O occurrences of considerable variety can be decisive so that conclusions from the behavior of a metal under certain conditions can be drawn on the behavior under other conditions only when the factors of corrosion are comparable in both cases. GN (4)

Solution of Aluminum in Alkaline Solutions. (Die Auflösung von Aluminium in alkalischen Lösungen.) G. Schikorr. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 610-613.

The rate of solution of Al strips was determined by the rate of generation of H_2. There is an induction period, followed by a rise in rate to a maximum, a fall later to zero (for solutions under 0.95 *N*) and a rise to a second, lower, maximum. The inactive period is lengthened by Na_2SiO_3. Similar results were obtained with KOH, $Ba(OH)_2$ and NaOH plus NaCl. The rate of solution was independent of the purity of the Al, the dimensions of the test piece and the H_2 overvoltage. Ha (4)

On the Oxidation of some Gray Cast Iron. U. HASHIMOTO. *Kinzoku no Kenkyu*, Japan, Vol. 9, May 1932, pages 218-224.

Cast irons used for many years unbroken were compared with those damaged in a short time. 3 different cases of the oxidation of ordinary gray cast Fe were microscopically investigated, i.e. (1) 2 cast Fe bars and plates of fire grating oxidized by the coal fire, (2) the cast Fe valve for the exhaust gas of a coal gas producer exposed to gas of 400° C. and (3) the cast Fe cover of a heating box injured by the heating medium. In all cases it was observed that the cast irons with more Si, P and S, with less Mn and with large lamellae of graphite were oxidized to a greater degree than those of opposite compositions. Slag inclusions seemed to be unfavorable to heat resistivity. KT (4)

Progress in Steel Metallurgy as Regards Resistance to Corrosion. W. H. HATFIELD. *Journal West Scotland Iron & Steel Institute*, Vol. 39, Part V, Feb. Session 1931-2, pages 77-92. It is believed that ordinary Fe or steel develops a protective film when exposed to the atmosphere, but that this film is not sufficiently resistant to corrosion. The author is of the opinion that the phenomenon of passivity is not always sufficiently studied by the technologist, and that laws of physical chemistry should be applied in studying corrosion resistance of steels. The first common resistant steel was the 14% Cr, 0.30% C steel used for cutlery. The required hardness of this steel is obtained by hardening from 950°-1000° C. and tempering at 180°-200° C. The next advance in the development of corrosion resistant steel was the 18:8 type. A new type of austenitic Cr-Ni steel, developed especially for use when extreme ductility for pressing work is required, contains 12% Cr and 12% Ni. This steel, after quenching from 1050° C. is considerably softer and more ductile than the 18:8, possessing a considerably reduced cold-work hardening property. The welding and machining properties are also discussed. One point of interest is that intercrystalline corrosion is reduced by lowering the C content to 0.07% or by the addition of 0.7% W especially if the softening temperature was kept at 950° C. Accelerated Tests Reveal Erosion-Resisting Metals. T. F. HENGSTENBERG. *Power*, Vol. 76, Sept. 1932, pages 118-120. Specimens of various metals whirled past a water jet at speeds up to 1200 ft./sec. show test results that agree closely with their actual erosion as machine parts in commercial service. In general, the harder materials offered the greatest resistance to erosion. AHE (4)

Time-potential Curves on Iron and Steel and their Significance. T. P. HOAR & U. R. EVANS. *Iron & Steel Institute, Advance Copy* No. 6, Sept. 1932, 12 pages. A new method for determining time-potential curves is described. A frayed filter paper saturated with electrolyte is in contact with the surface to be tested. The curves obtained give information regarding the behavior of the oxide films. Curves for various steels and various solutions are shown. Curves for Fe and steel show at first rapidly falling potentials in chloride and sulphate solutions. The tendency to break down is greater for rough surfaces than for smooth surfaces. Liquids containing chromate show a tendency to repair the film if enough chromate is present. Alloys containing Cr tested in chloride solutions give rising, level, or falling potentials depending on conditions. 15 references. JLG (4)

Corrosion Prevention by the Atrament Process. (Rostschutz durch Atramentverfahren.) A. KARSTEN. *Korrosion*, supplement to *Chemische Apparatur*, Vol. 19, Jan. 25, 1932, page 1.

The atrament process consists of producing a surface film on Fe by immersion in a solution of phosphate salts of a definite composition. The film is said to be resistant to aqueous and atmospheric corrosion and other types of attacks. The film forms a good base for paints. See also "The Atrament-Process," *Metals & Alloys*, Vol. 2, Dec. 1931, page 299. BER (4)

Surface Protection of Light Metals. (Oberflächenschutz der Leichtmetalle.) TH. LEIB & FR. KOLKE. *Farben Zeitung*, Vol. 36, June 11, 1931, page 1266.

Experience on Low Pressure Turbine Blades in the Klingenberg Power Station. (Erfahrungen mit Niederdruckturbinen-Beschauflung im Kraftwerk Klingenberg.) FR. GROPP & W. ELLRICH. *Elektrizitätswirtschaft*, Vol. 30, Oct. 1931, pages 589-593.

Practical experience on turbine blades was gained in the German Power Plant Kingenberg on the following materials: (1) V5M steel with 14.0 Cr, 0.6 Ni, 0.15 C, 0.7 Si, 0.5 Mn, 0.02 P+S, 84.01 Fe; (2) 5% Ni-steel with 0.14 Cr, 0.31 Si, 0.32 Mn, 0.014 P, 0.002 S, 94.19 Fe; (3) WF100 with 18.6 Ni, 9.64 Cr, 0.57 C, 1.63 Si, 0.82 Mn, 0.01 P, 0.003 S, 68.72 Fe; (4) Monel metal with 67 Ni, 28 Cu, 5 Fe, Si+Mn; (5) Nickel brass containing 50 Cu, 40 Zn, 10 Ni; (6) Mn-steel with 13% Mn. Steels (1) - (3) exhibited erosions beginning at the fourteenth low pressure stage and gradually increasing in depth toward the 24th stage. The observations were made after 10,000-15,000 service hours. The erosions occur immediately after entering the wet steam range and not at a moisture of 6-7% as is generally assumed. In order to prevent these erosion effects, the edge of the 5% Ni-steel blades was provided with lashings. The material used for the reinforcement was Monel metal. The experiment was not successful, since erosions showed up after 844 hours in service. A second test was run, in which Ni-brass (5) reinforcements were employed which however also failed in service. The difficulties were entirely overcome when lashings of 13% Mn steel were applied on V5M steel (1) blades and on some turbine blades of steel WF100 (3). No erosions were noticed after thousands of service hours. The paper includes tables which give the physical properties at ordinary temperatures of the material listed under (1) - (5). Some diagrams show the distribution of the erosion on the turbine blade and a set of curves reveals the state of erosion in relation to the time in operation. It is noteworthy that the initial heavy corrosion gradually decreases after the blades are in operation for say 3000-5000 hours. The maximum critical depth of erosion is computed to be 10 mm. One diagram shows the stress of a turbine blade in the 24th low pressure stage in relation to the erosion. EF (4)

Field Tests of Metallic Coatings. F. A. HULL, *et al. Proceedings American Society for Testing Materials, Preprint* 12, 1931, pages 11-40.

Report of subcommittee 8 of Committee A-5. Extensive tabulated data are given on the progress of corrosion of the galvanized sheet specimens and of the hardware, structural shapes, conduits, etc., which were provided with a variety of protective coatings and exposed in various locations. Ha (4)

Use of Arc-Welded Alloys to Arrest Corrosion of Ordinary Small Refinery Equipment. RAYMOND S. HOFFMAN. *Oil & Gas Journal*, Vol. 31, Sept. 1, 1932, page 10.

A method is illustrated of protecting against corrosion the C steel fittings of pipe-line joints in cracking equipment. A protective covering of non-corrodible alloy, for instance KA2 or NCT 3, is welded on by arc welding. A flux-coated electrode of the alloy is employed with 20-22 volts across the arc and current of 150 amperes from portable d.c. generators. A saving of $21,871 was effected by the use of arc-welded alloy-lined fittings for a high-pressure cracking plant. (4)

Corrosion on Fire Fighting Vessels and Its Prevention. (Korrosionserscheinungen an Feuerwehrfahrzeugen und die Massnahmen zu deren Bekämpfung.) F. REINCKE. *Korrosion und Metallschutz*, Vol. 8, July 1932, pages 169-172; *Farben Zeitung*, Vol. 37, May 14, 1932, pages 1058-1059.

Paper before the Verein Deutscher Ingenieure and Verein Deutscher Chemiker, Berlin, Dec. 1931, refers to failure in service after 6 months due to corrosion of steel boiler tubes in fire fighting engines. Investigations showed that the source of trouble was neither defective material nor the composition of the boiler water. The presence of electrochemical influences was soon proved by Zn-linings which were rapidly dissolved but checked the corrosion effect. New fire fighting vessels also exhibited severe corrosion after relatively short service periods. A coating of black varnish after the removal of rust was not effective. Water analyses taken at the fire fighting station did not yield any clue. The presence of electrolytic currents between the bronze screw and the Fe ship hull was counteracted by a metallic Zn spray coating on the sand blasted hull. The most endangered parts were furthermore provided with 5 mm. Zn plates. The latter disintegrated after half a year and were replaced. Corrosion still occurred. Then the electric lead wires were freshly insulated and the single terminals were removed, the corroded parts were repaired by welding, the bronze propeller was replaced by a steel screw and 6 mm. Zn plates were welded on the hull. This finally checked the corrosion attack which was greatest at parts exposed to the most intensive currents and was promoted by the combined action of air and water. Zn plates should not be screwed or riveted on but welded. The ground coat must be applied immediately after cleaning and drying of the surface, i.e. before Fe oxide hydrate develops. EF (4)

Effect of pH on the Corrosion Products and Corrosion Rate of Zinc in Oxygenated Aqueous Solutions. B. E. ROETHELI, G. L. COX & W. B. LITTREAL. *Metals & Alloys*, Vol. 3, Mar. 1932, pages 73-76.

The authors discuss the action of the products of corrosion in protecting the body of metal from further corrosion. The possibility of destruction of the film by solutions of varying pH is discussed. The amphoteric character of Zn hydroxide suggested that a study of the corrosion of Zn in aerated salt solutions of varying pH might show results of interest. The apparatus for conducting such experiments is described. The curve of corrosion rate vs. pH shows a very low rate of corrosion between pH of 6 and 12.5. This is attributed to the formation of dense adherent corrosion product films. The high corrosion above and below these values of pH is attributed to high solubility of corrosion products and ease with which H and hydroxyl ions and O reach the metal surface. Variations in the turbulence of the solution and other external factors may affect the limits of the formation of a stable film or may result in pH gradients from points immediately adjacent to the specimen and the main body of the solution. 41 references. Note on article "Corrosion Resistance of Cu, Sn-bronzes and Sn towards Inorganic Acids. (Zuschrift/Zur Kenntnis der Widerstandsfähigkeit von Kupfer, Zinnbronzen und Zinn gegen anorganische Säuren.) W. ROHN. *Zeitschrift für Metallkunde*, Vol. 24, July 1932, page 153.

It is claimed that the classification used by Claus and Finke in their article on the above subject is not to be recommended. RFM (4)

Corrosion Stability — Including Galvanic Influences — of Metallic Structural Material in Brewery Industry. (Die Korrosionsbeständigkeit—einschliesslich galvanischer Einwirkungen—der metallischen Werkstoffe in der Brauindustrie.) P. SCHAFMEISTER & W. TOFAUTE. *Zeitschrift für das gesamte Brauwesen*, Vol. 55, Jan. 1932, pages 1-7; Jan. 1932, pages 9-11.

Comparative laboratory tests including Al, Cu, Fe, tin plated Fe and V2A steel showed that V2A is by far most superior in regard to losses in weight and in galvanic corrosion in both water and beer. Intercrystalline corrosion in welded joints is overcome by the application of special alloys V2A-H and V2A Extra. EF (4)

Wear of Wrought Iron vs. Steel Pipe. STANLEY P. WATKINS. *Metals & Alloys*, Vol. 2, Feb. 1931, pages 51, 56.

The author reports the superior resistance of wrought Fe over steel in the discharge pipe of river dredge where the discharge consists of 70% sand and 30% gravel. WLC (4)

The Cause of Corrosion of Automobile Parts by Lubricants. (Die Ursache der Korrosion von Kraftfahrzeugteilen durch Schmiermittel.) WAWRZINIOK. *Automobiltechnische Zeitschrift*, Vol. 35, Sept. 10, 1932, pages 428-430.

Tests have shown that in spite of the very low acid content (less than permissible) of lubricants some oils can form local elements and act as electrolytes so that strongly corrosive effects take place. This can often be enhanced by defects in the electric installation of a vehicle on account of stray currents. Oils should be as free of acid as possible and have a high electric resistance. Ha (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Structural Metallography. H. B. Pulsifer. *Metals & Alloys,* Vol. 2, Feb. 1931, pages 84-88. The author discusses methods of surface preparation and etching. The use of various reagents for etching is discussed and illustrated by a number of micrographs. The author shows evidence of a finer structure within the usual grain structure of metals which can be developed with more active reagents. The relation of this structure to cold working characteristics is cited as a fertile field for study. The shape of grains, most frequently square or hexagonal, is discussed in the light of surface tension and close packing of the grains. WLC (5a)

The Dia- and Paramagnetism in Series of Metallic Solid Solutions. (Zum dia- und Paramagnetismus in metallischen Mischkristallreihen.) Eckhart Vogt. *Annalen der Physik,* Series 5, Vol. 14, July 1932, pages 1-39. The general character of the metallic state is expressed by the uniform electric behavior of different substances, while the special characteristics of the lattice structure determine the magnetic behavior. The latter was exhaustively investigated in several series of solid solutions of alloys of Au-Ag, Au-Pd and Pt-Pd at high and low temperatures. The magnetic behavior of alloys can be represented by a quantity called "atomic susceptibility" which is brought in relation with the rule of mixtures and the deviations from which are determined for the various solid solutions. Ha (5a)

The Equilibrium Conditions in the System Fe-C-O. (Ueber die Gleichgewichte im System Fe-C-O.) Ernst Jaenicke. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 204, Feb. 24, 1932, pages 257-290. Taking into account all recent investigations on this subject the author modifies and revises his previously developed equilibrium diagram in such a manner that it becomes quantitatively correct as well as diagrammatically. The equilibria at different temperatures and pressures are calculated and graphically represented in a diagram which permits a distinction between the metastable and stable equilibria. Formulas for the relation of pressure and temperature are developed and the heat of formation of cementite is calculated. Contrary to current views, it is shown that a pressure maximum exists in the stable range at about 820° C. for the equilibrium of the 3 solid phases Fe, austenite, and FeO. A 3 dimensional diagram shows clearly the relations of composition of the gas, temperature and pressure to the constituent substances. 20 references. Ha (5a)

A Further Contribution on the Constitution of the Fe-C-Si System. A. Kříž & F. Poboril. *Iron & Steel Institute, Advance Copy* No. 7, Sept. 1932, 27 pages. Alloys containing a variable C content and 10 and 16% Si were studied by thermal and microscopic methods. Using the results of this study and data previously reported on alloys of lower Si content, constant-Si sections of the ternary diagram were constructed. Without an unwarranted amount of extrapolation, both the metastable and stable diagrams for the corner containing up to 16% Si and 4.5% C were constructed. A carbide, probably Fe_3C dissolving Si, occurs in the former system, which is replaced by graphite in the stable system. Projections of monovariant lines on the composition plane and isothermal sections are developed. A 4-phase plane at 1155° C. in the metastable system has the corners: α at 10.2% Si and 0.26% C, γ at 8.2% Si and 0.54% C, liquid at 6.9% Si and 2.61% C, and carbide at an undetermined composition. In the stable system the corresponding plane is at 1165° C. and has the corners: α' at 9.7% Si and 0.22% C, γ' at 7.7% Si and 0.52% C, liquid at 6.4% Si and 2.54% C, and graphite at 100% C. These planes are quadrangles and therefore do not represent eutectic reactions. 4 references. JLG (5a)

The Applicability of the Ideal Mass Action Law to Metallurgical Processes. (Anwendbarkeit des Idealen Massenwirkungsgesetzes auf metallurgischen Prozesse.) F. Körber. *Die Naturwissenschaften,* Vol. 20, May 27, 1932, pages 409-412. The ideal mass reaction law, the Nernst Distribution Law (*Zeitschrift für anorganische und allgemeine Chemie,* Vol. 145, 1925, page 240) and the general mass reaction law according to Lorenz and van Laar are anticipated. The latter contribution to physico-chemistry had been checked on heterogeneous Pb-Sn melts under chloride slags between 500° and 600° C. The theoretical equilibrium isotherm of the Mn-reaction between steel and slag is not in accordance with the actual observations of practical steel making. Recent tests in the Kaiser Wilhelm Institut für Eisenforschung on the relationship between Mn-bearing Fe and slags consisting of MnO + FeO showed that the ideal mass reaction law can be considered as the fundamental equilibrium relationship. The concentration of Mn in the melt varied between 0 and 4% while MnO in the slag phase increased to above 70%. The temperature dependence of the equilibrium has been confirmed and corresponds to the reaction heats computed from formation heat of the oxides. Based on experimental observations, the writer ascribes the divergencies of Lorenz' data from the ideal mass reaction law to the fact that equilibrium conditions are attained in a surprisingly short time, so that only exceedingly rapid quenching preserves the equilibrium at a certain testing temperature. Owing to this, the experiments of Lorenz on the system Pb-Sn-$PbCl_2$-$SnCl_2$ were re-examined with the precautions mentioned above. The experiments proved that the reactions follow the true mass reaction law between 500° and 800° C. No indication of a break at the side of the nobler metal was noticed. Furthermore the equilibrium $Cd + PbCl_2 \rightleftarrows CdCl_2 + Pb$ was redetermined and found to follow the ideal isotherm to a more pronounced degree as previously determined by Lorenz and co-workers. The author concludes that in studying the steel making processes on thermo-dynamic grounds, the general mass reaction law offers a reliable guidance through the great variety of metallurgical reactions. However the difficulties involved in introducing the correct molar concentration into the calculation are not eliminated. EF (5a)

The Copper-rich Alloys of the Copper-nickel-tin system. John T. Eash & Clair Upthegrove. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 29 pages. Some questionable parts of the Cu-Sn system were studied, and a corrected diagram drawn. Cu-rich alloys of the Cu-Sn-Ni system containing 2, 3, 5, 10 and 20% Ni were studied by thermal, X-ray and microscopic methods. The Cu corner of the ternary diagram was constructed. The addition of Ni to Cu-Sn alloys causes the α field to contract, the contraction being greater at room temperature than at higher temperatures. The α plus γ field likewise diminishes as the temperature is lowered. 29 references. JLG (5a)

The Intermediate Phases of the Iron-tungsten System. W. P. Sykes & Kent R. Van Horn. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 15 pages. Metallographic and X-ray studies proved that a phase corresponding to the formula Fe_2W was formed by reaction between the Fe-rich solid solution and Fe_3W_2 at 1040° C. This phase had been previously detected by Arnfelt, but had not been found by later workers. The eutectic was found to occur at 49% W. No evidence for the X-phase presumed by Takeda was found. 8 references. JLG (5a)

The Structure of White Bearing Metals. (Das Gefüge der weissen Lagermetalle.) Thews. *Die Metallbörse,* Vol. 22, May 14, 1932, page 610. The contradictory properties expected of bearing metals are secured by hard crystals embedded in a soft matrix or by a hard matrix containing a soft net-like structure. The segregation tendency of the hard Sb-Sn crystals in Sn rich white bearing metals is counteracted by an addition of Cu. The lower the casting temperature and the faster the cooling, the smaller and more numerous the hard constituents. The bearing properties are reduced by the area decrease of the hard crystals. If the latter are in touch with each other, the plasticity and tenacity of the bearing is decidedly impaired. With regard to the Pb-bearing metals, the compressive strength increases with rising Sb contents up to the eutectic composition (87% Pb, 13% Sb). Further increase of the Sb content induces brittleness. In Pb-Sb-Sn alloys, Sn reduces the hardness and compressive strength of the matrix. In the soft Pb-Cu-Sb alloys, the hard constituent consists of violet, needle-shaped Sb-Cu crystals; the balance of Sb + Cu goes into the matrix and improves its physical properties. An analogous structure prevails in special Pb bearing metals which comprise alkali and earth alkaline metals. The hard primary Pb_3Cu and Pb_3Ba crystals are embedded in a soft eutectic matrix which also contains Ca, Ba, etc., in solid solution. EF (5a)

A Study of Segregate Structures in Copper-tin and Silver-zinc Alloys. D. W. Smith. *American Institute Mining & Metallurgical Engineers, Preprint,* Oct. 1932, 14 pages. The form and orientation of the α precipitate in the β matrix of Cu-Sn and Ag-Zn alloys were studied by microscopic and X-ray methods. The α phase in segregating from the β phase in Cu-Sn alloys takes the form of needles parallel to a [111] direction in the β phase. From observations of the twinning planes of the α segregate, the α phase was found to be orientated with respect to the β phase so that a (111) plane in the α phase was parallel to a (110) phase of the β matrix. The direction of the α needles in Ag-Zn alloys was the same as in the Cu-Sn alloys. The orientation of the α lattice could not be determined. The significance of the results are discussed, and analogies pointed out. 8 references. JLG (5a)

Protection of Microspecimens. Correspondence from Enrique Touceda. *Metals & Alloys,* Vol. 2, Feb. 1931, page 51. The writer suggests the use of cellophane tubes used for cigar wrapper as effective and convenient means of protecting the surface of specimens prepared for microexamination. WLC (5a)

The Alloys of Iron, Vanadium and Carbon. *Metallurgist,* June 1931, pages 91-94; July 1931, pages 98-100. An extended abstract of the work of R. Vogel & E. Martin and of H. Hougardy, *Archiv für Eisenhüttenwesen,* Vol. 4, Apr. 1931, pages 487-495 and 497-503. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 301 and Vol. 3, Feb. 1932, page MA 34. VVK (5a)

Recent Developments in the Study of the Constitution of Alloys (Die neuere Entwicklung der Konstitutionsforschung der Legierungen). W. Guertler. *International Association for Testing Materials, Zurich Meeting, 1931,* Vol. 1, 1932, pages 469-483. References to, and brief statements of the new features of, recent work on binary alloys of Fe with Ni, Co, Mn, Si, Cu, Zn, C, W, Mo, Cr, V, N, P, B, Bi, As, Sb; of Cu with Zn, Sn, Si, Mg, Be, Pb, Mn, Au, Ag, Pd, Pt; of Co with Ni, Cr, Cu; of Cr with Ni, N; of W with C, Re; of Mo with C; of Pb with Zn, Sn, Sb; of Sb with Zn, Tl; of Cd with Zn, Hg; of Al with Cu, Fe, Si, Mg, Be, Mn; of Mg with Zn, Cd; of Be with Ni, Si, Co, Fe; of Ag with Pt, Zn, Cd, Al; of Au with Pt, Ni, Zn and Cd. Progress of Metallography. J. L. Haughton. *International Association for Testing Materials, Zurich Meeting, 1931,* Vol. 1, 1932, pages 457-468. Methods of determining equilibrium diagrams are described in general terms, with a few details on dilatometric methods. 21 references. HWG (5a)

Photomicrography. A. MacDougall. *Journal West of Scotland Iron & Steel Institute,* Vol. 39, Part II, Session 1931-32, Nov. 1931, pages 13-28; *Heat Treating and Forging,* Vol. 18, June 1932, pages 357-359, 366. It is pointed out that it is exceptionally difficult to truly represent the structure of a metal in a permanent form. Careful manipulation helps greatly in the production of a record which may be as near as possible a true representation of the structure. The technique of photomicrography is discussed and illustrated with high magnification. It was found that illumination by a plane glass is in the order of 22-23% of the total light. In the case of the prism the illumination is about 78%, and therefore the exposure could be decreased. MS + GTM (5a)

Austenite-pearlite Transformation and the Transition Constituents. Albert Sauveur. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 247-254. Includes discussion. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 161. (5a)

The Influence of the Life Story of the Alloys on their Properties. (L'Influence de l'Histoire de la Vie des Alliages sur leurs Qualites.) A. Mitinski. *Revue Universelle des Mines,* Series 8, Vol. 8, Sept. 15, 1932, pages 181-182.

A general discussion of the equilibrium diagram of cast Fe; it is pointed out what influence space and time of fusing in the blast furnace exert and how the eutectic points are changed by the addition of other ingredients besides Fe and C. The change of quality of a cast Fe by addition of several components is not the sum of the qualities of the individual components. Ha (5a)

Metallographic Investigation of Chromium-Molybdenum Steel During Different Stages of its Manufacture. K. F. Starodubov & F. M. Gorbacheva. *Domez,* No. 3, 1932, pages 44-46; No. 4-5, 1932, pages 47-54. (In Russian.) Detailed description is given of the furnace practice and the properties of ingots made of open hearth Cr-Mo steel cast in straight wall big end down ingot molds. Macroetching, microexamination and physical testing were used. Nothing unusual was found. (5a)

The System Calcium Oxide-Phosphorus Pentoxide. (Beiträge zur Kenntnis des Systems Kalziumoxyd-Phosphorpentoxyd.) Gerhard Trömel, with microscopic investigations by Hans Schneiderhöhn. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 14, No. 3, Report 198, 1932, pages 25-36. From a review of the literature it is observed that many difficulties generally arise in attempts to study the equilibrium of this system. Factors which are deterrents are the strong reactivity of Ca_3PO_4 and the high reaction temperatures produced. The method used for making the melts must be such that the composition of the mixture, during fusion, does not vary due to absorption of impurities from the crucible, and also that it must be possible to hold the temperature above the fusion point for such a period as is necessary for the mixture to combine uniformly. The use of Pt for the crucible, the resistance winding, and thermocouples is satisfactory up to 1600° C. Ir, due to its high cost and volatility would be unsuitable. In the CaO-rich part of the system the temperatures run above 1600° C. The use of ceramic materials for crucibles is impossible due to attack by lime phosphates. Even highly fired crucibles of MgO, ZnO, etc., are rapidly attacked by the melt. P_2O_5 vaporization is another factor. Rh serves well up to 1984° C and its sp.g. of 12.1 against 21.4 for Pt means that much less white metal is needed for the same size crucible. Rh is slightly oxidized by heating in the atmosphere, the formation of its oxide is shown by partial discoloration of the melts. The reaction is not as vigorous as with silicates. 30 references. Recrystallization of Aluminum and Some Age-hardening Aluminum Alloys. (Über die Rekristallisation von Aluminium und einigen vergütbaren Aluminiumlegierungen.) R. Vogel. *Die Metallbörse,* Vol. 22, Apr. 2, 1932, pages 418-419. Tests were made with (1) pure Al of 99.67 Al, 0.13 Si, 0.2 Fe; (2) Al alloy L containing 4.22 Cu, 1.89 Si and 0.41 Fe; (3) Al alloy A with 4.4 Cu, and 0.47 Mn; (4) alloy B with 6.5 Cu and 0.67 Mn. The samples were submitted to plastic deformation at elevated temperatures. In all specimens a peak value was found, i.e. the crystallites start with a maximum grain size at a certain degree of deformation. In order to secure the best physical properties, the alloys were treated at temperatures slightly below the eutectic. The recrystallization temperature and the recrystallization power depend on the alloying elements. Mn greatly reduces the recrystallization power. A marked influence of the deformation speed on the grain size was noticed and the recrystallization velocities were found to be surprisingly large. Differences in the behavior of wrought and cast material were noticed. Lower degrees of deformation result in coarser grain. The cast material exhibits a fine grained structure and the grain boundaries are preserved even at far-going deformations. The Tammann hypothesis on the grain boundary substance is stressed as an interpretation. The grain boundary substance is destroyed to a more pronounced degree by rolling than by compressive strength. Thus rolling results in a smaller grain size. The critical deformation range was found between 5 and 20%. Forging must be carried out at high temperatures. Many light blows cause a coarse grain, if the degrees of deformation are equal. The recrystallization temperature of pure Al is lowered by alloying elements. EF (5a)

The Behavior of Single Crystals of Bismuth Subjected to Alternating Torsional Stresses. H. J. Gough & H. L. Cox. *Journal Institute of Metals,* Vol. 48, 1932, pages 227-254. Includes discussion. See *Metals & Alloys,* Vol. 3, Nov. 1932, page MA 320. (5a)

LEITZ MICRO-METALLOGRAPH

Simplified Model "MM-2"

Note: The Leitz Darkfield Equipment and the new series of Leitz Objectives (corrected for infinity) are supplied with the Simplified Micro-Metallograph "MM-2."

The Inverted Microscope and Camera of Micro-Metallograph Simplified Model "MM-2" represent a modified as well as simplified construction of the well known Leitz Micro-Metallograph Large Model "MM-1" which is so successfully used for micro-analysis of metals. The purpose of offering the Simplified Model "MM-2" is *to provide at the lowest possible cost an instrument including all essential equipment both in optical and mechanical respects that meets the entire range of practical requirements from carbon-iron alloys to metals of every variety.*

The New Instrument fulfills a demand which has hitherto existed for micro-metallographic equipment arranged in its construction to meet the efficiency known to exist with the large Micro-Metallograph, however, in price so arranged, that industrial and educational laboratories with a moderate purchasing budget can be accommodated.

Cementite Crystal Structure. P. R. Kosting. *Metals & Alloys,* Vol. 2, Feb. 1931, page 56. Writer comments upon the finding of S. B. Hendricks, *Zeitschrift für Kristallographie,* Vol. 74, 1930, page 534, regarding the structure of cementite giving the measurement data obtained. WLC (5b)

Laue Patterns with Large Deflection Angles. (Laue-Diagramme mit grossen Ablenkungswinkeln.) W. Boas & E. Schmid. *Metallwirtschaft,* Vol. 10, Dec. 4, 1931, pages 917-919. A brief description is given of the preparation of Laue patterns using angles larger than 45° between the zone axis and incident X-ray beam, which is larger than usual. The advantages include the easy determination of the number of points of a diagram even without exact orientation of the crystal, distinct and immediate location of the zones of the plane perpendicular to the X-ray beam, possibility of examining either thick, strongly absorbing crystal samples or thin surface layers, and the possibility of obtaining Laue patterns with low tube voltages. CEM (5b)

Determination of the Solubility of Cadmium in Zinc by X-rays. (Röntgenographische Bestimmung der Löslichkeit von Kadmium in Zink.) W. Boas. *Metallwirtschaft,* Vol. 11, Nov. 4, 1932, pages 603-604. The difference in results of previous investigators was due to impurities in the metals. For these tests c.p. Zn and Cd were used. The cast bars were rolled and drawn to 3 mm. dia. and homogenized at 350° or 250° C. for several days. By means of precision X-ray measurements the lattice constants were determined. The only lines which could be accurately determined were of the planes $(20\bar{2}4)$ and $(12\bar{3}1)$. The constants increase in proportion to the percentage of Cd up to 1.07 atomic % Cd, which is the eutectic, and then remain constant. For pure Zn at 20° C. $a = 2.6584$ A. U., $c = 4.9353$ A. U.; for Zn with 1.07% Cd $a = 2.6622$ A. U. and $c = 4.9456$ A. U. For the determination of the solubility curve samples containing 4.8% Cd were homogenized at 218°, 156° and 100° C. respectively and then quenched. The lattice constants were determined and the % Cd remaining in solution calculated. The solubility curve checks fairly well with that of Jenkins and Stockdale, rising from 0 at 100° to 2.1% at 266° C. 12 references. CEM (5b)

Lattice Spacings of Iron-Aluminum Alloys. A. J. Bradley & A. H. Jay. *Iron & Coal Trades Review,* Vol. 124, May 6, 1932, page 757; *Foundry Trade Journal,* Vol. 46, May 19, 1932, page 308. X-ray Testing of Compressed Gas Cylinders. (Röntgenprüfung an Druckgasflaschen.) *Die Umschau in Wissenschaft und Technik,* Vol. 36, Mar. 5, 1932, pages 192-193. Reports on a general inspection of all compressed gas containers belonging to the Deutsche Reichsbahngesellschaft. EF (5b)

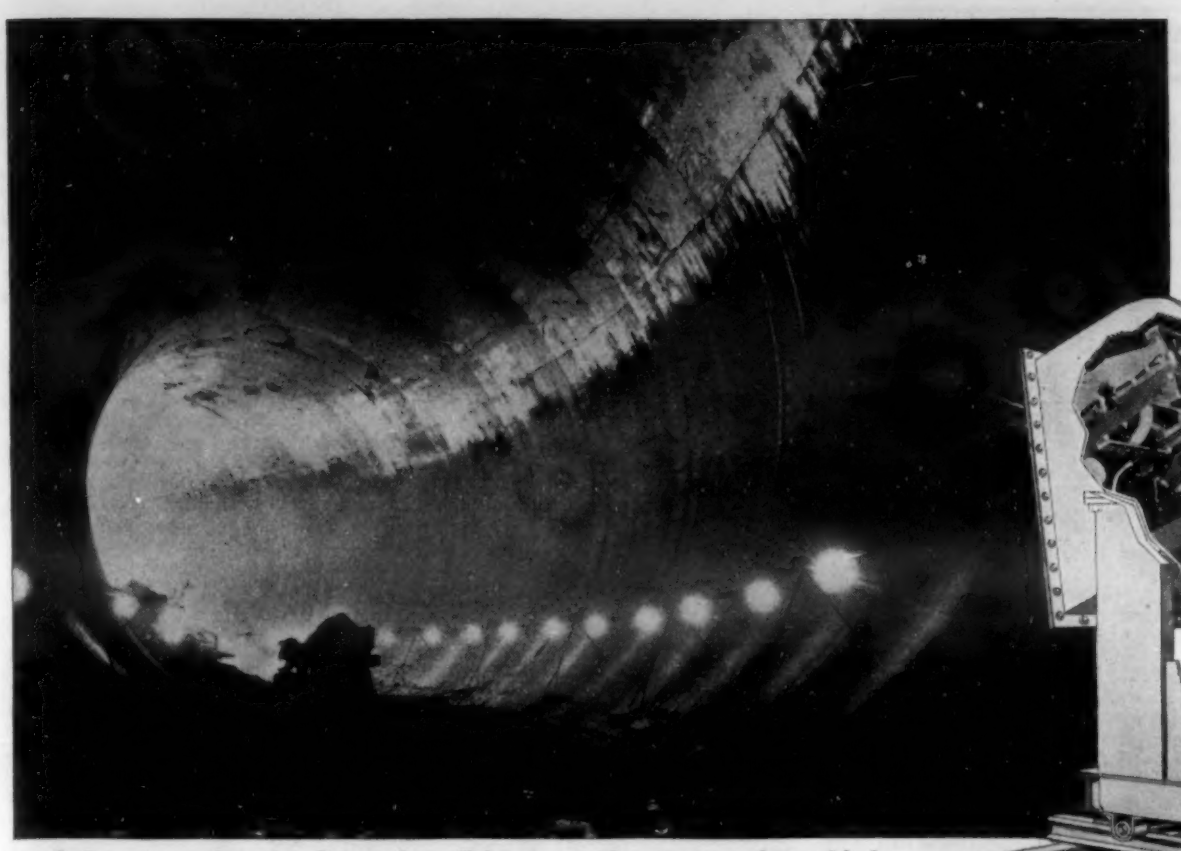
Detection of Faulty Welds. *Electrical Review,* Vol. 110, April 15, 1932, page 557. Describes "Metalix" portable X-ray unit manufactured by Philips Lamps, Ltd., and installed in the Renfrew, Scotland, plant of Babcock & Wilcox, Ltd. Consists of an X-ray tube of heavy loaded capacity, a high-voltage generator, and necessary stands, controls, etc. It is of shock-proof construction and affords complete protection against unwanted radiation. MS (5b)



Investigation of the Binary Solid Solutions of Magnesium. (Untersuchungen an binären Mischkristallen des Magnesiums.) E. Schmid & H. Seliger. *Metallwirtschaft,* Vol. 11, July 22, 1932, pages 409-411; July 29, 1932, pages 421-424. Alloys of Mg containing up to 15.25% Al and up to 15% Zn were prepared in wire or bar form. The lower alloys were annealed in boiling S, the higher alloys in a salt bath at the eutectic temperature, for 24 to 100 hours. Precision X-ray photograms of the alloys were taken and the lattice plane distances were calculated from the Debye-Scherrer rings. In both alloys the distances increase with increasing alloy content until the solubility corresponding to the eutectic temperature is reached, after which they remain constant. These points correspond to 12.1% Al and 8.47% Zn. From the lattice plane distances the lattice constants are calculated. By heating the alloys to various temperatures up to 440° C. and quenching in water and making X-ray examinations the solubility curves Al and Zn in Mg were determined. These curves differ somewhat from those determined metallographically, but are considered more accurate, as the precipitation of minute particles can be detected, which cannot be seen under the microscope. Single crystals of Mg alloys with Al up to 8.78 atomic % and Zn up to 1.92 atomic % were prepared from pressed wires by careful repeated annealing and cold working. Examination showed that the orientation of the crystals varied from 10° to 70° between the base and wire axis. These wire samples were used for tensile tests and the stress-strain diagrams for some of them are given, showing a wide variation in the deformation for various crystal angles. The maximum tensile strength is obtained with 4.5% Al and with 1.6% Zn and is 100% higher than for pure Mg in case of the Al alloy and 30% higher in case of the Zn alloy. The maximum energy required for deformation corresponds to the same alloy concentrations. 5 references. CEM (5b)

The Transformation of Austenite into Martensite in Iron-Nickel Alloys under Load. (Ueber die Umwandlung des Austenits in Martensit in Eisen-Nickellegierungen unter Belastung.) Erich Scheil. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 207, July 1932, pages 21-40. The transformation of the face-centered lattice of the γ Fe solid solution austenite into the tetragonal space-centered α Fe solution martensite cannot be explained by a thermal exchange of places of the atoms but must be considered as a special deformation mechanism. How this is influenced by stresses has been investigated on irreversible Ni steels. Tensile stresses increase the temperature at which the transformation begins and also the amount of the martensite formed. Plastic deformations of the steel cause martensite to be formed only in a certain range above the transformation temperature. The formation of sliding planes secure austenite against transformation into martensite after a certain short time, but only in the direction of deformation. The formation of martensite effects immediately a strengthening of the austenite against formation of martensite and sliding planes. The spontaneous formation of martensite is explained by the existence of inner stresses or better by a mechanical instability of the austenite. 25 references. Ha (5b)

The theory for finding the number of spheres in a sample and the distribution of the sizes of their radii is derived. Ha (5b)

Lattice Distortion of Cold Drawn Constantan Wire. W. A. Wood. *Chemical News,* Vol. 143, Dec. 4, 1931, page 368. Abstract of a paper presented at the Nov. 1931 meeting of the British Physical Society. The space lattice is found to undergo a large distortion as a result of cold working. Description of a method for determining quantitatively the variation in distortion of cold drawn constantan wire and the changes in electrical resistance and temperature coefficient with the distortion. Atomic Structure of KBi_2. Fifth Communication on Metals and Alloys. (Gitterstruktur von KBi_2. 5 Mitteilung über Metalle und Legierungen.) E. Zintl & A. Harder. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 16, Mar. 1932, pages 206-212. Powder photographs of KBi_2 were taken which revealed a cubic structure with the unit cell edge $a = 9.501 \pm 0.005$ A. U. Based on the density $D = 6.908$, 8 K and 16 Bi atoms are calculated for the elementary body. KBi_2 and $MgCu_2$ have identical structure, and the ratio of the diameters of the components are almost the same. EF (5b)

● *Over 75 miles of radiographs will be required to inspect the welded seams of the Hoover Dam penstocks, which measure up to 30 feet in diameter, with a plate thickness of 7/8 to 2 7/8 inches.*

● *This 300,000 volt oil-immersed, shock-proof G-E x-ray apparatus will handle the largest radiographic assignment in x-ray history—the examination of fusion welds in the Hoover Dam penstocks.*

Radiographs by the Mile on Hoover Dam Penstocks

WHEN the waters of the Colorado River enter the penstocks of Hoover Dam, Uncle Sam need have no misgivings regarding their confinement, for every inch of fusion welded seam in these gigantic tubes will have been checked through and through, and pronounced O. K., by General Electric X-Ray Apparatus.

When Babcock & Wilcox were awarded the penstock contract for this colossal project, they faced many unique engineering problems. Not the least of these was the provision calling for radiographic inspection of all fusion welds, totaling more than 75 miles in length.

The immensity of this task was without precedent —never before had such a thing been attempted.

Here, for example, were some of the requirements:

Longitudinal and circumferential welds up to 3 inches thick, in penstock sections ranging from 8½ to 30 feet in diameter, must be radiographically inspected.

To accomplish this radiography of over 75 miles of seam, more than 159,000 separate x-ray exposures must be made, involving the use of more than 24,000,000 square inches of x-ray film.

X-ray facilities must be such that exposures can be made conveniently, rapidly, accurately, safely and consistently, without delaying predetermined schedules in the fabrication of the penstocks.

Based on their experience with G-E x-ray equipment in their Barberton plant, Babcock & Wilcox turned to the General Electric X-Ray Corporation for apparatus which would fulfill these stipulations. As a result, they have been equipped with the 300,000 volt oil-immersed x-ray unit shown here.

This equipment, the most powerful shock-proof industrial x-ray apparatus in use at the present time, has its complete high tension system—transformers, condensers, Kenotrons and x-ray tube—completely immersed in oil and sealed within a compact tank or "head." This head will be so mounted that the x-rays can be quickly directed at any angle required. There is no possibility of accidental high tension shock, as the only external wiring is at low tension, connecting the head, control stand, and power source.

The installation of this x-ray equipment at Hoover Dam marks another epoch in industrial radiography. More and more, specifications are calling for x-ray inspection. Is your plant prepared to meet them? Is lucrative business slipping through your fingers for lack of proper equipment?

Write today for our profusely illustrated descriptive brochure "Industrial Application of the X-Ray" —others have found it profitable reading. Address Industrial Department.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Strength Tests on Thin Walled Duralumin Cylinders. E. E. LUNDQUIST. *National Advisory Committee for Aeronautics, Technical Note* No. 427, Aug. 1932, 8 pages. The report covers the first series of tests on thin walled cylinders and is part of a broad program for obtaining fundamental design data for structures which fail within the elastic range of the material. Test specimens were duralumin cylinders with radii ranging from 7.5″ to 15″ and lengths from 2¼″ to 45″, manufactured from sheet ranging from 0.0105″ to 0.0228″ in thickness. Test data are recorded in the form of curves indicating the effect of variations in the ratio of radius of cylinder to thickness of sheet on the number of shear wrinkles, the angle between the wrinkles and the shearing stress at failure. An equation for shearing stress at failure is derived from empirical results. JBJ (6)

Methods of Testing Cast Iron. (Beitrag zu der Frage der Prüfungsverfahren für Gusseisen.) E. DÜBI. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 75-108, appendix pages 109-112. Recounts extensive tests of 35 cast irons under the auspices of the Swiss Association for Technical Material Testing, comparing specimens from castings of various wall thickness with separately cast specimens. The separately cast specimens are considered satisfactory for evaluation of the material. Chemical analysis, wall thickness and the hardness characteristics serve to define its properties. HWG (6)

Experimental Investigations on the Relation of Tensile Stresses to Velocity of Deformation. (Experimentelle Untersuchungen über die Abhängigkeit der Zugspannungen von der Verformungsgeschwindigkeit.) H. BEUTLER. *Physikalische Zeitschrift,* Vol. 33, Mar. 15, 1932, pages 247-259. Previous results on combined dynamic and static tests which aimed at a correlation of deformation resistance to deformation velocity are summarized. The next chapter deals at length with Prandtl's theory on the time effect during deformation. The author aims at checking Prandtl's theoretical derivations. Some auxiliary apparatus is incorporated in an Amsler-Laffon Testing Machine and a Losenhausen impact machine. The supplementary equipment and its calibration is fully described and illustrated. The experiments refer to 13 mm. rods of Krupp mild steel with 0.20% C, 0.3% Si and 0.6% Mn and to a commercial brand of Cu. The results with Fe showed too great irregularities to draw convincing conclusions. After extending the velocity range, the tests on Cu yielded a close agreement with Prandtl's equation. The constants of this equation are computed to amount to 175 ± 10 kg./cm.² with reference to Fe in the range of flow and to 85 ± 5 kg./cm.² in the vicinity of the tensile strength. The constant for Cu with reference to the tensile strength yielded 28 ± 2 kg./cm.². Previous tests of Cassebaum on 0.46% C, 0.33% Si, 0.7% Mn, 0.038% P, 0.026% S steel yielded a constant of 50 kg./cm.² in the neighborhood of the tensile strength. Improvements on the testing machine permitted the simultaneous record of the factors: time, elongation and stress. EF (6)

On a Correlation of the Virginal to the Remanent State of Magnetization (Über einen Zusammenhang zwischen jungfräulichem und remanenten Magnetisierungszustand.) H. KÜHLEWEIN. *Physikalische Zeitschrift,* Vol. 33, Mar. 15, 1932, pages 348-351. The ballistic evaluation of hysteresis loops of numerous ferro-magnetic alloys yielded the following rule: the virginal magnetization curve represents the arithmetic medium of the slopes of both remanences after a preceding saturation. The experiments refer to permalloy, perminvar and hexagonal Co-alloys. EF (6)

Constant Work of Fracture as Explanation for the Fracture in Fatigue and Other Loading. (Konstante Brucharbeit als Erklärung für den Bruch durch Ermüdungs-und andere Belastungen.) K. LJUNBERG. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 337-339. In tensile testing the total work of fracture is roughly the same whether the loading is applied steadily or is interrupted after strain hardening begins. But if the material is annealed after strain hardening, the total energy of the 2 loadings is greater. HWG (6)

Cable Testing Machine at the Hoisting Machine Laboratory of the Technische Hochschule in Vienna. (Die Seilprüfmaschine des Lasthebemaschinen-Laboratoriums der Technischen Hochschule in Wien.) FRANZ LIST. *Zeitschrift des Österreichischen Ingenieur- und Architektenvereins,* Vol. 84, Aug. 26, 1932, pages 177-178. Illustrated description of a new type of rope testing machine. GN (6)

Characterization of the Mechanical Properties of Molded Cast Iron Specimens. (Caractérisation des propriétés mécaniques des pièces moulées en fonte grise.) A. PORTEVIN. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 39-55. The author argues in favor of testing specimens from actual castings, as by the shear test, and
1 advocates standardization of specimens for this test and for its correlation with older methods of testing. 61 references. HWG (6)

Bending Tests on Geometrically Similar Notched Bar Specimens. J. G. DOCHERTY. *Engineering,* Vol. 133, June 3, 1932, pages 645-647. Specimens ranging in size from 4x4 mm.
— to 12x12 mm. were used. The metals tested included: mild steel as rolled, normalized mild steel, normalized 3% Ni steel, annealed Monel metal, annealed Naval brass, phosphor bronze as rolled, annealed phosphor bronze, and normalized 0.3% C steel. The following bending rates were
2 used: 0.05, 6, 50, 150 in./min. and the standard Izod speed. Table is given showing the energy absorbed at various speeds and for the various sizes of specimens. Results show that energy absorbed increases with speed of test, except at highest speed in the more brittle metals. In most cases
— the energy varied with a power of the size which lay between 2 or 3 but which was usually less than 3. LFM (6)

Improved Device for Recording Instantaneous Tool Pressures in Machinability Studies. O. F. GECHTER & H. R. LAIRD. *Transactions American Society of Mechanical Engineers,* Vol. 54, June 30, 1932, Machine Shop Practice, pages 73-85. A method of
3 measuring the 3 tool-pressure components during the machining of short test pieces by means of the piezo-electric pressure measurement of a quartz cube is described in detail; the electrostatic charges produced on the quartz by the pressure are collected by Cu foils and used for charging condensers and by means of an amplifier can be read
— on a milliammeter. The whole assembly and procedure is described in detail. Results obtained in this way are reproduced in the form of curves. 22 references. Ha (6)

Tensile Testing by Means of the "Klinometer." (Festigkeitsprüfung mit Hilfe des Klinometers.) A. U. HUGGENBERGER. *Schweizerische Bauzeitung,* Vol. 99, Mar. 19, 1932, pages 151-154.
4 The construction of 2 types of the "Klinometer" and its calibration are discussed. It is shown how bending stresses are determined. GN (6)

Magnetic Effect in Metals. E. G. HERBERT. *Electrical Review,* Vol. 110, Feb. 12, 1932, page 232. Author has developed a
— stabilizing magnetic process for rendering permanent any selected phase of fluctuations set up by the rotary magnetic process, or by thermal or mechanical means. Presents curves illustrating application of the rotary and stabilizing processes to Co high-speed steel. In one case steel was given
5 1 turn in the magnetic field at 150° C., aged to maximum hardness and stabilized 3 min. in a stationary field. Resulting hardness was high above previous maximum. In the second, steel was given 1 turn at 200° C., aged to minimum phase, and stabilized 3 min. in a stationary field, with stability below previous minimum. Latest magnetic table for applying processes provides a powerful field in a gap
— 12″ long and adjustable in width, or, by reversing the tables, a more concentrated field in a short gap of varied width. In the rotary treatment, specimen is placed across the gap and rotated once, so as to change the direction of polarization through 360°. High-speed steels are usually treated hot, most favorable temperature depending on the
6 characteristics of steel, but generally not above 250° C. Stabilizing process is applied cold, and consists in placing specimen across the gap for a minute or more. Stabilization must be carried out a specific number of hours after rotary treatment. MS (6)

The Measurement of the Depth of the Impression in the Hardness Test. (Beitrag zur Eindrucktiefenmessung bei der Härteprüfung.) E. FRANKE. *Die Messtechnik,* Vol. 8, July 1932, pages 151-155. The accuracy of the measurement of the depth of an impression made by a ball or cone is shown to depend to a certain degree on the thickening of the edge of the impression. A method is developed which permits taking
7 the influence of the thickened zone into account and arriving at constructions of depth measuring instruments giving accurate indications. Ha (6)

Tensile Properties of a High-grade Electric Arc Welding. (Festigkeitseigenschaften einer hochwertigen Lichtbogenschweissung.) G. CZTERNASTY. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, July 9, 1932, pages 679-682. The tests carried
— out by hydraulic pressure in an electrically welded boiler until bursting are fully described. Ha (6)

Experiments on the Theory of Deformation by Slip. (Einige Versuche zur Theorie des schichtweisen Fliessens.) HEINZ MUSSMANN. *Metallwirtschaft,* Vol. 11, July 1, 1932, page 371.

Low C steel bars were normalized at 975° C., then heated for 1 hour in oil at 200° C. and cooled slowly. The bars were stressed under tension until the metal began to flow at the yield point. The load was then released and the bars heated again for 1 hour at 200° C. and stressed under tension again. The yield point occurred at the same load. This was repeated several times with no change in yield point, until the point was reached where the steel increased in strength due to cold working, when the yield point was considerably increased. These results are in accord with the theory of deformation by slip. CEM (6) 1

Problems of Material Testing. (Materialprüfungsfragen.) A. LEON. *Zeitschrift des Österreichischen Ingenieur-und Architektenvereins,* Vol. 84, July 15, 1932, pages 144-145.

The paper discusses calibrating of testing machines and tests on elasticity, plasticity, toughness, brittleness, hardness, machinability, notch toughness, fatigue strength, creep limit, the use of the microscope, photoelastic methods and X-rays. GN (6) 2

Modulus of Elasticity of Aluminum Alloys. R. L. TEMPLIN & D. A. PAUL. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 480-486.

See *Metals & Alloys,* Vol. 1, Dec. 1930, page 909. (6)

The Brown Boveri High Power Testing Plant. H. THOMMEN. *Brown Boveri Review,* Vol. 19, May/June, 1932, pages 115-129.

The testing plant at the Brown Boveri works is one of the largest of its kind. A detailed description of the equipment is given. It serves for the development of high capacity circuit breakers, is used for testing fuses, inductances, current transformers, relays, bus-bar models, etc. with regard to their ability to withstand short circuits. The majority of the tests are devoted to researches on the phenomena in apparatus in process of development. An effort has been made to prevent the researches from being disturbed by acceptance tests on standard apparatus. Some particulars on the results of tests are given. MAB (6) 3

The Method for the Technical Cohesion Determination. (Die Methodik der technischen Kohäsionsermittlung.) W. KUNTZE. *Metallwirtschaft,* Vol. 11, June 17, 1932, pages 343-347. 4

16 references. The ordinary tensile test produces a fracture with deformation of the metal, while in industrial failures of metals fracture usually takes place without deformation due to a combination of stresses. To determine the "parting strength" without deformation a tensile test on a notched test piece is proposed and the principles of this test are discussed. The parting strength St is equal to

$$s_B + \frac{s_{\omega K} - s_B}{1 - K} \times \frac{180}{180 - \omega}$$

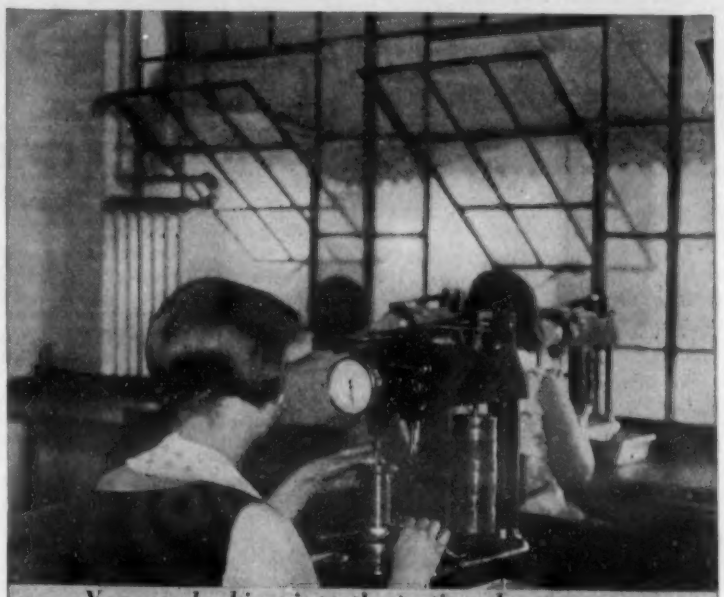
where s_B = the regular tensile strength, $s_{\omega K}$ = the strength determined on the notched test bar, K = the ratio of the areas of the notched section to the test bar section, and ω = the angle of the notch. The optimum dimensions for the notched test bar are notch dia. = 3 mm, test bar dia. = 10 mm, K = .09, ω = 135°, and radius of the point of the notch = .1 to .15 mm. Some metals are more sensitive to differences in the dimensions of the notch than others. To determine this another notched bar of the same dimensions except with a 60° notch is tested. The sensitivity of the metal is equal to the differences between the results obtained on the 2 test bars. CEM (6) 5 6

Does the Rockwell Test Fail in Case-Hardening? (Versagt die Rockwellprüfung bei Einsatzhärtung?) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Aug. 21, 1932, page 444.

The Rockwell test gives lower values than the most probable ones when the case thickness is below .4-.5 mm. The following results were obtained on a case carburized .18% C steel. 7

Carburizing Temp.	Carburizing Time hr.	Depth of hardened zone mm.	Depth of case mm.	Hardness of case R_C	Hardness of core Brinell
950° C.	1	.26-.30	.6- .7	49-53	225
950° C.	3	.30-.45	1.0-1.3	59-63	231
950° C.	5	.60-.91	1.4-1.8	63-65	212
900° C.	3	.36-.45	.8-1.0	52-62	205
900° C.	5	.60-.68	1.1-1.3	65-67	213

The above table indicates the fluctuations of Rockwell C due to the diamond pressing through the thin case. In such cases Rockwell testers are to be calibrated anew on the base of comprehensive tests. The German Federal Railway checks Rockwell readings with the Shore tester. GN (6)



The Resonance Curve as the Base of Dynamic Investigations. (Die Resonanzkurve als Unterlage für dynamische Untersuchungen.) W. SPÄTH. *Ingenieurarchiv,* Vol. 2, Jan. 1932, pages 651-667. 8

In order to judge the dynamic properties of elastic constructions (bridges, ships, foundations, frameworks, etc.) systematic measurements are carried on by means of artificially excited vibrations. The results of such measurements at various frequencies of the power exciting can be represented in resonance curves as is done for electrical oscillations. The most essential properties of the laws on resonance as well as the peculiarities of the practical measurements of mechanical systems of vibration are discussed and compared with the corresponding electrical occurrences. 10 references. New Means for Supervision of Large Continuous Baths. (Neue Hilfsmittel zur Ueberwachung grosser kontinuierlicher Bäder.) C. Huetter. *Oberflächentechnik,* Vol. 9, May 3, 1932, pages 87-88.

The continuous regulation of electrolytic baths for keeping the pH-value or conductivity constant is carried out automatically. A little cell built into the electrolyte is continually compared with a standard cell; connections from both go to recording instruments and the deviations of the former cell from the standard actuate the regulator for the valves which admit additional solution or fresh electrolyte. A few examples are described. Ha (7a)

Factors Affecting the Smoothness and Mechanical Properties of Electro-Deposited Copper. A. W. Hothersall. *Preprint, Electroplaters & Depositors Technical Society,* London, Mar. 1931, pages 95-122.

32 references. The Brinell hardness range of Cu deposited under widely differing conditions from acid copper sulphate solutions free from organic matter is narrow, the maximum and minimum figures obtained being 63 and 38 respectively. There is considerable tendency for the formation of rough and nodular deposits at high current densities. Growth or nodules may be caused by the presence of certain impurities, but in general are due either to preferential crystal growth or favorably situated nuclei, or to projecting crystal facets, or to adherence to the cathode of electrically conducting particles which may thus constitute projecting nuclei. Once the preferential growth has commenced, rapid increase in the rate of deposition on the prominent points occurs, especially at high current densities, owing to the steep potential gradient through the solution. The relatively small increase of polarization with current density, characteristic of acid copper sulphate solutions free from organic matter, offers little hindrance to this increased rate of growth. Two methods are available for reducing the tendency for rough deposits at high current densities, (1) suitable movement of the solution relative to the cathode and (2) the use of addition agents. Addition agents which give smooth deposits also increase the hardness, and in some cases the ductility of the deposit. No addition agents are available which would work at high current densities, and yet produce a soft deposit. Examination of the mechanical properties of deposits formed under various conditions in solutions containing different addition agents shows that dextrin tends to promote formation of brittle deposits, and gelatin, peptone and phenol markedly improve the smoothness ductility and hardness of Cu deposits. The concentration of either gelatin or peptone is too small for chemical control, but phenol may be used as much as 10 g./l. and can be controlled chemically. LCP (7a)

Electrodeposition of Platinum, Palladium and Rhodium. W. Keitel & H. E. Zschiegner. *Transactions Electrochemical Society,* Vol. 59, 1931, pages 273-275.

The Electrodeposition of Ternary Alloys of Copper Cadmium and Zinc from Cyanide Baths. R. C. Ernst & C. A. Mann. *Preprint, The Electrochemical Society,* Vol. 61, Apr. 1932, pages 153-184.

Theories and principles involved in the simultaneous electrodeposition of 2 metals from aqueous baths are reviewed and extended to the deposition of an alloy of Cu, Cd and Zn. The deposition may be carried out in the following bath: CuCN 40.01 g./l.; Cd $(CN)_2$ 2.94 g./l.; $Zn(CN)_2$ 36.14 g./l.; KCN 138.0 g./l. This bath gives a deposit containing approximately 62% Cu, 21% Cd and 17% Zn at 25° C. and 0.3 amp./dm.^{2} The effect of KCN, $NaHSO_3$, NaOH, current density, temperature and dilution on the composition and properties of the deposit were studied in detail and given in tables and curves. High temperature favors Cd deposition and low temperature favors Cu deposition, but temperature has practically no effect on Zn. KOH favors Zn deposition and retards Cu deposition, but has no effect on Cd deposition. KCN retards Cu deposition, while it promotes Cd and Zn deposition. LCP (7a)

Chromium Plating Light Alloys. (Das Verchromen von Leichtlegierungen.) K. Altmannsberger. *Chemiker-Zeitung,* Vol. 56, Mar. 26, 1932, page 247.

For the preparation of the Al surface the following solution is recommended: Dissolve 300 g. sheet Zn in 5 kg. hot NaOH solution of 30-35° Be., let stand 4 hours, add 100 g. ZnO, boil and cool. The parts to be plated are first cleaned electro-chemically to remove oil, then dipped in the zincate solution at 40-45° C. until silver white Zn is deposited. 5 Al alloys of different compositions were plated as a test. They were first polished, the Al-Cu alloys polishing better than the Al-Si alloys which were rough and dark. After the Zn dip they were Ni plated in a solution containing 34.5 g. Ni/l. at 1.8 amps./dm.^{2} and 3.8 volts, then Cr plated in 406 g. CrO_3/l. and 3.66 g. H_2SO_4/l. at 41° C. and 3.8 volts for 3 minutes. All samples were perfect. On other samples Cu plated in cyanide solution instead of dipped in zincate solution, but otherwise treated similarly, the Cr came off the edges. Al alloys plated with Cr directly oxidize and become gray. CEM (7a)

Recent Advances in Metal Protection. *Brass World,* Vol. 28, 9 Aug. 1932, pages 161-162.

A review of the work of some important investigations on Cd and Zn electrodeposition on light metals, and immersion coatings. WHB (7a)

Progress in the Electrodeposition of Tin. *Tin,* June 1932, pages 10-11.

Tin plating as a means for protecting Fe or steel against corrosion is discussed in general and it is explained that an effectively coated metal acts as a single metal while, if the coating is discontinuous, the base and the discontinuous coating act as 2 metals which are liable to corrode by forming a couple and causing electrolytic action. Testing methods of tinned material for effective coating are described and it is stated that present methods of electrodeposition of Sn on Fe and steel plate are entirely successful both from the commercial and the mechanical point of view. Ha (7a)

Chemical Control of Cyanide Silver Plating Solutions. R. M. WICK. *Monthly Review, American Electroplaters Society,* Vol. 19, July 1932, pages 5-10.

Analytical procedure for the determination of free cyanide, silver and carbonate. See also "The Analysis of Cyanide Silver-Plating Solutions," *Metals & Alloys,* Vol. 3, May 1932, page MA 129. LCP (7a)

The Lead Plating Methods, in particular, Homogenous Lead Lining. (Die Verbleiungsverfahren, insbesondere die homogene Verbleiung.) H. KRAUSE. *Feinmechanik und Präzision,* Vol. 40, June 1, 1932, pages 106-108.

The methods for obtaining a dense, non-porous, sufficiently thick and uniformly thick coating of Pb especially on Fe or steel surfaces are reviewed. Besides the older methods of lining by first tinning and then melting the desired thickness on the surface, recently electrolytic methods have been developed even for thicknesses up to 10 mm. Electrolytically deposited Pb is softer than the melted-on Pb; with this method metals like Al or cast Fe can be leaded for which the melting method fails. They must be properly cleaned by sand-blasting. Cu and Cu alloys must first be Ni plated or tinned. A Pb thickness of 0.075 mm. is generally sufficient for a dense coating; for chemical apparatus 1.75 mm. High voltage and high current density give best results, otherwise the coatings may be porous. Thinner coatings can be produced in alkaline baths, thicker ones are now made in silico-hydro-fluoric, boro-hydro-fluoric and perchlorate baths; in addition the following electrolyte is recommended: 8.25 kg. lead silico-hydro-fluoride, 7 kg. silico-hydro-fluoric acid, 10 g. gelatine, 100 l. H_2O. Current density about 1 amp./dm.^{2}, bath voltage 0.15 to 0.2. Ha (7a)

Electrodeposition of Silver from Sulfate, Nitrate, Fluoborate and Fluoride Solutions. EDWARD B. SANIGAR. *Transactions Electrochemical Society,* Vol. 59, 1931, pages 307-327.

Plant Practice for Nickel-Plating Aluminum. A. V. RE. *Preprint, The Electrochemical Society,* Vol. 61, Apr. 1932, pages 139-141.

Satisfactory, thoroughly adherent electrodeposits of Ni on Al articles may be obtained by carefully cleaning the surface in a hot alkaline peroxide bath followed by a strong H_2SO_4-HNO_3 bath, containing $FeCl_3$, flashing with brass and finishing with a standard Ni bath. The under-coat of brass greatly increases the uniformity and adhesion of the electroplate to the Al surface. Full directions of procedure are given. LCP (7a)

European Practice of Nickel Plating. (Europäische Vernicklungspraxis.) *Werkzeugmaschine,* Vol. 36, July 15, 1932, pages 244-246.

Semi- and completely automatic Ni plating finds increasing use in Germany. Plating baths of high efficiency are used in all European countries. Particularly in France and Belgium hot Ni baths with a high content of Ni are used, but Germany prefers automatic Ni plating. In Italy medium current densities are preferred. A survey of the Ni plating practice of the most important European automobile manufacturers is given. GN (7a)

The Determination of Output in Electroplating Plants. (Zur Leistungsermittlung in Betrieben der Galvanisierung.) P. F. WINTERSBERGER. *Oberflächentechnik,* Vol. 9, July 5, 1932, pages 135-136.

The calculation of a certain output-factor for the determination of the efficiency in an electroplating plant is explained with particular reference to Ag plating. This factor is a quotient of weight of deposited metal divided by the number of labor hours. The determination of these 2 factors is discussed and illustrated by an example, taking into account different qualities of the product. Ha (7a)

Electrometallurgy (7b)

Electrolytic De-tinning. (Elektrolytisches Entzinnen.) *Emailletechnische Monatsblätter,* Vol. 8, July 1932, page 52.

Description of a new method for reclaiming Sn from Sn sheet scrap. A solution of caustic potash is used as electrolyte which contains certain ingredients for avoiding the simultaneous removal of Fe. Sn is deposited and goes in the slime of the Fe cathodes. The slime is melted and gives Sn of 99.7% purity. GN (7b)

The Production of Zinc by Electrolysis. (II) HARRY HEY. *Chemical Engineering & Mining Review,* Vol. 24, Mar. 5, 1932, pages 197-205.

Electrolysis of $ZnSO_4$ solution is effected under the general conditions of: (1) the so-called low-acid, low current density process where the feed solution contains 100-150 Zn./l., H_2SO_4 90-140 g./l., and current density of 25-45 amp./ft.^{2} and (2) the Tainton high-acid, high current density (100 amp./ft.^{2}) process. 9 variables which affect current efficiency or cell voltage, or both, are: current density, acidity, Zn concentration, anode material, temperature, length of deposition period, spacing between electrodes, addition agents, and impurities in the electrolyte. Toxic impurities of $ZnSO_4$ electrolytes include Sb, Co, As, Ni, Cu and Ge. Mn tends to reduce the conductivity of the electrolyte, increasing the cell voltage. K-, Na- and Mg-sulphates affect the conductivity, Cd reduces the grade of Zn. Pb, like Cd, may deposit with the Zn. Curves show the factors affecting current efficiencies of Co bearing solutions. Electrodes, melting and casting, and treatment of residues are discussed. The following features should be explained: (1) the reason for the observed effects of toxic impurities, (2) the manner in which glue and other addition agents restrain the toxicity of Co and similar impurities, (3) the anode reactions, and (4) the reason impurities, particularly Sb, modify the structure of the deposited Zn. WHB (7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Mechanical Aids to Hot Galvanizing. WALLACE G. IMHOFF. *American Machinist,* Vol. 76, May 12, 1932, pages 616-618.

The treatment of steel and Fe before dipping into the hot Zn in order to obtain a properly adhering Zn coating is discussed and practical hints are given. A flux treatment and heating to 850°-875° F. is recommended, the Zn bath should have at least 850° F. for large production and for slow work at least 825° to 850° F. Soldered articles must show perfect seams as the Zn will not fill holes. Ha (8)

Galvanizing of Interior Surfaces of Containers. (Galvanisches Ueberziehen der Innenflächen von Behältern.) FRIEDRICH HUTH. *Emailletechnische Monatsblätter,* Vol. 8, Sept. 1932, pages 67-68.

According to German patent 536,013 this type of galvanizing is to be facilitated by using an anode similar in shape to that of the container. This means a considerable saving of electric current. GN (8)

Zinc Used in Metalware Galvanizing. WALLACE G. IMHOFF. *American Metal Market,* Vol. 39, July 2, 1932, pages 5, 8; July 6, pages 5, 8; July 8, page 5; July 9, 1932, page 5.

Discussed from 2 viewpoints: (1) the amount of Zn used, and (2) the kind of metal used. In order of quality zincs may be rated as follows: (1) electrolytic Zn; (2) primary distilled Zn; (3) secondary distilled Zn; (4) remelted Zn. The author is very familiar with this subject and the article will be interesting to refiner, mill-man and consumer alike. The following features of the metals should be carefully observed in all galvanizing work: (1) should be absolutely clean on the top surface; (2) the top surface of the metal should have a light blue color and not be yellow, bronze or purple; (3) the surface of the Zn should be very smooth and have almost a velvet-like feel; (4) an Fe content above .08% indicates that the production has been pushed, which indirectly tends to give a metal that is sluggish and one with little "life" in it; (5) the metal should not show blisters or gas cavities on the top surface; (6) generally, brittle zincs are not good for galvanizing; (7) a good high quality Zn will show a clean, bright fracture with very large bright crystal faces—the fracture should not be observed at the chill marks of the slab, but across the full thickness of the slab; (8) the chemical analysis is only an indicator of the quality of the metal and is not a final or definite answer as to the quality of the Zn; (9) high quality Zn has a mirror-like surface which retains this "mercury-like" appearance for a long time. DTR (8)

Magnesium Alloy Protection by Selenium and Other Coating Processes. G. D. BENGOUGH & L. WHITBY. *Journal Institute of Metals,* Vol. 48, 1932, pages 147-163; *Korrosion und Metallschutz,* Vol. 8, Apr. 1932, page 93.

Includes discussion. See *Metals & Alloys,* Vol. 3, Oct. 1932, page MA 300. EF (8)

Metal Spraying. (Das Metallspritzverfahren.) WALTER HAHN. *Apparatebau,* Vol. 44, Sept. 16, 1932, pages 126-127; Oct. 14, 1932, pages 146-147.

The paper discusses advantages and application of metal spraying, with special reference to Al coating for various purposes. Combined Al-Zn coatings and zinc coating of small Fe articles are discussed. Use of such coatings in case-carburizing to protect areas not to be case hardened is considered. Elimination of defects and pipes in steel and non-ferrous metal castings is finally dealt with. GN (8)

Metallic Depositions Without External Source of Current. (Metallabscheidungen ohne äussere Stromquelle.) A. KUTZELNIGG. *Zeitschrift für Elektrochemie,* Vol. 38, Mar. 1932, pages 154-158.

The methods and mechanism of depositing metals in thin layers by simply immersing a metal in a solution are discussed; the solution can be cold or hot, or the metal is "rubbed" onto the surface. The position of the 2 metals in the series of electrical potentials determines the success of the process. Various methods and solutions for depositing Au, Ag, Cu, Sn are described. 28 references. Ha (8)

Modern Galvanizing. (Neuzeitliche Verzinkung.) L. ARNDT. *Zeitschrift für die gesamte Giessereipraxis, Eisenzeitung,* Vol. 52, Nov. 22, 1931, pages 395-397.

Detailed description of the 2 hot galvanizing processes, the wet or salammoniac process and the dry process. A thorough cleaning, mechanically or better chemically, is prerequisite to a successful galvanizing. The extent of pickling and the use of inhibitors are considered. In hot galvanizing, 2% Al are added to the Zn bath, to improve the corrosion resistance. The Zn consumption has been cut down to less than 1 kg. Zn/2m.^{2} of galvanized area. Additions of Sn, Bi, Sb and other metals induce an "ice flower" appearance on quenching. The best working temperature is 440°C. At 491.5°C. a glossy coating is obtained. The critical temperature is 510°C. which should never be passed. The articles are kept in the melt until they attain the temperature of the latter. The second part of the paper is devoted to the wet galvanizing process. The economy, operation, composition of the electrolyte and the mechanism of alkali and cyanide galvanizing are discussed. EF (8)

X-Ray Investigations of Electrolytically Oxidized Aluminum. (Roentgenographische Untersuchungen an elektrolytische-oxydiertem Aluminium.) E. SCHMID & G. WASSERMANN. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Apr.-June 1932, pages 100-106.

The nature of the Al oxide films produced electrolytically was investigated by X-rays. 4 modifications of Al hydroxide are known of which 2, Bayerite and Hydrargillite, have the constitution $Al_2O_3 \cdot 3H_2O$. The 2 others, Boehmit and Diaspor, have the constitution of $Al_2O_3 \cdot H_2O$. The last one has so far not been produced artificially and is, therefore, very likely not contained in the electrolytically produced oxides. X-ray pictures and characteristics at different temperatures are reproduced. Eloxal, the technically used oxidation for Al, consists of γ Al oxide of crystalline, very fine grained structure. Up to 400° C. the diagram of Eloxal is not greatly changed but annealing at 600° C. and higher show the diagram of γ oxide with collective crystallization. A treatment of Eloxal with high-pressure water vapor converts it into Boehmit. The crystallizability of the hydroxide is greater than that of the oxide. 19 references. Ha (8)

Nickel Clad Steel Plate for Equipment. Erle G. Hill. *Chemical & Metallurgical Engineering*, Vol. 39, May 1932, page 268.

A new Ni clad steel plate with a bright face free of nickel-oxide is now available in sheets of extra heavy weight and very large size. PRK (9)

Experiments with Ball Bearings of Stainless Steel. (Versuche mit Kugellagern aus nicht rostendem Stahl.) Walter Heinen. *Die Chemische Fabrik*, Vol. 5, May 4, 1932, pages 140-142.

For ball bearings which cannot be lubricated properly or which run in a corrosive liquid or atmosphere it is of great advantage to use a non-rusting steel. It is not possible to electroplate the balls or apply a protective coating to them which will withstand the wear. Tests were made on a medium size ball bearing in which the balls and race were made of V3MH stainless steel. The Rockwell hardness of the balls was C 59 and of the race C 57. Those made of standard steel have a hardness of C 62 and C 65. The load on the bearing was 120 kg. When run in water without oil the ball bearing lasted only a few hours. With a mixture of 70 parts of water to 1 part of oil the bearing ran 800 hours without harm, but the play was increased. With the 70:1 lubrication and iron rust introduced from other steel parts the bearing lasted for 164 hours and then began to crumble on the surface. Stainless steel ball bearings are satisfactory if they receive at least a small amount of lubrication and if they are kept free from rust from other parts. Their load carrying capacity is somewhat less on account of their lower hardness. CEM (9)

Platinum and Its Alloys in Dentistry. (Platin und seine Legierungen in der Zahnheilkunde.) Karl Falck. Festschrift zum Fünfzigjährigen Bestehen der Platinschmetze (1881-1931). G. Siebert, G. m. b. H. Publisher G. M. Alberti's Hofbuchhandlung, Hanau, pages 31-50.

In 1927 the world production of Pt was 5,675 kg. of which dentistry used 850 kg., or 15%. Pt pins or hooks were used in porcelain or mineral teeth as early as 1808. The S. S. White Co. in America was founded in 1844, and America became the leading manufacturer of artificial teeth till 1914, when the world production was about 120 million, of which America produced 65-70%. The world production in 1929 was about 700 million. Pt pins are used as a means of attaching the tooth to the vulcanite. Falck estimated that in 1914 about 1575 kg. of Pt was required as different kinds of attachments for artificial teeth, but the actual amount used was less, due to the use of substitutes for Pt. Other uses of pure Pt in dentistry include shells for holding the pins, crowns, matrices for porcelain inlays and porcelain-jacketed crowns, and rings or bands. For these purposes sheets of 0.15 to 0.2 mm. in thickness are generally used. A Pt-solder contains 82% Ag. 17.5% Pt, and 2-3% Cu. In place of Pt, alloys have been used, such as Pt with 2% Ir, 25% Pt and 75% Au, Pd with Au, and Ni with a gold plate. Falck reports the yield strength and breaking strength in kg./mm.^{2} for 3 alloys: Pt with 2% Ir, 5-6 and 9.0; Ni with Au plate, 7-8 and 17.6; 18 karat Pt-Au (Primodor) 11-12 and 19.3 respectively. These tests were on wire of 0.7 mm. diameter which had been heated 2 min. at 800° C. Pt is added in small amounts of the alloy used in amalgams and improves the properties and color. Pt is used in making heating elements for electric furnaces and in thermocouples. Pt is used as an alloying element with Au and especially with Au-Ag-Cu alloys. Replacing 5-6% of Au with Pt raises the Brinell hardness from 70 to 160. Replacing 5% Au in a 20 karat alloy with 5% Pt greatly refines the grain. The properties and uses of alloys of 18-20 karat containing up to 25% Pt are discussed in the last 5 pages and 4 photomicrographs are given. OEH (9)

Nickel Cast Iron in the Diesel Engine. A. B. Everest. *Gas & Oil Power*, Vol. 26, Nov. 5, 1931, pages 335-336; *Transactions Institute of Marine Engineers*, Vol. 43, Dec. 1931, pages 554-555.

A brief exposition of the technical and practical value of Ni-bearing cast Fe for heavy oil engine work. (9)

Marble and Metal. E. H. Faile. *Metalcraft*, Vol. 8, Mar. 1932, pages 104-109.

In the 11 story Goelet Building at 608 Fifth Ave. New York, Al was used to make an attractive design with the marble in the interior of the building. Al was also used in the exterior of the building wherever metal was necessary. In such a building, Portland cement mortar and not lime mortar must be used as the latter is corrosive to the metal. Anchors of Al or at least galvanized material should be used. Al should also be painted on the back side with an asphaltum paint. VVK (9)

Specifications for Architectural Aluminum Work. *Metalcraft*, Vol. 8, Apr. 1932, pages 168-170.

The general specifications and requirements, standards of materials and workmanship, etc. in Al work worked out by E. H. Faile & Co. for use in the Goelet Building, N. Y. See abstract above. VVK (9)

Seadrome Project Requires 17,000 Tons of Iron, Steel. A. H. Allen. *Steel*, Vol. 90, Feb. 15, 1932, pages 28-29.

After 17 years of development work, plans have been completed and approved for the construction of the first mid-ocean seadrome, to be located about 350 miles from New York on the New York-Bermuda steamship route, at an estimated cost of $4,000,000. 7 additional seadromes are contemplated at 500-mile intervals on the southerly route between New York and Europe. These seadromes will be equipped to provide every convenience and necessity for aircraft and trans-oceanic passengers. JN (9)

Extra Long Cylinder Piles Carry Column Loads to Rock. W. T. McIntosh. *Engineering News-Record*, Vol. 109, July 7, 1932, pages 5-7.

Study of ground conditions for Sterrett-Lehigh manufacturing and distribution center building in New York City led to conclusion that a foundation of steel pipe piles to rock was best suited to the conditions. Steel-pipe pile foundations consist of groups of steel cylinders driven with open ends to rock, excavated, cut off at the required grade, filled with concrete and capped with reinforced concrete. The cylinders are generally 10 to 18" in diameter, with ⅜ to ½" shells. They are of seamless or lap-welded steel tubing, generally 20 to 30 ft. long. When longer piles are required, two or more lengths are joined together with internal or external sleeve couplings. Tests show that settlement of ⅛" under 1½ times the designed load have taken place and the steel-pipe pile foundation is entirely satisfactory. CBJ (9)

Steel—Its Principal Problem. Charles F. Abbott. *American Metal Market*, Vol. 39, Feb. 18, 1932, pages 6-7.

Light Metal Alloy Pistons and Rods in High-Speed Industrial Engines. B. J. Isidin. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, *Oil & Gas Power,* pages 109-115.

As a satisfactory means of reducing the weight in pistons and rods of modern high-speed internal combustion engines the use of Al is discussed which allows heavier sections and thus preserves the rigidity and removes thermal difficulties which are encountered with steel or cast Fe parts of reduced section. Diagrams showing the force and stresses at the different strokes with different materials and speed are developed showing the better behavior of Al and its alloys. See also *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 246. Ha (9)

Nickel-Chromium Cast Iron Dies. Herbert Chase. *American Machinist,* Vol. 76, Jan. 7, 1932, pages 11-14.

Cast Fe alloyed with Ni and Cr is used for stamping, pressing and forging operations. It is used in working both ferrous and non-ferrous sheet. Dies made from this cost less initially than hardened steel dies and in many cases last longer. They are fine grained, take a high polish, and largely eliminate galling of pressed parts. Dies should be heat-treated. Hardness may range from 200 to 400 Brinell. Tensile strength may run up to 50,000 lbs./in.^{2} A table is given showing 14 possible compositions and showing heat treatment for each. RHP (9)

Nitriding Steels. H. A. Defries. *American Metal Market,* Vol. 38, Dec. 12, 1931, pages 9, 10.

Presented at Conference on Metals and Alloys, Cleveland, Nov. 18-20, 1931. See *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 249. DTR (9)

Materials for Bearings. (Über Gleitlager- Werkstoffe.) E. Becker. *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, June 19, 1932, page 328.

After dealing with the requirements that bearings have to meet, the most important materials are discussed: normal bronzes, lead bronzes, white metal, Pb-alkali earth metals, high graphite cast Fe, and a bronze of high porosity which is able to take up large quantities of oil, as it has been developed recently in U.S.A. GN (9)

The Commercial Use of Acid- and Corrosion-Resisting Steels. C. M. Carmichael. *Canadian Chemistry & Metallurgy,* Vol. 16, Aug. 1932, pages 218, 220, 222.

A general discussion of stainless steels. The handling of these is outlined and the need of a method of welding without additional heat treatment pointed out. Welding, shearing, punching, drilling, sawing, machining, threading and tapping are discussed. WHB (9)

Evolution of Metal Construction. Gardner W. Carr. *Paper presented before the American Society of Mechanical Engineers,* Aeronautic Division, Buffalo, June 1932, 7 pages.

The all-metal construction of airplanes is now apparently accepted as the standard; the development of this type, different designs and materials used are reviewed and the present status of construction and special alloys available are discussed. Ha (9)

Copper in Refrigeration Apparatus. (Le Cuivre dans les Appareils de Refrigeration.) A. Chaplet. *Cuivre et Laiton,* Vol. 5, June 15, 1932, pages 261-262.

Describes some French refrigerating machines where Cu parts are used extensively. Ha (9)

Steel Brake Drums are Lined with Centrifugally Cast Iron. Edward W. Beach & Edwin Bremer. *Steel,* Vol. 90, Mar. 14, 1932, pages 31-34.

A description of a new and improved type of brake drum for automobiles. This consists of a pressed steel drum with a lining of cast Fe in intimate combination with the steel. In manufacturing these drums, a double-width steel band is heated to a predetermined temperature, accurately placed in a specially designed high-speed centrifugal casting machine, and spun at a high speed while molten metal is introduced at the proper temperature to ensure actual fusing of the 2 metals. The drum is then cut along the mid-line by a special machine to produce 2 duplicate brake drum rings. The individual machinery developed for fast and accurate production and the process of manufacture are described. JN (9)

The Merits of Steel Pipe for Water Mains. John L. W. Birkinbine. *Journal American Water Works Association,* Vol. 24, Mar. 1932, pages 345-356; Discussion, Apr. 1932, pages 575-577.

The merits of steel pipes for water mains are discussed from the standpoint of reliability, i.e. the possibility of failure by (1) fracture, (2) exterior corrosion, (3) interior corrosion and (4) electrolysis; efficiency, i.e. the probable life, the carrying capacity of a pipe line, the changes in delivery following years of use and the losses through joints by leakage; adaptability, i.e. variations in the composition of steel to meet certain conditions, differing requirements demanded by installation of mains, the methods of joining lengths, specials and tapping for service connections; and economy, a discussion of cost figures. VVK (9)

The Use of Zinc and Zinc Alloys in the Automotive Industry. Robert M. Curts. *S. A. E. Transactions,* Vol. 26, 1931, pages 608-619, 641.

See *Metals & Alloys,* Vol. 2, Sept. 1931, page 176. (9)

Cast Iron Pipe for Transmission and Distribution of Water Supplies. Philip Burgess. *Journal American Water Works Association,* Vol. 24, Mar. 1932, pages 357-368.

The use of cast Fe pipe for water mains is discussed from the standpoint of cost, relative carrying capacity, corrosion, the ability of the pipe line to withstand interior pressures or to withstand the forces induced through outside agencies such as back-filling and traffic loads, other physical properties, and pipe connections. VVK (9)

Stainless Steel. M. J. R. Morris. *American Metal Market,* Vol. 38, Dec. 5, 1931, pages 7, 9.

Presented at Conference on Metals and Alloys, Cleveland, Nov. 18-20, 1931. See *Metals & Alloys,* Vol. 3, July 1932, page MA 215. DTR (9)

1 **Illinois Mine Tests Establish Advantages of Tipping Bits with Abrasion-Resisting Alloy.** A. F. Brosky. *Coal Age,* Vol. 37, July 1932, pages 259-260.

Cutting-machine bits are tipped with Blackor, a tungsten carbide compound having an excess of carbon which serves as a reducing agent in subsequent metallurgical operations. The material is applied by electric welding and followed by heat-treatment in electric muffle furnace. Operating statistics show conclusively the value of using the hard abrasion resisting material for the machine bits. CBJ (9)

2 **Economies Through New Types and New Uses of Materials.** R. E. Hobart. *Mining Congress Journal,* Vol. 18, July 1932, page 39.

Discussion of economics resulting through use of Cr steel, bronze, Monel metal, etc. as substitutes for different steel parts in the preparation of anthracite coal. DTR (9)

A Modern Metal Merges With the Classical. R. T. McCartney. *Metalcraft,* Vol. 8, Mar. 1932, pages 114-116, 133.

Al is used in the St. Clair Savings & Trust Co. building, Pittsburgh, Pa. to harmonize with the white marble used in the interior. VVK (9)

3 **Developments in Aluminum Alloys in Relation to Economies in Aircraft Construction.** C. F. Nagel, Jr. & G. O. Hoglund. *Paper presented before the American Society of Mechanical Engineers,* Buffalo, June 1932, 6 pages.

The mechanical properties and corrosion resistance of available Al alloy structural materials are reviewed and the status of technical information and fabricating situation, equipment, methods of forming, jointing and corrosion prevention are discussed. Comparative data are given for riveted and spot welded joints of Alclad 17ST material which shows almost throughout the superiority of the welding process. Corrosion is prevented mainly by an anodic treatment and painting afterwards. Improved materials will make possible construction of more efficient aircraft. Ha (9)

4 **Metallization of Wood Opens New Uses.** M. Naphtali. *Chemical & Metallurgical Engineering,* Vol. 39, May 1932, page 269.

Impregnating wood with Pb, Sn, or their alloys increases its specific gravity, with little effect on tensile strength but with an increase in hardness and compression strength. This material shows up to special advantage in exposure to moisture or to fire. PRK (9)

Modern Materials for Dye-House Equipment. J. F. Springer. *Textile Colorist,* Vol. 53, Sept. 1931, pages 617-620.

5 Deals with the use of Ni and Ni-bearing alloys, particularly the super-stainless 18-8 Cr-Ni steel, pure Ni and Monel metal in dye-house equipment. Table shows comparative resistances to corrosion of ordinary C steel, stainless steel (13% Cr), and the super-stainless steel (18% Cr, 8% Ni) in a long series of reagents. (9)

Steel Used in Making Die Blocks. Bernard Thomas. *Heat Treating & Forging,* Vol. 18, June 1932, pages 353-356.

Discusses various types of die steels and their suitability for various classes of work from the point of view of unit production costs. For dies subject to intense pressures over the whole of the impression in the cold, highest grade of
6 steel marketed as "Cold-Die," which has a fair percentage of Co, is justified. For deep-drawing dies, bulk of die may be made of plain-C steel and working edges where wear takes place built-up with Co-W, Co-W-Cr alloys. Most economic steel for forming and setting dies used in manufacture of plantation hoes is plain-C steel containing 0.60% C and 0.60-0.80% Mn used in the as-forged condition. Hot dies such as those used in nut, bolt and rivet production are made preferably of W-Cr, Cr or Ni steels. If plain-C steels must be used, best procedure is to oil quench a 0.60-0.65% C steel and temper at 1000° F. for a length of time. Nitrided
7 dies give splendid results in both hot and cold work for shallow impressions and where heavy blows are not struck. Steel for forging and stamping dies is to some extent regulated by the weight of the die. For small forgings, where die-blocks do not weigh more than 250 lb., a plain 0.60% C steel will probably be best for simple shapes, 1% Ni steel for more intricate designs, and Ni-Cr-Mo steel where die is both intricate and quantity for forging large in number. For large and heavy forgings, Ni-Cr or Ni-Cr-Mo steels are suitable. In England, probably 50% of the die steel used is plain C, 30% contains 1% Ni, and remainder of higher alloys of various types. American industries probably used 20%
8 plain C, 30% Ni and Ni-Cr, 30% Cr-Mo and Ni-Cr-Mo and remainder various other high alloy types. MS (9)

New Product Broadens Field for Malleable Castings. Enrique Touceda. *Steel,* Vol. 90, Feb. 8, 1932, page 36.

This product differs from ordinary malleable Fe in that its fracture is steely instead of black and its structure shows the nodules of temper carbon uniformly distributed in a matrix of pearlite instead of the softer ferrite. Interest in the malleable Fe industry is shown by a 100-page symposium on malleable iron put out by the American Society for Testing Materials. Articles now made of malleable Fe
9 include side stakes for gondola cars, bridge guard rails, guard rail posts and blast plates. JN (9)

Development of the Specifications on Strength of Airplanes. (Entwicklung der Festigkeitsvorschriften für Flugzeuge.) H. G. Küssner & K. Thalau. *Zeitschrift für Flugtechnik und Motorluftschiffahrt,* Vol. 23, June 14, 1932, pages 313-318.

This is an abstract of report No. 278 of the Deutsche Versuchsanstalt für Luftfahrt. The historical development of the specifications on strength in airplanes is considered for the various countries. The safety factor is criticized. It seems advisable to replace the safety factor by considera-
10 tions on probability. Due to the rapid development in airplane design the specifications frequently are out-of-date. It is necessary to study the physical occurrences more extensively, in order to calculate the strength more in accordance with actual conditions. Some clues for this undertaking are pointed out. GN (9)

Recent Trends in Alloy Steels. RICHARD TULL. *Blast Furnace & Steel Plant*, Vol. 20, May 1932, pages 422-424; *Heat Treating & Forging*, Vol. 18, May 1932, pages 309-310.

Despite the decreased demand for Fe and steel products, there have been many developments in the field of alloy steels. Advances in uses of 18-8 Cr-Ni steel have been made in the food industry and construction of all metal aeroplanes and rubber-tired trolley-cars. Another development is the series of 18-8 Cr-Mn steels containing 17-19% Cr, 5-10% Mn, and small percentages of Cu or Cu and Ni. They have a silvery finish, are resistant to corrosion and oxidation and are readily worked. They exhibit great toughness at 1375°-1650° F., even after extended exposure. Much study is being given to a steel containing 4-6% Cr for applications where nominal cost and a fair degree of corrosion resistance are desired. Tests have indicated that this type has many times the life of plain C steel when subjected to moderate corrosive conditions. Concrete-reinforcing rods of this steel have been used in a dam at Alloy, W. Va., with satisfactory results. Open-hearth steel containing 3% Cr has been found particularly well adapted for use as railroad rails. Its hardness is about 375 Brinell. A steel containing substantial amounts of Cr and V has been developed for nitriding purposes. The "Cromansil" steels are attracting considerable attention among engineering steels. Recent investigations have shown that high Cr steels are far superior to plain C steel for high temperature and pressure work, and that the austenitic Cr-Ni steels are superior to the straight Cr steels. A Ni-Mo-Fe alloy has been introduced for resisting HCl. MS (9)

Municipal Building Metalized. ROLAND LINDER. *Metalcraft*, Vol. 8, June 1932, pages 227-230.

The use of bronze, cast Fe, etc. in the City and County Building, Denver, Colo. The largest bronze doors ever cast in this country weighing 10,000 lbs. each, 26 ft. high, 6 in. thick and 6 ft. 6 in. wide were installed in this building. VVK (9)

Concerning Data, Material, Conditions, Devices and Methods of Procedure Relative to Establishing Standardization in Dental Inlay Castings. C. S. VAN HORN. *Dental Cosmos*, Vol. 74, May 1932, pages 474-487.

The author praises the early work by Taggart, 1907, and by Price, 1911. As early as 1910 a compensation casting technique based upon tooth cavity temperature, available wax, and investment expansion, coordinated with gold shrinkage was developed. He reports cavity temperature ranging from 95° to 98° F., and the shrinkage of the gold in casting about 1.25%. This shrinkage can be compensated by expanding the wax pattern or by casting in an expanded investment mold. Some of the researches at the National Bureau of Standards are criticized. Two new types of casting machines developed by the author are described and a plan for further research is proposed. OEH (9)

High Pressure and High Capacity Steam Boilers, with Appendix Boiler Corrosions. (Hochdruck- und Hochleistungsdampfkessel, mit Anhang Kesselkorrosionen.) LOSCHGE. *Zeitschrift des bayerischen Revisionsvereins*, Vol. 36, May 15, 1932, pages 103-107; May 31, 1932, pages 117-119; June 15, 1932, pages 128-130.

After dealing in the first 2 instalments of the paper with the special requirements as to the construction of high pressure and high capacity boilers and describing the latest development in this field (Atmos, Benson, Schmidt, Löffler boiler) 2 remarkable instances of corrosions on high pressure and high capacity boilers are considered in the 3rd instalment. The remedies are discussed to avoid such corrosions. 15 references. GN (9)

The Position of Palladium in the Precious Metal Industry. (Die Stellung des Palladiums in der Edelmetallindustrie.) E. R. THEWS & R. W. HARBISON. *Deutsche Goldschmiedezeitung*, Vol. 35, June 4, 1932, page 232.

The hardening and embrittling effect of Au on Pt can be counteracted by Pd. The uses of Pd in the precious metal industry are enumerated. In the first place it is used for processing white Au alloys. White Au alloys which are to be improved by hardening should contain at least 7% Cu. Such white Au alloys are heated to 450° C., gradually cooled in the furnace to 250° C. and then quenched in cold water. Pd- white Au alloys which cannot be improved contain up to 30% Pt + Pd and up to 95% Pt + Pd + Au. GN (9)

Helical Springs. Materials Used, Their Composition and Mechanical Properties. Manufacturing Methods. Permissible Motion and Causes of Rupture. (Le molle helicoidali. Materiali adoperati, loro composizione e loro caratteristiche meccaniche. Metodi di fabbricazione. Sollecitazione amissibili e cause di rottura.) I. MUSATTI & G. CALBIANI. *La Metallurgia Italiana*, Vol. 24, June 1932, pages 465-484; July 1932, pages 549-572.

A résumé of the manufacturing methods and types of steel recommended. Microphotographs of various typical defects which may cause failure are shown. Flexing and torsion tests are also made and charts illustrate the results obtained. The time and temperature of springs is extremely important, as 50° difference is often enough to give poorest, instead of optimum results. In chemical composition, eutectic steels (C 0.9%) seem to give the best results. They should be low in Mn (0.3-0.5%) and contain a minimum of S or P. Higher C contents may also be used. The structure should be uniform, and free of any occlusions. A study of the properties of several representative spring steels show that the tensile and torsional strength tests give the best indication of quality. AWC (9)

PYRO RADIATION PYROMETER

SELF-CONTAINED, DIRECT READING, RUGGED AND FOOL PROOF

OVER 10,000 IN USE

Requires no connection with furnace; no accessories; no installation. ¶ Gives actual heat of material aside from furnace temperature. ¶ Always ready to tell within 3 seconds any shortcomings in your equipment. ¶ It is serving many industries where heats must be measured accurately. It has no equal. ¶ Does not require a skilled operator. Strictly automatic. ¶ Weight 25 oz., length 7 in. ¶ Temperature range: 1000°-3600° F.

Bulletins on PYRO Optical-Immersion-Surface Pyrometers and PYRO Super-Sensitive Radiation Tubes-Rapid Recorders on Request.

Case Hardening & Nitrogen Hardening (10c)

Surface Hardening of Steel. (Durcissement Superficiel de l'Acier.) J. GALIBOURG. *L'Usine*, Vol. 41, May 27, 1932, pages 25-27.

The methods of creating a surface hardness by Cr plating, Ni plating, nitriding and the measurement of the hardness are briefly explained. The mechanism of nitriding hardening and the improvement by adding Al are described. Ha (10c)

Shortening the Nitriding Process. JOHN J. EGAN. *Iron Age*, Vol. 129, Feb. 4, 1932, pages 344-346.

Includes discussion. Abstract of paper read before the Metal Congress. Describes improvements made in methods which consist in use of inert materials as packing in usual ammonia treatment and in use of special molten salt bath. The work was carried out on 2 types of steels: Nitralloy 630 and Nitralloy 125. The analyses of the steels are:

	Nitralloy 630	Nitralloy 125
Carbon	0.25%	0.26%
Chromium	1.69	1.69
Vanadium	0.63	Nil
Aluminum	Nil	0.91
Molybdenum	Nil	0.10

The process particularly recommended by the author is one in which a mixture of ammonia and nitric oxide are used. VSP (10c)

An Appraisal of Nitriding. MARCUS A. GROSSMANN. *Year Book of the American Iron & Steel Institute*, 1931, pages 106-122.

See *Metals & Alloys*, Vol. 2, Nov. 1931, page 264. (10c)

Modern Case Hardening, a Yardstick for Steel Treating. (Neuzeitliche Einsatzhärtung, ein Wertmesser der Stahlverarbeitung.) A. HERZ. *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, June 12, 1932, pages 316-318.

The paper discusses the various methods of surface treatment of steel from the standpoint of attaining highest quality. For the quality of a case carburizing mixture, its capacity to give off sufficient amounts of CO within short time is of prime importance. The depth of case is essentially affected by time and temperature of carburizing, less by the quality of the mixture. The elimination of excessive Fe_3C by the double hardening process is considered. The relations between depth of case and depth of hardness are stated. The carburizing of small articles by special rapid compounds, oil and gas fired modern case carburizing furnaces are discussed. The principles of nitriding are dealt with. GN (10c)

Case-Hardening of Steel in Molten Sodium Cyanide. H. N. BEILBY & W. NELSON. *Journal Society of Chemical Industry*, Vol. 51, May 13, 1932, pages 149-159T.

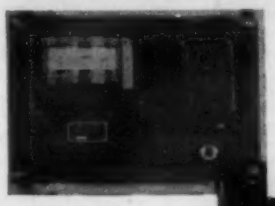
A very comprehensive article. The following topics are discussed: the Fe-C equilibrium diagram as related to case-hardening, history and theory of case-hardening, cyanide hardening, composition of bath, deterioration and maintenance of the cyanide bath, condition of case, distribution of C, heat-treatment, control of temperature, scale and decarburization, prevention of distortion, rate of heating and quenching. VVK (10c)

Aging (10f)

The Precipitation Hardening of Iron. (Ein Beitrag zur Frage der Ausscheidungshärtung des Eisens.) W. EILENDER & R. WASMUHT. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen*, Vol. 11, 1932, 6 pages.

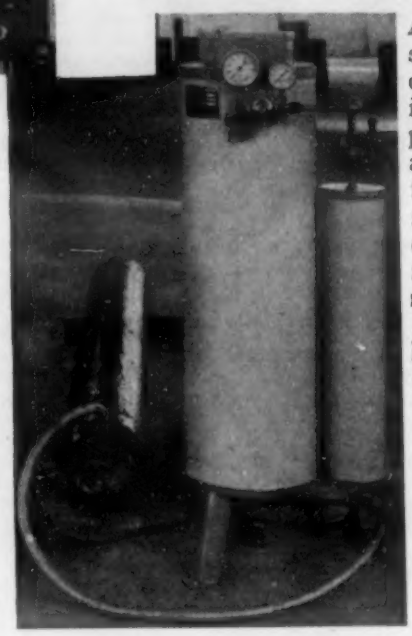
It had been found that the hardness of Fe is greatly increased, similarly to duralumin, if it is quenched below the A_1 temperature and subsequently stored at room temperature; this phenomenon is called precipitation hardening as the name "refining" as used for duralumin means an actual improvement in mechanical properties while in the case of Fe a decrease of notch-toughness, elongation and reduction of area takes place. The precipitation hardening is ascribed to some substance of highly dispersed segregation in the molten metal and takes place if the solubility of this substance decreases with falling temperature, as the amount absorbed at higher temperatures is retained in quenching; that is, the alloy must be able to undercool and if the substance precipitates in storing at room temperature in an amount equivalent to the equilibrium. On the basis of the binary diagrams it was expected that O and N can have this effect. Tests showed that with increasing O only a weak increase of the precipitation hardening is observed except at a critical amount of 0.06%. On the other hand, N causes a very decided increase of the precipitation hardening at contents above 0.015%. Ha (10f)

Precipitation Hardening of Silicon-Nickel Alloys. (Ausscheidungshärtung bei Silizium-Nickel-Legierungen.) O. DAHL & N. SCHWARTZ. *Metallwirtschaft*, Vol. 11, May 13, 1932, pages 277-279.



5 references. Alloys of Ni and Si were chill cast, heated to 950° C. for 4 hours and half the test bars were furnace cooled, the other half quenched in water. The best bars were then reheated to temperatures up to 900° C. and hardness and electrical resistance measurements were made.

Alloy	Brinell Hardness in kg./mm.² After annealing at 950° C. and quenching	Maximum hardness after reheating	Increase %
95.4% Ni, 4.6% Si	141	152	8
94.4% Ni, 5.6% Si	139	284	104
93.4% Ni, 6.6% Si	160	383	139
92.4% Ni, 7.6% Si	208	392	88
91.4% Ni, 8.6% Si	300	417	39



The maximum hardness, which is obtained by reheating to 600° to 650° C., is practically independent of the rate of cooling after annealing. The electrical resistance first increases, reaching a maximum at about 500°, then a minimum at 650°-700° C., then increasing again. This is similar to the action of duralumin. The precipitation hardening progresses very slowly. Similar results were obtained with alloys of 75% Ni and 25% Fe with Si additions. Some corrections are suggested for the constitutional diagram of Ni and Si according to Guertler and Tammann. CEM (10f)

Welding & Cutting (11c)

American Rules on Fusion Welding of Boilers and Pressure Vessels. (Amerikanische Vorschriften für Schmelzschweissung an Dampfkesseln und Druckgefässen.) F. W. RÜDEL. *Archiv für Wärmewirtschaft und Dampfkesselwesen*, Vol. 13, Apr. 1932, pages 99-103.

Survey and discussion of the most important rules of the new A.S.M.E. boiler code on fusion welding on steam boilers and unfired pressure vessels. Mechanical testing, radiography, supervision of welders, rules on annealing, water pressure tests. 8 references. GN (11c)

Welding Experiments. (Schweisstechnische Versuche.) FRANZ KRYNES. *Zeitschrift des Österreichischen Ingenieur-und Architektenvereins*, Vol. 84, July 29, 1932, pages 157-158.

Résumé of papers before the Society of Mechanical Engineers at Vienna: F. Regler: Spannungen in technischen Werkstücken und ihr röntgenographischer Nachweis. F. Leitner: Schweissen von rost- säure- und hitzebeständigen Stählen. GN (11c)

Treatise on the Entire Field of Welding Technique. (Darstellung der Gesamten Schweisstechnik.) P. BARDTKE. VDI Verlag, Berlin, 1931. Cloth, 6x8 inches, 275 pages. Price 12.50 RM.

The second edition of this volume on the entire field of welding technique (including cutting) treats in a concise, lucid manner all the different methods now employed in fusion-, pressure- and aluminothermic welding. Each method is explained in its principles and well illustrated by diagrammatic figures showing wrong and correct procedure and giving a full description of the required apparatus. Steel and iron take up, of course, the greater part of the book, but the other industrially important metals are just as fully treated. The metallurgical conditions, the equilibrium diagram and chemical reactions are discussed insofar as is required for the proper understanding of the welding mechanism. A very good chapter deals with the economics of welding compared with riveting and with the calculation of the various items making up the total cost. The testing methods, destructive and non-destructive, are aptly treated, and the X-ray technique justly given the place it has won in present-day practice. But as the book is published as late as 1931 one could have expected to see also mentioned the testing with gamma-rays, that is by radium or radioactive materials, which has certain pronounced advantages over the X-ray method as recent publications on the subject have pointed out. This minor omission, however, does not detract from the value of the book, which is rather enhanced by a valuable contribution on the safety measures to be observed in welding. Although written mainly from and for the German standpoint the practice of other countries, especially of the U. S. A., is not neglected and makes it valuable also for readers of this country.

Welded Metal Construction in Civil and Industrial Construction. (Sull' impiego delle strutture metalliche saldate nelle costruzione civile e industriale.) G. Accati. *La Metallurgia Italiana*, Vol. 24, July 1932, pages 573-579.

The advantages of welding in steel construction are discussed. AWC (11c)

A New Process for Making Welded Joints. H. S. George. *Journal American Welding Society*, Vol. 11, July 1932, pages 22-28.

Paper presented at the Annual Meeting of the American Welding Society, New York, Apr. 1932. A description of the recently developed welding process known as "Linde-welding," an oxyacetylene process using an excess of acetylene which causes the formation of a carbonaceous film as a flux to enable the filler metal to unite with the base metal. Advantages are high speed of welding, economy and excellent weld quality. TEJ (11c)

Welding of Iron under Pressure. (Ueber die Press-Schweissbarkeit des Eisens.) Hans Esser. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen*, Vol. 11, 1932, 8 pages.

The methods and apparatus are described which were used for the determination of the correlation of the pressure-weldability (as against fusion weldability) of pure Fe and pure Fe-C alloys with temperature, welding pressure, surface quality and grain size. The tests were made in a vacuum. See *Metals & Alloys*, Vol. 2, Apr. 1931, page 83. Ha (11c)

Combined Effect of Riveting and Welding in Tension and Compression. (Zusammenwirken von Nietung und Schweissung bei Zug und Druck.) G. Gaber. *Der Bauingenieur*, Vol. 13, May 20, 1932, pages 290-294.

Experiments show that riveted constructions are economically reinforced by welding. The riveted construction must be reinforced in stressed state. When in a tensile test bar under an initial stress of ½ actual load the shearing surface of the sole rivet is increased by 82% by 4 additional welds, the bearing power of the bar is increased by 67%. According to the calculation the bearing power of the welds becomes effective to 57%. At the breaking load the rivet participates only to 50% of its bearing load, the seams, however, to 100%. When in a compression test bar under an initial load of ½ actual load the shearing surface of the 4 rivets is increased by 82% by 8 side welds, the bearing power is increased by 73%. The calculation shows the bearing power of the welds to become effective to 81%. At the breaking load the rivets actually participate to 83%, the welds to 100%. The combined effect of rivet and weld, therefore, is better when several rivets are present. In suitably adjusting the welds to the rivets, riveted constructions can economically be reinforced by welding while construction is in use. GN (11c)

Welded Lattice Crane Girder. V. A. Prince. *Welder*, Vol. 3, June 1932, pages 6-19.

The particular points to be observed in the building of crane girders by welding are illustrated and treated in detail in a complete calculation of a bridge girder for a 25-ton overhead traveling crane of 72-ft. span. All construction details are given. Ha (11c)

The Endurance Strength of Fusion Welded Steel Sheets. (Die Dauerfestigkeit von autogengeschweissten Stahlblechen.) F. Pester & Hans Schulz. *Die Schmelzschweissung*, Vol. 9, June 1932, pages 130-132.

The tensile properties of steel sheets, right-hand and left-hand welded and hammered and not hammered, were investigated and compared with those of the unwelded material. In general, the values of tensile strength, elastic limit, ultimate strength and endurance bending strength are reduced; right-hand welds show a greater ultimate strength than left-hand welds. Hammering of the red-hot seam increases the endurance strength about 10% for left-hand welds and 20% for right-hand welds. The testing method is described in detail. Ha (11c)

Study of the Employment of Arc-Welding in Naval Construction: The Problem of Welded Joints. (Essai sur l'emploi de la soudure a l'arc en construction navale: le probleme des joints soudes.) J. Pinczon. *Revue Generale de l'Electricite*, Vol. 31, June 11, 1932, pages 807-814.

The value of arc-welding in the construction of vessels is discussed and the forces in the welds analyzed. According to the author it will suffice for arc-welding of the parts of a ship to determine the characteristics of a riveted assembling which would have to be used. Instead of lap-welding, butt-welding with V-shaped ends is recommended which in certain cases is the only practical method. Instead of using a discontinuous double-fillet it is better to employ in all cases a continuous fillet of half the height of the thickness of the sheet or profile. The author warns against insufficiently tested innovations, as in ship construction safety must be the first consideration. Ha (11c)

The Art of Welding—A Nontechnical Résumé. D. E. King. *Steel*, Vol. 90, Mar. 28, 1932, pages 38-39.

The author describes a series of 4 ingenious experiments with lighted candles to demonstrate the principles of various types of welds. The requirements for a good weld are cleanliness, control of applied heat, control of pressure, and control of the structure of deposited metals. JN (11c)

Effect of Phosphorus on Welding Properties of Mild Steel. Roger Powell. *Welding*, Vol. 3, Aug. 1932, pages 469-470.

In forge-welding high C to mild steel, best results are obtained when the mild steel is Bessemer stock containing .08-.12% P. TEJ (11c)

Conclusions and Results of Electric Welding. (Erkenntnisse und Erfolge bei der elektrischen Schweissung.) Willy Prox. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, May 21, 1932, pages 497-504.

The great progress made in the production of high-quality materials made necessary also a method for joining these metals; the advantages and defects of electric welding and its testing methods are briefly discussed. Ha (11c)

Electrically Welded Steel Frame Masts. (Elektrisch geschweisste Stahlgittermaste.) Klee. *Elektroschweissung*, Vol. 3, July 1932, pages 135-136.

Outline of the procedure to be followed. GN (11c)

Significance and Recognition of Initial Stresses in Welded Constructions. (Zur Frage der Bedeutung und Erkennung von Anfangsspannungen in geschweissten Konstruktionen.) O. Bierett. *Stahlbau*, Supplement to *Bautechnik*, Vol. 5, June 10, 1932, pages 94-96.

1 The paper discusses the relation between the changes of shape of base metal and joint in welded constructions at which the stresses in the seam, particularly the normal stresses, depend on the behavior of the base metal during welding. The possibilities of recognizing the initial stresses in the cooled seam are considered. The author shows that there has not yet been devised a method which, in order to determine the stresses, permits measuring the changes of shape during welding of the seam or at least near the seam and which sufficiently takes account of the temperature effects. The Heyn and Bauer method for stress determination is too complicated. On the basis of loading tests on welded

2 constructions the author made observations which led him to a simple method which permits drawing conclusions upon the initial stresses in the welded construction. By plotting load-deformation curves the curves were found to show characteristic deviations from the straight line deformation to be expected. These deviations were used to determine the initial stresses. From such test conclusions it is also possible to determine the most favorable welding conditions with respect to the initial stresses. 3 references. GN (11c)

The Fusion Weldability of Austenitic Manganese Hard Steel. (Die autogene Verschweissbarkeit von austenitischen Manganhartstahl.) H. Buchholz. *Die Schmelzschweissung*, Vol. 9, June 1932, pages 122-127.

3 A successful welding of austenitic Mn steel is possible with observation of several factors: the excess of gas should be so that the blue gas cone in the flame is about 1-1½ times as big as the flame cone; to obtain an absolutely thorough weld a flux should be employed as protection against oxidation by air on the underside of the sheets. The burner should be for a larger size of sheet than that to be welded. The welding process for this kind of steel

4 should be carried out fairly slowly. The right-hand (progressing) welding is superior to the left-hand (retrogressive) welding as the oxides are driven away from the fusion by the pressure of the flame gases and the weld is dense and homogeneous. X-seams should be avoided, and the process should not be interrupted. Hammering when still warm is to be avoided as cracks may occur. Ha (11c)

Welding in Steel Structural Work—British Practice. James Caldwell. *Welding Journal*, Vol. 29, June 1932, pages 166-169.

Paper read before the International Association of Bridge and Structural Engineering, Paris Congress, May, 1932.

5 Electric arc welding of steel structures has developed into general practice. The heavy coated electrode is generally used, the light single-run fillet weld being preferred. Allowable working stresses are: Tension, 8.0 tons/in.²; Compression, 6.5 tons/in.². The main factors controlling economic and consistent welded production include intelligent design, sound organization and welding procedure, thoroughly trained operators and inspectors and the employment of correct welding equipment and electrodes. Much work has been done in strengthening of steel structures by welding, though it is generally agreed that a combination

6 of riveting and welding in the same structure is bad practice. TEJ (11c)

Sixty 8-inch Pipe Welds per Hour. Malcolm Clark. *Welding Engineer*, Vol. 17, Jan. 1932, pages 29-31.

The details of the construction of an automatic pipe welder for butt-welding 8″ pipes in the field are described. The transformer can give 1200, 800 and 600 kva. at 4 different secondary voltages. The upset pressure of 1200 lbs./in.² is given by 2 hydraulic cylinders and totals 188,000 lbs. The time cycle of the weld can be adjusted from 4-40 seconds. The actual welding time varies from 4½ sec. for

7 3½″ pipe to 22 sec. for 16″ pipe. Ha (11c)

Gas and Electrically Welded Tubes. (Autogen und elektrisch geschweisste Rohre.) Köster. *Gas und Wasserfach*, Vol. 75, June 11, 1932, pages 498-499.

Microscopic examinations and mechanical tests on welded pipes installed at the Berlin Water Works during the year 1931. GN (11c)

Machine Welding—Problems in Design and Operations. J. L. Anderson. *Journal American Welding Society*, Vol. 11, June 1932, pages 7-9.

8 Paper presented at the annual meeting of the American Welding Society in New York, Apr. 1932. Change from manual to mechanical gas welding cannot be satisfactorily made until every variable is removed or controlled. The author discusses the variables encountered, particularly weldability of steel, and warpage due to welding heat. Warpage is controlled by mechanical means as well as through the application of heat at various points other than the welding zone. TEJ (11c)

Resistance Welding in Europe. M. L. Eckman. *Welding Engineer*, Vol. 17, Jan. 1932, page 46.

9 Impressions of the art in Germany, England, France and Italy. A greater development of alternating current arc welding was noticed. Ha (11c)

The Application of Welding Technique in Constructing Boilers and Vessels and in Repair Work. (Die Anwendung der Schweisstechnik beim Bau von Dampfkesseln, Behältern und bei der Ausführung von Reparaturen.) F. A. Birke. *Apparatebau*, Vol. 44, Apr. 29, 1932, pages 67-72.

10 The article first considers the advantages which welding offers in boiler construction in comparison with riveting. It could be proven that whenever welded boilers exploded this was due to a faulty welding practice. In Germany there is not yet a uniform regulation as to the licensing of firms that are doing welding work. The paper then shows in some interesting examples to what extent it is possible today to successfully repair boilers or chemical vessels by welding. GN (11c)

The Gas and Electric-Welding of Acid-proof Steel. (Das autogene und elektrische Schweissen säurefesten Stahls.) *Die Metallbörse,* Vol. 22, Feb. 13, 1932, pages 194-195.

The writer points out the difficulties encountered in welding stainless steels, i.e. (1) volatilization of Cr and oxidation of Ni at high welding temperatures, (2) carbon absorption of stainless steels low in C, (3) low heat conductivity of the Cr steel sheets, (4) extremely large heat expansion of the sheets exceeding 50% that of ordinary steels. Data are presented with regard to electro-welding. The arc should not be too long and the welding rods should contain 19% Cr, 8.5% Ni and below 0.10% C. The advantage of gas welding, i. e. the low welding temperature is nullified by the C content of the torch, which induces C into the steel. The torch should be neutral or slightly reducing. However the C content of the seam is very likely to run up as high as 0.5-0.6% C. Neither welding method can eliminate the drawback mentioned under (3). A slight advantage is claimed by the author for the oxy-acetylene welding method. Cooling devices should be provided for. In order to prevent warping due to (4) the sheets should be clamped rigidly. The welding operation should be followed by an annealing treatment to nullify structural changes occurring during the welding performance. EF (11c)

Economies obtainable by Welding in Structural Fabrication. Alex. L. Wilson. *Welding Engineer,* Vol. 17, Mar. 1932, pages 43-45.

The points which would recommend welding instead of riveting of structures are discussed. Welding offers 3 advantages in design: (1) in tension members no deduction need be made for holes, (2) connecting members are eliminated and (3) non-working areas are eliminated. The shop costs entering the question of possible economies are discussed; semi-automatic welding machines are recommended. Ha (11c)

Welding Standards in the Piping Industry. John Zink. *Industry & Welding,* Vol. 3, June 1932, pages 3-6, 31-32.

The practical points of welding neck flanges, van Stone flanges and slip-over flanges are discussed. Fittings should be made from seamless tubing, elbows should have a radius of 1½ times the pipe diameter under proper consideration of pressure drop, appearance, standardization, etc., and uniform and full wall thickness to line up true with the pipe or flange to which it is to be welded. The ends of all fittings should be beveled in accordance with the National Association Standards. Short tangents are not necessary but are permissible. Ha (11c)

Homemade Spot-Welding Machine. *Engineering & Mining Journal,* Vol. 133, Aug. 1932, page 421.

A photograph and a brief description are given of an automatic welding machine made for the Homestake Mining Co. The machine is applicable for welding mine ventilating pipe. The operation of spot-welding 12" galvanized Fe piping is illustrated. WHB (11c)

Use and Construction of Staybolt Welded Structures for Equipment Construction. (Anwendungen und Ausführungen von Stehbolzenschweissverbindungen in Apparatebau.) Wittmann. *Die Chemische Fabrik,* May 11, 1932, pages 150-151.

Describes the construction of cooling and heating units and heat exchangers, making use of the double wall design and staybolt welding. CEM (11c)

Welded Fractionating Columns. *Industrial Chemist,* Vol. 8, Mar. 1932, page 118.

A brief note on the construction of 2 welded fractionating columns weighing 26 tons each. RAW (11c)

Pediatric Building for the Boston City Hospital, Shop and Field Welded. J. Theodore Whitney. *Journal American Welding Society,* Vol. 11, July 1932, pages 20-22.

Factors on which the Hardness of Built-up Welds Depends. (Faktoren von denen die Härte von Auftragsschweissungen abhängt.) K. L. Zeyen. *Die Schmelzschweissung,* Vol. 11, June 1932, pages 117-120.

Tests made with different welding wires have shown that the Brinell hardness of the seam depends greatly on the burning of alloying elements out of the welding wire as also on the manner of welding, and secondly on the cooling velocity of the weld, the welding method, thickness of the material and number of seams laid on top of each other. Besides, the chemical composition of wire and base material is very important. The hardness of the seams increases for single seams by electric arc welding with increasing thickness of the base material, but decreases by the fusion welding method. For several layers of seams the hardness is less if one seam is still warm when the next is put on. The hardness is less influenced if the welding wire contains Cr and V than if C only is contained in the wire. Ha (11c)

Oxy-Acetylene Welding and Cutting in Coal Mines. E. S. Wade. *Mining Congress Journal,* Vol. 18, July 1932, pages 37-38.

Numerous examples are cited of the uses to which oxy-acetylene welding and cutting torches can be put in coal mines. This equipment is most important means for making savings in labor and materials, and for increasing operating efficiency in every phase of mining. DTR (11c)

Quality of Welds may be Determined by Visual Inspection. Frank B. Walker. *Transit Journal,* Vol. 76, July 1932, pages 309-311.

Visible criteria of a good weld include the following: no drops spattered nearby, no overlap (incomplete fusion at weld edges), both edges merge smoothly into base metal, uniform bright luster, uniform size and thickness. Unsatisfactory welds can be attributed to the arc being too long or the arc being too hot or cold. Paint, scale, rust, dirt, oil prevent good welding. CBJ (11c)

Welding of Steel Structures. (Vasszerkezetelk hegesztése.) K. Rotter. *Anyagvizsgalok Közlönye,* Nov.-Dec. 1930, pages 136-150.

Remarks on the problem of welding steel structures, which gain an always growing field of application in America as well as in Europe. The latest German regulations for welding steel structures above ground are discussed, some examples of welding in bridge buildings are shown. The questions still unsolved in this line are pointed out. GG (11c)

Course for Teaching Pipe Welding in a Trade School. C. H. Britton. *Welding,* Vol. 3, July 1932, pages 435-438.

As a result of 4 years' experience in teaching pipe welding, a course has been outlined which if carefully carried through by the student will result in his becoming a good welder. Outline of the course is given. TEJ (11c)

Automatic Arc Welding with the Shielded Arc. A. F. Davis. *Machinery,* Vol. 38, Jan. 1932, page 369.

Discussion of "Automatic Arc-Welding Applications" published in *Machinery,* Dec. 1931, page 270. Molten weld metal while being deposited has an affinity for O and N. A method of shielding the weld metal has been devised. This is said to completely shield the weld metal from the O and N, and so increase the strength of the weld and reduce the possibilities of corrosion. RHP (11c)

Arc Welding Helps Save $1,000,000 on Boston Tunnel. A. F. Davis. *Journal American Welding Society,* Vol. 11, June 1932, pages 15-16.

Description of tunnel under Boston Harbor, in the construction of which arc welding played an important part. The steel liner is made up of rings, 31 ft. in diameter and 2½ ft. wide, each ring containing 11 segments or panels. There are 132.72 miles of welding which was done with the shielded arc process. TEJ (11c)

On the Testing of Welded Joints by Milling or X-rays. (Über die Prüfung von Schweissverbindungen durch Anfräsen oder Röntgenstrahlen.) R. Bernhard & A. Matting. *Stahlbau,* Vol. 5, July 22, 1932, pages 114-116.

Experiments show that welded joints can be examined in simple cases by milling and etching. This holds true, for instance, for building constructions, when detrimental effects due to minor or no dynamic loads need not be feared. Milling may then be used as supplement to X-ray examinations. For constructions which, for reasons of safety, need careful examination, X-raying cannot be dispensed with. Due to its manifold application, X-ray equipment can be utilized economically. 7 references. GN (11c)

75 Miles of Welded Piping in New Hospital Unit. *Steel,* Vol. 90, Mar. 21, 1932, pages 34-35.

The new group of buildings for the New York Hospital —Cornell Medical Clinic in New York utilized 60,000" of acetylene gas welding in the construction of its pipe lines for heating, power, refrigeration and ventilation. This $2,000,000 welding contract required 75 miles of steel and wrought Fe pipe, ranging in diameter from 2½ to 24" and weighing a total of 750 tons. Fabrication included loops, sharp turns, curves, cross-overs, underground tunnels and sub-basement work. JN (11c)

Corrosion-Resisting Steel Milk Truck Tank Withstands Price War Bombing. *Steel,* Vol. 90, Apr. 4, 1932, page 43.

A welded corrosion-resistant steel tank loaded with 2000 gal. of milk successfully resisted rupture when a violent explosion of dynamite occurred at its rear end. The force of the explosion dented the tank, damaged the Al and cork coverings considerably, and blew off the manhole cover. JN (11c)

Difficulties in Electrically Welding Copper. (Schwierigkeiten beim elektrischen Schweissen von Kupfer.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, July 3, 1932, page 355.

Brief discussion of the detrimental effect of oxygen and porosity on the tensile properties of Cu. GN (11c)

Control of Expansion in Copper Plate Welding. *Welding Engineer,* Vol. 17, June 1932, pages 37-38, 44-45.

The method of welding big Cu vats 6 ft. 4 in. in diameter and 8 ft. 6 in. in height is described in full. (11c)

Controlling Expansion and Contraction. *Welding News,* Vol. 3, Apr.-June, 1932, pages 17-19.

The proper handling of material for the elimination of the effects of expansion and contracting during welding is discussed and practical suggestions made so that when the weld is finished and the metal has finally cooled, it will have attained its original shape internally as well as externally, and there will be no internal stresses. Ha (11c)

Recently Welded Bridges. (Neuere geschweisste Brücken.) *Schweizerische Bauzeitung,* Vol. 99, Jan. 16, 1932, pages 35-36.

Description of construction and welding of the Rhone bridge near Leuk, Switzerland, and of a bridge in the Skoda plant at Pilsen, Czecho-Slovakia. GN (11c)

Mild Steel Welds Deposited with the Electric Arc. The Role of the Coating from the Point of View of Distortions of the Crystalline Grains. (Sur les soudures en acier doux déposées à l' arc electrique. Róle de l' enrobage au point de vue des distorsions des grains cristallins.) D. Rosenthal & M. Mathieu. *Comptes Rendus,* Vol. 194, Apr. 11, 1932, pages 1244, 1245.

The authors have already shown *Comptes Rendus,* Vol. 191, 1930, page 484, by means of X-rays the existence of distorted grains in welds made with bare electrodes of mild steel. In welds which have been protected by slag, or made with coated electrodes, scarcely any such distorted grains occur. The present paper deals with results of tests which serve to confirm their previous observations. These show that the absence of distortion in welds made with coated electrodes is due to annealing of the welds *in situ.* This annealing occurs more easily when *at the same time* the coating affords protection to the weld against oxidation and nitridation. OWE (11c)

Testing of Weld Seams on the Electrically Welded Schlachthof Bridge in Dresden. (Schweissnahtprüfungen an der elektrisch geschweissten Schlachthofbrücke in Dresden.) F. Reinhold. *Elektroschweissung,* Vol. 3, July 1932, pages 128-131.

The testing of the seams was performed according to the Schmuckler method. The milled seam was etched with a saturated solution of Cu-ammonium chloride. A special method is suggested in which the quality of the seam at every milled spot is characterized by a quality number. For every welder there is obtained a series of quality numbers from which the mean quality number and the degree of uniformity of the performance of every welder is to be determined. A better judgment and supervision of the work of every welder is thus achieved. The latter procedure is to be replaced by continuous mechanical tests of the seams after the relation between quality number and tensile strength of the seam has been established. GN (11c)

Application of the "Schlierenmethod" for the Examination of Cutting Nozzles. (Anwendung des Schlierenverfahrens zur Untersuchung von Schneiddüsen.) MAIER. *Autogene Metallbearbeitung,* Vol. 25, June 1, 1932, pages 170-171.

The "Schlieren" method is an optical method for the examination of gases which escape from a nozzle under high pressure and has the advantage that the gas jet is not disturbed by the insertion of measuring instruments. The principle of the method is that the escaping jet is illuminated by a pointed light source and makes visible optical differences of density between the gas and the surrounding atmosphere. The picture of the gas jet is projected to a screen. At a certain pressure stationary waves are formed in the jet and from the picture the influence of the shape of the nozzle can be determined. A few photographs illustrate the method. Ha (11c)

Resistance Welding in the Dodge Automobile Plant. JAMES J. MURRAY. *Welding,* Vol. 3, July 1932, pages 411-413.

Description of flash, projection and arc welding operations in an automobile plant. TEJ (11c)

Developments in Fusion Welding. T. S. MURPHY, JR. *Welding Engineer,* Vol. 17, May 1932, pages 33-36; June 1932, pages 41-43.

The particular suitability of fusion welding in the manufacture of pressure vessels is pointed out; the improvements in the processes and testing methods are described. Ha(11c)

Electric Arc Welding Instead of Water Gas Welding. (Lichtbogenschweissung statt Wassergasschweissung.) C. MASSMANN. *Elektroschweissung,* Vol. 3, May 1932, pages 96-98.

Up to the present time boilers, high pressure vessels and similar apparatus are still water gas welded in general. More recent experience, however, shows that such apparatus which have to meet highest requirements can successfully be welded electrically, provided suitable electrodes are applied. Despite the high expenses for electrodes electric welding is 40-60% cheaper than water gas welding. The paper summarizes the results of mechanical tests on welded plates (plate thickness : 15 mm, weld : V-shaped with an angle of 60°). The results of tensile tests, bending tests, bending tests after quenching, notch toughness tests and aging tests proved the welds of highest quality. On the base of these results the author suggests that electrically welded joints should be admitted with a calculation factor of 0.9 as it is used for water gas welded joints. Testing, naturally, is to be performed along the same principles as used for testing water gas welded apparatus. GN (11c)

Continuous Manufacture of Welded Conduit. J. B. NEALEY. *Steel,* Vol. 90, Feb. 8, 1932, pages 31-33.

A description of the continuous process in use by the Fretz-Moon Tube Co. of Butler, Pa., for the continuous production of steel conduit from coiled skelp. JN (11c)

Bending Tests on Welds. (Über Biegeversuche mit Schweissungen). O. MIES. *Elektroschweissung,* Vol. 2, Sept. 1931, pages 170-176.

The significance of the testing values obtained in bending tests, as angle of bending, Tetmajer bending value and the elongation of bending, on non-welded and welded sections are considered. The difference between the capacity of deformation of the welded joint and the base metal is pointed out. The angle of bending as determined by the transverse bending test is indicative of the transverse bending capacity of the joint but not indicative of the capacity of deformation of the joint, including the base metal. The capacity of deformation of the joint is better determined by longitudinal bending tests which simultaneously characterize the longitudinal bending capacity of the joint. The question is raised whether or not the determination of the longitudinal bending capacity is of the same importance as the transverse bending capacity which is generally determined. It is pointed out that both of these tests bring about no new knowledge on the properties of the weld in comparison with the longitudinal and the transverse pulling test. GN (11c)

Welding Non-Magnetic Steel Alloys. PAUL ORR. *Machinery,* Vol. 38, Mar. 1932, pages 489-491.

Tops of oil circuit breaker tanks are made of non-magnetic metal. These have the following composition: C, 0.25 to 0.40 %; Mn, 6 to 8%; and Ni, 10 to 12%. The strength and physical characteristics of this is similar to and slightly better than mild steel. Describes the welding procedure in considerable detail. RHP (11c)

Qualifying the Welding Wire. G. W. PLINKE. *Welding Engineer,* Vol. 17, Mar. 1932, pages 27-31.

The qualities of welding wires are discussed and the mechanical properties of a few types for welding mild steels and ferrous and non-ferrous alloys described. The advantage of exclusion of harmful atmospheric contamination in welding is explained and its elimination by producing a protective atmosphere in oxy-acetylene welding and the atomic hydrogen process described. Ha (11c)

Arc Welding Hazards—Their Cause, Effect and Prevention. F. S. PEASLEY. *Welding,* Vol. 3, July 1932, pages 418-421.

Common hazards peculiar to arc welding are (1) Use of improper goggles, garments, shields or devices for protecting the operator and other workmen, (2) Insufficient or no ventilation of booths or rooms to exhaust smoke, fumes and gases, (3) Failure to indicate or mark hot metal or stock, (4) Insufficient training and instruction of operators in the technique of welding and use of precautionary measures and protective devices. TEJ (11c)

On the Stress Distribution in Front Butt Weld Seams. (Über die Spannungsverteilung in Stirnkehlnähten.) OTTO MIES. *Elektroschweissung,* Vol. 3, Aug. 1932, pages 141-147.

The stress distribution in front seams is treated, taking into consideration the conditions of equilibrium and deformation. From the testing results it is concluded that an approx. linear stress distribution can be assumed for the cross-sections through the corner of the seam. The stresses in the corner are higher by a certain amount than the mean stress. Taking into consideration the stress distribution and the amount of the molten welding material the most favorable form of the seam is calculated. 3 references. GN (11c)

Electrical Double-Spot Welding. (Die elektrische Doppelpunktschweissung.) K. RUPPIN. *Elektrowärme,* Vol. 2, June 1, 1932, pages 137-138.

1 This new process consists in the following: If a thin sheet is to be welded to a thicker one the 2 electrodes are used to make contact at first with the thin sheet and heat up and soften it so that the pressure between the 2 pieces brings them into intimate contact; the current flows now also through the thick sheet and the actual welding is done. This method has the advantage over the usual process where the contact is made in a single spot as the electrodes are connected each to one sheet instead of both to the same sheet, so that the size of the pieces welded together is irrelevant, and even not fully cleaned surfaces can be welded as the heat developed in the one sheet first burns the dirt, grease, etc. and cleans the spot to be welded. It is further claimed that it is more time saving as 2 points are 2 welded simultaneously where formerly only one was finished. It is more convenient to handle and can be moved more easily. The process is particularly useful in the making of automobile bodies, locomotive construction, metal furniture, etc. Ha (11c)

Oxyacetylene Welding in Production. H. O. T. RIDLON. *Journal American Welding Society,* Vol. 11, July 1932, pages 18-20.

Abstract of paper presented at March 4th 1932 Meeting of Chicago Section of American Welding Society. The 3 principal factors in connection with production welding and cutting are (1) proper use of equipment, (2) production 3 methods and use of jigs, (3) the operator or the human element. TEJ (11c)

"Shot Welding" Stainless Steel in Aircraft Construction. E. J. W. RAGSDALE. *Welding,* Vol. 3, Aug. 1932, pages 471-473.

Paper read before the American Society of Mechanical Engineers at Buffalo, New York. A discussion of the uses of stainless steel of the 18 and 8 type in aircraft construction with particular reference to welding this material. Shot welding is a spot welding operation done at high currents and short time of current dwell. It is the only known method of welding 18 and 8 without causing carbide precipitation. TEJ (11c)

4 **Further Development of the Arcatom Welding Method. (Weiterentwicklung des Arcatom-Schweissverfahrens.)** S. SANDELOWSKY. *A E G-Mitteilungen,* Mar. 1932, pages 112-114.

Recent improvements in regard to operation, application and service with some results are described. Ha (11c)

On Stresses in Welded Wheel Tires. (Über Spannungen in auftraggeschweissten Bandagenradsätzen.) S. SANDELOWSKY. *Elektroschweissung,* Vol. 3, July 1932, pages 121-127.

The paper first discusses origin and size of thermal stresses set up by temperature changes for the simple case of a bar. The temperature course in welded wheel tires was 5 studied. (Wheel: open hearth steel, rim: cast steel, welding speed 10 m/hr.). On welding the temperature increases expotentially and reaches a maximum after half of the total welding time. The hub is heated up more slowly. The shrinkage and welding stresses were determined separately. The welding stresses decrease with increasing C content. Welding rods with .8-1.0% C should be used, so that the C content of the seam amounts to at least .5%. For equal chemical composition of the seam the temperatures of seam and base metal chiefly affect the originating stresses. The wheel set should be welded as hot as possible, but at temperatures above 180° C. of the parts to be welded together the 6 weld obtained is not reliable. Under normal conditions the welding stresses amount to from 28,500-56,900 lbs./in^2. The total stresses set up varied between 62,600-132,300 lbs./in^2. 4 references. GN (11c)

Welding in the Assembly Plant. (Schweissen im Fertigungsbetrieb.) SCHAUBERT. *Maschinenbau,* Vol. 11, Jan. 7, 1932, pages 17-18.

Paper read before the Arbeitsgemeinschaft deutscher Betriebsingenieure, Cologne, 1931. A comprehensive account of the latest progress in welding as seen from the designers' and mechanics' viewpoint. RV (11c)

7 **Arc-Welding in Metal-Carpentering. (La Soudure a l'Arc dans la Menniserie Metallique.)** R. SARAZIN. *L'Usine,* Vol. 41, Apr. 29, 1932, pages 31-35.

Describes and illustrates methods used for joining small metallic parts, as window sills, sashes, ornaments, etc. which have to be built up from structural shapes. Ha (11c)

Riveting (11d)

Gasholder and Tank Riveted Joints. S. M. MILBOURNE. *Gas Journal,* Vol. 198, May 25, 1932, pages 436-438.

8 Describes a graphical method of analysis which facilitates the design of most forms of riveted joints and enables the efficiency to be readily estimated without tedious calculation. MAB (11d)

Rivet Manufacture Keeps Step with Progress in Fabricating Methods. PIERRE CHAMPION. *Steel,* Vol. 90, Feb. 8, 1932, page 35.

The demands of higher strength steels have been met by the development of rivets having higher strengths and better physical properties. A recent development is a special processed hot-formed rivet made of forging steel for boiler construction. The use of cold pressed, annealed rivets 9 is increasing with the use of electric rivet heaters. Stainless steel rivets have been introduced for use in ship bottoms. JN (11d)

Tests with Riveted Joints under often Repeated Load. (Versuche mit Nietverbindungen bei oftmals widerholter Belastung.) OTTO GRAF. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 76, Apr. 30, 1932, pages 438-442.

A series of tests was made to find out if there is any advantage in using the modern special building steels compared with ordinary steel when they are subjected to greatly varying, often repeated stresses. In dimensioning of rivets and rivet joints special precaution must be taken 10 in obtaining as high as possible a gliding resistance; deformations or dislocations even under low loads are permanent, and subject the rivets to stresses which can not be equalized by spring action of the metal. The rather complicated conditions are shown in photographs and curves. Ha (11d)

Modern Trends in Open-Hearth Operations. L. F. REINARTZ. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 51-53, 55. 4

To supply hot metal for the open-hearth some blast furnace operators are experimenting with the production of pig-Fe by reduced blast or by intermittent operation of the stack. For balancing operating rates between the open-hearth department and the mills, most plants have found it best to shut down excess furnaces and run a minimum number straight through the week. Various methods have been tried to prevent deterioration of furnace bottoms, such as filling the hearth with coke-breeze before the bottom has dropped below 500° F., or painting it with tar after it had reached room temperature. Several plants have insulated their bottoms with 2½" of insulating brick or cement, such layer having the same thermal conductivity as 4 courses of clay brick. Tabulates the thermal conductivity of different bottom materials in B.t.u./ft.²/in. thickness/1° F./hr. Combustion control continues to hold main interest. Tendency, however, has been to do those things which can be dene without purchase of expensive control equipment. Many plants have changed from producer gas to coke-oven or blast-furnace gases, fuel oil, or tar. Furnaces of 150 ton capacity have become well established. Use of 2 stopper rods in a ladle has helped some plants improve quality. Silica brick or high alumina brick has been used on the top courses of checker chambers, and a second quality brick in the lower courses. Experimental work is being conducted on a small scale open-hearth furnace equipped with oil burners, utilizing the principle of rapid heat transfer by direct contact of the flame with the bath. Herty has continued his work on inclusions. Much work remains to be done on effect of mold analysis and design on quality. 5 6

Practical hints. GN (12a)

Open-Hearth Metallurgy in 1931. C. H. HERTY, JR. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 49-50.

Review of American developments during the year. Trend is toward furnaces averaging 150 tons capacity. Use of the mixer-type transfer ladle is growing. There is considerable possibility of making real progress toward S elimination in this type. Changing of fuel on a given furnace has given operators a great deal of trouble. A number of plants are experimenting with 2 and 3 pass checkers. Insulation of furnaces has been stressed. Alloy contamination of plain C open-hearth steel is under investigation. During the winter months of 1931, average alloy contamination of 24 plants was: Cr, 0.017%; V, 0.005%; Ni, 0.039%; Cu, 0.086%, and Sn, 0.005%. Average residual Mn was 0.18%. Many plants are controlling slag by making a quick determination of FeO in a given volume of crushed slag and regulating their additions or working their heats according to the results of the determination. New deoxidizers are being developed rather slowly. 9
MS (12a)

Melting Fine Silver in High-Frequency Induction Furnace. DANIEL L. OGDEN. *Brass World,* Vol. 28, July 1932, page 144.

Operating data are tabulated for an Ajax-Northrup induction furnace rated at 100-kw. and the melting of 429 kg. of Ag per charge. The direct savings do not warrant the high installation cost, but the cleanliness, ease of operation, and lack of metal loss have been distinctly advantageous. 10

Quantity Production of Stainless Steel. J. A. McWilliam. *Iron & Steel of Canada,* Vol. 15, June 1932, pages 71-73.

Address before the Montreal Chapter, A.S.S.T., in which the author deals with the general problem of the manufacture of stainless steel and with certain of the uses to which these alloys, particularly Firth's "Staybrite," have been put. OWE (12a)

On Basic Open-Hearth Slags. (Beitrag zur Frage Basischer Siemens-Martin Schlacken.) Alfred Klaus & N. Wark. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 603-608.

Report 230 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. 3 special and complete runs were made to determine amounts of Fe and Mn passing into the slag as affected by the basicity of the slag The ratio $\frac{CaO}{SiO_2} = v$ is used to designate basicity. The composition and weight of charge, analysis of steel and slag, amount of ferromanganese for deoxidation, and Fe and Mn losses during course of process, with varying v ratios of 0.83 to 4.01 for the 3 charges are completely tabulated. These 3 tests and the results of a series of supplementary tests confirm the previously established conclusions, that during the melting and deoxidation period the Fe loss to the slag decreases with increasing SiO_2, while it increases with rising basicity. The relation of Mn loss to degree of basicity of the slag is not exactly clear and definite, or at least not as clearly defined as for Fe loss. The amount of slag apparently affects the Mn loss. The relation and the effect of SiO_2 content and amount of slag are given. In addition there are also brought out the reciprocal relations between oxide content of the slag and the amounts of O and reducing agents of the metal bath. Includes discussion. DTR (12a)

Carbon-oxygen Equilibrium in Liquid Iron. H. C. Vacher & E. H. Hamilton. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 124-140.

Includes discussion. See *Metals & Alloys,* Vol. 2, July 1931, page 134. (12a)

Processing of Copper Sand Castings of Highest Conductivity. Deoxidation with Beryllium. (Herstellung von Kupfersandguss höchster Leitfähigkeit. Desoxydation mit Beryllium.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, May 29, 1932, page 226.

Be is the only deoxidizer which permits producing Cu of highest electrical and thermal conductivity with greatest effectiveness. Cu used, melting process, deoxidation, casting and mold are discussed. Deoxidation is performed immediately upon removing the crucible from the furnace. About 110- 120 g. of a 10% Be- Cu alloy are sufficient for deoxidizing 100 kg. of Cu. Pieces of this alloy, wrapped in Cu-foil, are stirred into the melt. For stirring graphite coated iron bars are used. GN (12a)

The Deoxidation of Copper by Means of Metallic Calcium, Zinc, Beryllium, Barium, Strontium and Lithium. (Die Desoxydation des Kupfers mittels metallischen Kalzium, Zink, Beryllium, Barium, Strontium und Lithium.) *Die Metallbörse,* Vol. 22, May 28, 1932, pages 674-675.

The danger that a surplus of the added deoxidizer is liable to alloy with Cu and reduce its electric conductivity is stressed. Ca up to 0.4% hardly influences the physical properties of hard drawn Cu wire. A surplus of Ca is insoluble in Cu and largely affects the conductivity. Up to 0.2% Ca, the electric conductivity is reduced 10% by each 0.05% Ca. According to the writer, Ca is a very suitable deoxidizer. Zn up to 0.4% reduces but slightly the physical properties of hard drawn Cu. Up to 0.3% Zn, the electric conductivity drops 0.8% by each 0.05% Zn. Regarding Be, 0.05% reduces the conductivity about 10%. The effects of Ba, Sr, and Li are shown in a table. Ba and Sr are favorable deoxidizers, but the initial costs are too high. Li readily oxidizes and quickly reacts with refractory material of the furnace. EF(12a)

The Desulphurization Reactions in the Present Methods of Production of Steel and Pig Iron. (Beitrag zur Frage der Entschwefelungsvorgänge bei den heutigen Verfahren der Stahl- und Roheisenerzeugung.) Clemens Bettendorf & Nicholas J. Wark. *Stahl und Eisen,* Vol. 52, June 16, 1932, pages 577-582; June 23, 1932, pages 606-612.

Report 231 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion. The subject is treated in 2 parts; the first part dealing with a laboratory study of various conditions affecting desulphurization of pig Fe and steel, while in the second part the laboratory results were checked by tests carried out on a large scale in regular operation. Melts of different classes of steel were made in a low frequency electric furnace, electric arc furnace, straight and tilting open-hearth furnace, while for foundry pig Fe, desulphurization was followed in the blast furnace. The authors summarize their work as follows: For rapid and good desulphurization the most important preliminary conditions along with time of reaction and a suitable temperature, are a high degree of basicity and a large amount of slag. Lime is the basic material in eliminating S. Its action in removal of S is heightened, if the lime is dissolved in a solvent such as fluorspar, bauxite or the like. SiO_2, instead of fluorspar, has a favorable effect only with small additions. Fluorspar permits S in the slag to escape as volatile matter. Through reduction of the S content in the slag it can then take up new amounts of S from the bath. A higher Mn content of the metal bath likewise yields better desulphurization. By the use of stronger bases, such as strontia, potash, soda, the desulphurizing action of the slag may be considerably improved. The alkali chlorides, rock salt, sylvite, carnellite, are also good expedients, acting as reducing agents in the bath. A further rise in desulphurizing action of properly-composed slag occurs, if these reducing agents are present. With the maximum action of these reducing agents (carbide formations in electric furnace), the maximum S removal is attained. In addition several comparative considerations are presented on S removal in the blast furnace. Includes discussion. 23 references. DTR (12a)

Casting & Solidification (12b)

For Users of Cylindrical Shapes. *Inco,* Vol. 11, No. 2, 1932, pages 9-10.

The practice of centrifugal casting is discussed and the advantages due to uniformity of wall thickness of pipes or of the covering when cast on other parts are pointed out. Besides, impurities are separated due to the pure metal being heavier and thus pressed to the outside, oxides, gas, slags, etc., floating on the interior surface; a very dense casting is therefore produced having great uniformity of structure and high tensile strength. The following table shows comparative figures for some centrifugally cast metals and alloys:

Composition	Copper	Standard Bronze	Gunmetal	Manganese Bronze	Monel Metal
Copper	100	85-87	86-89	55-60	23 min.
Tin	—	4-6	7.5-11	1.5	—
Zinc	—	4-6	1.5-4.5	38-42	—
Lead	—	3-5	0.3 max.	0.2 max.	—
Nickel	—	0-1	0.75 max.	—	60 min.
Manganese	—	—	—	3.5 max.	3.5 max.
Aluminum	—	—	—	1.5 max.	—
Iron	—	—	—	0.4-2.0	3.5 max.
Carbon & Silicon	—	—	—	—	2.0 max.
Average Tensile Strength lb./in.²	25,000 to 27,000	33,000 to 45,000	44,000 to 49,000	65,000 to 110,000	65,000 to 100,000
Average Elongation %	40 to 45	20 to 25	25 to 35	15 to 20	15 to 25

A few examples of special cases where very thick layers were cast are described. Ha (12b)

Instantaneous Conversion into Ingots of Metals and Alloys on Casting. (Le lingotage instantané des métaux et alliages à la coulée.) *Journal du Four Electrique,* Vol. 41, June 1932, pages 215-216.

Teeming of ferro alloys through a nozzle into ingot molds always causes too much liquation and non-uniformity in composition. Casting them on the floor and crushing produces too much dust and losses. A combination of ladle and ingot mold solves the problem. The ladle is semi-cylindrical and is supported on trunnions provided with proper gearing for turning it around its horizontal axis. The metal is tapped into it as usual, the slag is removed by appropriate means and a lid is fastened to its top. The lid actually forms a heavy chill capable of holding all the metal in the ladle. Rotating the ladle the metal is transferred into the lid and solidifies there almost instantaneously without any liquation whatever. The apparatus was successfully used in the plants making ferro silicon. JDG (12b)

Causes of Warping in Casting Pipes. (Ursachen für das Krummwerden von Rohren beim Giessen.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 26, 1932, pages 259-260.

The various causes of warping in casting pipes are enumerated, the remedies are discussed. GN (12b)

Liquation or "Inverse Segregation" in the Silver-Copper Alloys. J. H. Watson. *Institute of Metals, Advance Copy* No. 620, Sept. 1932, 12 pages.

Liquation or inverse segregation was studied by holding various alloys at a temperature between the liquidus and solidus for several hours and then either slowly cooling or cooling in such a manner as to chill only a portion of the melt. The primaries of Ag or Cu were free to rise or fall under the influence of gravity. In a Cu-rich alloy the top was enriched in Cu due to the rise of the Cu primaries. In the slowly cooled Ag alloys the top was enriched in Cu due to the falling of the heavy Ag-rich primaries. It was also established that the primaries which have segregated under the influence of gravity are repelled from their position by the application of severe local chilling in their vicinity. The effects observed in these alloys in ordinary practice can be explained by the formation of primaries at the chilling surfaces of the mold and between the temperatures of the liquidus and solidus, followed by their immediate migration towards the hotter portions of the mass. Segregation in several complex coinage alloys was also studied. JLG (12b)

Change in Composition of Steel and Slag During Tapping from Furnace into the Ladle and During Casting into Ingot Shapes. (Veränderung der Zusammensetzung von Stahl und Schlacke beim Abstechen aus dem Ofen in die Pfanne und beim Vergiessen in die Blockformen.) Nicholas J. Wark. *Archiv für das Eisenhüttenwesen,* Vol. 5, Apr. 1932, pages 503-510.

Report 225 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion. Different classes of steel, produced in a 15-ton Heroult and in 17 and 65-ton open-hearth furnaces, were studied. Changes occurring during tapping of steel and slag into ladle and during casting period were all tabulated. During casting of electrolytic steel no appreciable changes occurred between metal and slag due to low metal oxide slag. Far different was the behavior with rich metal oxide open-hearth slag. With non-Si soft ingot steel, Mn dropped toward the end of the casting period, while P and S increased. With Si-steel, Mn increased toward end of casting, while Si decreased. Also P increased directly with amount and fluidity of slag. S remained constant, but if an increase in S was found in an exceptional case, this increase was never as high as in case of non-Si soft ingot steel. Precautions for reducing combinations between metal and slag are given. Using suitable methods the composition changes of steel may be greatly diminished. Ladle slag may be distinguished from furnace slag by reduction in CaO. Strong increase in SiO_2 and Al_2O_3 and changes vary with different brands of steel. The hotter layer of ladle slag in immediate contact with metal bath reacts more vigorously and produces more changes than the top heat-radiating layer. Simultaneous with SiO_2 increase, decomposition of reducible oxides occurs in ladle slag. DTR (12b)

Casting of Roll-like and Cylindrical Bodies. (Das Giessen von walzenförmigen und zylindrischen Körpern.) G. KREBS. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 24, 1932, pages 287-289.

Chemical composition, production, properties and testing of castings for piston rings and cylinders are discussed. The advantages of hot casting are emphasized, as favorable crystallization of graphite and separation of occluded gases. GN (12b)

Rolling (12c)

Why Sheets are Thicker at Center. W. H. MELANEY. *Blast Furnace & Steel Plant,* Vol. 20, Jan. 1932, pages 61-63; *Iron & Steel of Canada,* Vol. 15, Feb. 1932, pages 15-16.

Thin plates and sheets have a greater thickness at the center than at the edges. Common explanation for this condition is that the rolls bend at the center of their length, thus producing a slightly greater aperture at the center of the roll face. Author attempts to disprove this theory by pointing out that rolls of the 2-high type are of such massive proportions as to preclude any spring; that the larger the diameter of the plate rolls, the greater is the difference in thickness, other conditions remaining the same; and that in 3-high and 4-high mills using small diameter rolls, there is less difference in gage between middle and edges. Advances the theory that the elastic restoration of the metal being rolled is primarily responsible. In rolling a sheet, the steel flows sidewise as well as lengthwise. The side flow is from the center toward each side, but as the molecules in the center are resisted in their motion by all those from the center to the sides, they are forced to pile up there. The resistance becomes gradually less as the molecules approach the sides, resulting in a gradual reduction of the thickness from the center to each side. On emerging from the rolls, elastic restoration takes place in proportion to the stress set up, and as this was greater in the center, the metal comes back more in the middle and produces the heavier gage. OWE+MS (12c)

What Happens when Rolling Thin Sheets. W. H. MELANEY. *Blast Furnace & Steel Plant,* Vol. 20, Apr. 1932, pages 335-337.

Lubrication of the roll faces during rolling and tension on the sheet in the direction of the flow of the metal during reduction produce less crown on the sheet. These conditions can be explained by the author's theory of elastic restoration of the metal published in *Blast Furnace & Steel Plant,* Jan. 1932. Much more attention should be given to the roughing stage and to obtain the correct shape of roughed sheets, so as to reduce troubles on the finishing rolls. Pinched sheets are caused by the rolls' biting of the edges of the pack before the center, thus forcing the flow of the metal toward the center where it piles up and laps over. End of properly roughed sheet should have a slightly concave curve with corners slightly rounded. Steam should be applied to the face of the rolls through perforated pipes; the sizes of the openings being reduced from the center toward each end. The proper shape of the rolls can thus be maintained. MS (12c)

Electric Roll Heaters. *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 272-273.

makes good steel better

Ferro Carbon-Titanium Plays a Dual "Cost Cutting" Role in Industry Today

To the steel castings manufacturer, Ferro Carbon-Titanium means increased yield of good product—cleaner, more uniform steel—a more ductile, durable product, free from segregations or inclusions.

To the consumer of steel castings, Ferro Carbon-Titanium often means less grinding, polishing and buffing—fewer rejects—greater security against hidden defects.

If you *make* steel castings, add Ferro Carbon-Titanium at the ladle for superior quality and fewer rejections. If you *buy* steel castings, specify Ferro Carbon-Titanium as insurance against unexpected production costs.

Tools, Contrivances and Equipment for Turning and Grinding Sphere-Shaped Parts. (Werkzeuge, Vorrichtungen und Einrichtungen zum Drehen und Schleifen kugliger Werkstücke.) A. Winter. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 8, July 10, 1932, pages 77-79.

Discusses tools and other equipment to be used for economically turning sphere-shaped parts. GN (12g)

Chromium Plating of Tool Cutting Edges. (Verchromen von Werkzeugschneiden.) *Technische Blätter der deutschen Bergwerkszeitung,* Vol. 22, Aug. 14, 1932, page 433.

Tools with Cr-plated edges are particularly suitable for machining light metals. Use and advantages of Cr-plated tools are briefly discussed. The life of such tools is increased considerably, for instance, reamers stand up 25 times longer than non-Cr-plated, files 3-8 times longer. GN (12g)

Machining the Magnesium Alloy Elektron. *Machinery,* Vol. 38, Mar. 1932, pages 532-533.

Elektron is a light weight alloy consisting chiefly of Mg with Al, Mn, Zn and Si in variable amounts. Specific gravity 1.8, tensile strength from 6.3 to 25.3 tons/in.^{2}, compressive strength 19 to 28.6 tons/in.^{2}, elongation 2 to 18%, Brinell hardness 42 to 90. Varying composition accounts for this range of properties. Melting point 1200° F. Not affected by alkaline solutions. Corrodes slightly when exposed to air. Discusses applications, and machining methods. RHP (12g)

The Chippability of Cast Steel in the Drilling Process. (Die Zerspanbarkeit des Stahlgusses im Bohrvorgang.) A. Wallichs & H. Beutel. *Die Giesserei,* Vol. 19, June 24, 1932, pages 241-247.

Contrary to the facility of turning cast steel the possibility of its being drilled is greatly influenced by the formation of the chips which cannot be removed so readily as in turning. An investigation of various steel material showed, just as for turning, a dependence on the hardness of the material. Increasing contents of C and especially of Si reduce the drillability. A refined Cr-Ni steel is more difficult to drill than an unrefined steel. A higher tempering temperature improves the drillability. Ha (12g)

New and Improved Tools at the Leipzig Technical Fair 1932. (Neuartige und vervollkommene Werkzeuge auf der Technischen Messe 1932.) Schlippe. *Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 8, May 10, 1932, pages 53-56.

Description of cutting and measuring tools. GN (12g)

On a New Method to Increase the Durability of Cutting, Stamping, Pressing and Forging Tools. (Über ein neues Verfahren zur Verlängerung der Lebensdauer von Schnitt-, Stanz-, Press- und Schmiedewerkzeugen.) *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 65, Apr. 10, 1932, page 49.

The life of tools for the above purposes can be increased by heating them during the operation. Several examples are given. By cutting, for instance, a steel sheet with 1.28% C and about 2% Cr the cutting edge of the straight carbon blade stood up before re-grinding 35,000 cuttings; however, by heating the blade to 175° C. it made 65,000 cuttings. Similar favorable results were obtained in heating forging dies. GN (12g)

Tests of New High Speed Tool Steels for Improvement of Efficiency. (Prüfung der Wirtschaftlichkeit neuer Werkzeugstähle zwecks Verbesserung der Werkstattleistung.) W. v. Schütz. *Maschinenbau,* Vol. 11, Jan. 21, 1932, pages 33-37.

For any fixed program of production and any given equipment, a method is presented for selecting the most economical (not necessarily the best in quality) kind of tools to be employed. 7 references. RV (12g)

New Developments in Machining Aluminum and Its Alloys. R. L. Templin. *S. A. E. Transactions,* Vol. 25, 1930, pages 275-278. See *Metals & Alloys,* Vol. 2, Feb. 1931, page 43. (12g)

Vibration-less Machining of Hollow Bodies. (Erschütterungsfreie Bearbeitung von Hohlkörpern.) O. P. van Steewen. *Maschinenkonstrukteur-Betriebstechnik,* Vol. 65, May 10, 1932, pages 54-55.

The outside wall of thin-walled tubes can be machined with the greatest accuracy when, before machining, the tube is filled with a liquid of small thermal expansion and small elasticity, for instance, water or oil. During machining any heating should be avoided. GN (12g)

The Chippability of Materials. (Die Zerspanbarkeit der Werkstoffe.) W. Leyensetter. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns,* Vol. 1, Mar. 1932, pages 243-256.

In order to be able to compare the various cutting or chipping conditions a so-called cutting characteristic is developed = $l/s \times t$, where l is the length of the arc of the cut, s the feed and t the depth of the cut. With this characteristic the various metals can be classified with regard to their machinability and their relations to other properties be investigated. Ha (12g)

Cemented Tungsten Carbide for Cutting Tools. L. J. St. Clair. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 139-146.

Polishing & Grinding (12l)

A Survey of Surface Quality Standards and Tolerance Costs Based on 1929-1930 Precision Grinding Practice. R. E. W. Harrison. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 111-125.

The paper reviews some of the defects existing in present-day standards of finish of mechanical components. Size control and its effect on cost of production is discussed, a scheme for the establishment of definite standards is suggested and a finish-calibrating instrument described. No short cut method to high quality work is available with a low factor of initial wear. Photographs of ground, polished and lapped surfaces are given. Ha (12l)

Fundamentals of Machine Polishing. Robert T. Kent. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 73-84.

The various factors entering in effective and economical polishing, as the polishing wheel, the abrasive, the glue used in setting up the polishing wheel, are discussed in relation to one another. Types of polishing machines and examples of successful machine polishing are described and illustrated. Ha (12l)

Refinements in Finishing Cylindrical Bores. J. W. Hindes & James G. Young. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 127-130.

The limitations of boring, reaming, burnishing and broaching as finishing operations on cylindrical bores have led to a general use of abrasives. The advantages of the expanding grinder, which consists of an expanding segmental wheel with a grinding surface being composed of a series of abrasive stones placed longitudinally upon the circumference of a metal body with an adjusting means for expanding the stones are described; they are essentially perfection of finish both as to straightness and roundness, absence of fuss, accuracy not dependent on skill of operator, high-speed production and low cost. Ha (12l)

Automatic Worm-Gear Grinding Machine with Hydraulic Adjustment of the Spindle Stock. (Selbsttätige Schneckenschleifmaschine mit hydraulischer Zustellung des Schleifspindelstocks.) Weil. *Die Werkzeugmaschine,* Vol. 36, Aug. 15, 1932, pages 279-281.

Illustrated description of the machine built by J. E. Reinecker A.-G. Chemnitz, Germany. GN (12l)

Micrometer Lap. F. J. Wilhelm. *Modern Machine Shop,* Vol. 5, July 1932, page 34.

A satisfactory way of lapping the end of a micrometer spindle by using a lap and a hub is described. It insures a perfect seat against the anvil of the micrometer. Ha (12l)

Technology of Grinding Tools in Precious Metal Industry. (Technologie des Werkzeugschliffs in der Edelmetallindustrie.) *Deutsche Goldschmiedezeitung,* Vol. 35, May 7, 1932, pages 192-195.

Detailed discussion of the grinding of tools to be used in the precious metal industry with special reference to the grinding materials used. GN (12l)

Application and Efficiency of Grinding Machines. (Schleifmaschinen, ihre Verwendung und ihre Wirtschaftlichkeit.) Meyer. *Zeitschrift für wirtschaftliche Fertigung,* July 1932, pages 91-92.

After an introductory discussion on the grinding process recent German constructions of grinding machines are described with special reference to their efficiency. GN (12l)

Coloring (12m)

Electrolytically Produced Oxidic Protective Coats on Aluminum and Its Alloys, in Particular for Metal Coloring. (Elektrolytisch erzeugte oxydische Schutzschichten auf Aluminium und dessen Legierungen, besonders auch für Zwecke der Metallfärbung.) Geo. Buchner. *Oberflächentechnik,* Vol. 9, June 21, 1932, pages 127-128.

Anodic oxide films on Al have 3 important properties: (1) the valve effect, (2) high insulation quality, and (3) the high protective value against corrosion and erosion, both chemical and mechanical. At the same time coloring effects can be produced if solutions of chromic acid, dilute H_2SO_4, oxalic acid, borax, boric acid, etc. are used. The oxide film is hard and can be polished with hard powders. The best current density is from 1 to 10 amp./dm.^{2}, the films are the harder the higher the voltage applied. Pure Al gives harder oxide films than the Al alloys. The color of the oxide layer depends on the thickness of the latter, on the electrolyte and also on the base material. Oxalic acid on pure Al produces yellow to brown depending on the thickness. Al oxide films can be dyed with organic dying materials in all colors by immersing them in the boiling color solutions. Ha (12m)

Sand Blasting (12n)

The Cleaning of Castings. (Le Dessablage des Pieces de Fonderie.) E. Tourneur. *Revue de Fonderie Moderne,* Vol. 26, May 10, 1932, pages 149-159.

The methods used in cleaning castings of sand are described and their economy discussed. The usual abrasives are sand and steel grit. The size of the grains of sand used for different materials are recommended as follows:

For Al	Approx.	0.5 mm.
brass	"	0.5-1.0 mm.
bronzes	"	1-2 mm.
small Fe castings	"	2 mm.
medium Fe castings	"	3 mm.
large Fe castings	"	3-4 mm.
steel	"	4-5 mm.

If steel grit is used the grains should be preferably angular. The pressures used for best results are given as:

Metal	Pressure with sand	Pressure with steel grit
Al, brass	0.8-1.2 kg.	1-2 kg.
bronze	1-1.5 kg.	1.5-2.4 kg.
cast Fe	2-2.5 kg.	2.5-3 kg.
steel	2.5-3.5 kg.	3-4 kg.

Several constructions of sand-blasting apparatus and auxiliary devices are described. Ha (12n)

Strain at Complicated States of Stresses. (Beitrag zur Anstrengungsfrage bei zusammengesetzten Spannungszuständen.) J. Bach. *Ingenieurarchiv*, Vol. 2, Jan. 1932, pages 604-605.

The author shows in 2 cases that under the conditions given the theory of the largest change of shape is in better accordance with the testing results than the hypothesis of principal stresses. It is known that the hypothesis of principal stresses is not verified with other states of stresses and materials than those considered. However, the theory of the largest change of shape proved to hold true in all cases investigated, for brittle as well as tough materials. GN (20)

Investigation of Materials of Old Steam Boilers. (Werkstoffuntersuchungen an alten Dampfkesseln.) K. Daeves, E. Pfeiffer & G. Urbanczyk. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, June 4, 1932, pages 551-556.

The material of 11 different boilers which had been in service from 22 to 44 years was examined under present conditions. No great changes of property in the boiler plate could be found but there existed a strong brittleness in all riveted seams. There was only a minor sign of corrosion. It is stated that it is risky to repair or move such boilers. Ha (20)

The Calculation of Torsional Vibrations in Crankshafts by means of the Table on Frequency Functions. (Die Berechnung der Drehschwingungen von Kurbelwellen mittels der Frequenzfunktionen-Tafel.) R. Grammel. *Ingenieurarchiv*, Vol. 3, June 1932, pages 277-297.

The method developed by the author in former investigations (*Ingenieurarchiv*, Vol. 2, 1931, page 288; Vol. 3, 1932, page 76) on the calculation of free and forced torsional vibrations in crankshafts gives formulae which are easily evaluated by the tables of so-called frequency functions. The formulae have been checked for 19 various types of machines. 3 references. GN (20)

The Kinetics of the Decomposition of Ammonia on Copper. J. K. Dixon. *Journal American Chemical Society*, Vol. 53, May 1931, pages 1763-1773.

In this study it was found that no appreciable amount of Cu nitride formed, and that small amounts of CO poisoned the surface of the Cu. MEH (20)

Extraction of Beryllium, Caesium, and Rubidium from Beryl. C. James, H. C. Fogg & E. D. Coughlin. *Industrial & Engineering Chemistry*, Vol. 23, Mar. 1931, pages 318-320.

A simple and economical method has been developed for producing pure beryllium oxide from beryl, using ordinary chemicals and apparatus. Any small quantity of caesium and rubidium which may be present in the mineral can be obtained at the same time. The method is applicable either on a commercial or laboratory scale. With only a few changes, the principles of this method can be adapted to the extraction of these elements from other silicate minerals. MEH (20)

The Collapsing Strength of Steel Tubes. T. McLean Jasper & John W. W. Sullivan. *Transactions American Society of Mechanical Engineers*, Vol. 53, 1931, Applied Mechanics, pages 219-245.

An analytical treatment is given for the determination of the collapsing strength of steel tubes on the basis of the physical and elastic properties of the metal in the tube, and the dimensions, out-of-roundness, and variations in the thickness of the tube. The formulas are developed in terms of compressive stress instead of external pressure and examples of commercial tubes are treated for the illustration of the method. In an appendix is described the experimental work done by the A. O. Smith Corporation and another appendix reviews the work of previous investigators in this subject. Several tables are compiled showing the collapsing pressure with respect to physical dimensions. Ha (20)

Spark Analysis in the Machine Shop. (Die Funkenanalyse im Werkstättenbetrieb.) A. Herr. *Werkzeugmaschine*, Vol. 36, July 15, 1932, pages 240-241.

The paper discusses the spectroscopic investigation of materials. The advantages of the spark analysis are outlined. Local fluctuations of the chemical composition are to be detected that cannot be detected by chemical analysis. Examination of tool steel and steel scrap is discussed. Quantitative determination of the following elements is impossible: V, above 1%; Ti, 0.168% and more; Ni, 0.1%; Cr, 0.5%. GN (20)

Analysis of Stresses in Circular Plates and Rings. E. O. Holmberg & K. Axelson. *Transactions American Society of Mechanical Engineers*, Vol. 54, Jan. 30, 1932, Applied Mechanics, pages 13-28.

A theoretical investigation with special regard to application to cylinders with rigidly attached flat heads and flanges. A simplified method is derived for the calculation of stresses in flat, circular plates with or without hole in the center and with loads uniformly distributed around the center. Ha (20)

Torsional Vibrations in Crank Shafts. (Erzwungene Torsionsschwingungen in Kurbelwellen.) S. Gradstein. *Ingenieurarchiv*, Vol. 3, May 1932, pages 206-214.

The vibrations in crank shafts were studied by a method developed by W. Prager (*Ingenieurarchiv*, Vol. 1, 1930, page 527). The vibrations were studied in the various sections of a shaft which had been loaded with flying disks. From the dimensions of the shaft, the amplitudes of the vibrations, the phases and frequencies of the exciting torques the deflections of the shaft and the stresses thus originating were calculated. 4 references. FOUNDRY PRACTICE & APPLIANCES (22)

Superheating and Heat-treating of Grey Cast Iron. J. W. Donaldson. *Metallurgia*, Vol. 6, June, 1932, pages 49-52.

Mainly a review of published work on these subjects. JLG (22)

1 **New Process Manufacture of High-Duty Cast Iron.** *Metallurgia*, Vol. 6, June 1932, pages 35-38.

Points out advantages of rotary melting furnaces, and describes installation at W. G. Armstrong Whitworth and Co. plant. A high-test iron suitable for both large and small castings can be produced in these furnaces. JLG (22)

Processing of a Mold for the Casting of Armature Casings. (Herstellung einer Kokille zum Giessen von Armaturgehäusen.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, June 12, 1932, pages 244-245; June 26, 1932, pages 266-268.

2 Detailed discussion of the procedure to be followed. GN (22)

Discusses Manufacture of Titanium Aluminum Bronze. Charles Vickers. *Foundry*, Vol. 60, Mar. 1, 1932, pages 36-40; Apr. 1932, pages 44-45, 82, 84.

A series of 2 articles on the development and founding of Ti-Al bronze. Ti-Al bronze is a modern Cu, Fe and Al alloy and contains only traces of Ti, developed in 1916. Investigations to discover a degasifier which would give satisfactory results led to the development of a combination of which Ti was one. To obtain the desired homogeneity in degasifying
3 alloy it was necessary to melt it twice. Good results could be obtained by making first a primary alloy which combined with other elements to form the final alloy. VSP (22)

Processing of a Ship Screw Hub in Loam and Sand Mold respectively. (Herstellung einer Schiffspropellernabe in Lehm- bez. Sandform.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, July 10, 1932, pages 285-289.

Detailed and illustrated description of the procedure in loam or sand molding the hub of a ship screw. GN (22)

The Production of Malleable Iron in the Cupola with Higher Amounts of Scrap and High Silicon Cast Iron in the
4 **Burden. (Die Herstellung von Temperguss im Kupolofen bei Verwendung von höheren Schrottzusätzen und hochsilizierten Roheisensorten.)** H. Springkämper. *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, June 26, 1932, pages 254-257.

On the basis of tests and practical experience the author states that the use of higher amounts of scrap and high Si cast Fe offers no economic advantages in processing malleable Fe. There are also metallurgical difficulties due to fluctuations of the Si content and increase of the S content. The author is of the opinion that the disadvantages of the scrap process which is advocated by Stotz (*Zeitschrift für die*
5 *gesamte Giessereipraxis*, Vol. 55, Jan. 24, 1932, pages 42-44; Feb. 7, pages 58-59) become evident only in the course of time. Calculations on the economy of the pig Fe and the scrap process for making malleable Fe. GN (22)

The Working of Rotary Pulverized Fuel Fired Melting Furnaces. W. Scott & S. E. Dawson. *Foundry Trade Journal*, Vol. 46, June 2, 1932, pages 335-338.

An article, accompanied by discussion, which deals with the practical considerations of metal-melting in rotary furnaces of the Sesci type, and discusses the metallurgical considerations of the process. The article deals almost entirely
6 with the manufacture of cast Fe. OWE (22)

Effect of Temperature on Physical and Casting Properties of No. 12 Aluminum Alloy. George H. Starmann. *Metal Industry*, N. Y., Vol. 30, May 1932, pages 181-182.

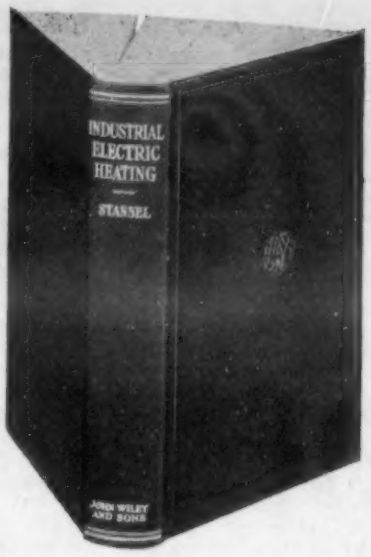
Experimental results are given showing that the physical properties of No. 12 Alloy, cast in sand, decrease as the pouring temperature is raised above 1300° F. The effect of high melting temperature is markedly less harmful than that of high pouring temperature. Indications are that soaking at high temperatures has an effect upon the metal not produced
7 by soaking at normal temperature. PRK (22)

On the Distortion of Large Castings. (Ueber das Verziehen von langen Gusstücken.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, May 29, 1932, pages 217-220.

The paper deals with practical experience to avoid warping of large castings. The molding practice is particularly considered and outlined in several examples. GN (22)

Core-prints and Locating of Cores. (Kernmarken und Kernlagerungen.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, July 24, 1932, pages 296-297; Aug. 7, 1932, pages 315-318.

8 The paper discusses the proper locating of cores, as for columns, pipe joints, radiator parts, drainage pipes, etc. Practical examples are given. GN (22)



The Properties of Good Glues for Pattern Making and Its Liquefaction. (Die Eigenschaften guter Holzleime für den Modellbau und ihre Verflüssigung.) *Zeitschrift für die gesamte Giessereipraxis*, Vol. 53, Aug. 21, 1932, pages 336-337.

The paper discusses the properties of bone-glue and skin-glue. Color and transparency are not always indicative of quality. Of prime importance for the quality is the content
9 of gluten. Soaking and the processing of glue-solution must be done carefully to attain highest bonding capacity. Proper heating apparatus is required. GN (22)

Ferrous and Non-Ferrous Metals in the Foundry. W. Rosenhain. *Foundry Trade Journal*, Vol. 46, June 9, 1932, pages 354-356, 358.

The author opens his paper by analyzing the differences between ferrous and non-ferrous metals with the view of indicating the problems which are common to both. Considerable attention is directed to the role of metallic molds in foundry practice. The subjects of mold dressings and core
10 binders are dealt with in some detail, the author criticizing the use of so-called "flaming" dressings, pointing out very clearly the dangers which may arise from the use of such materials. The corrosion of cast alloys receives brief attention, and the question of competition from forged materials is likewise discussed. The author refers in closing to the inspection, sampling and testing of castings. OWE (22)

ANNOUNCING

INDUSTRIAL ELECTRIC HEATING

By

N. R. STANSEL

Associate Member A. I. E. E., Industrial Engineering Department — General Electric Company.

THIS book presents in concise form the more important principles of industrial heating and correlates with that presentation current practice in the industrial use of electric heat.

"Industrial Electric Heating" deals with the technical phase of electric-heat as the first step in its economical utilization. It is significant to the manufacturer as a new tool in which may be found the solutions of many manufacturing problems in which heat is a factor. The design of each type of electric furnace is presented as the introduction to its applications within the field for which it is designed. Typical applications of electric furnaces are described both to give some information regarding specific uses of electric-heat and to illustrate its diversification in manufacturing.

H. W. GILLETT,
Director of Battelle Memorial Institute says—

"The book is noteworthy for the things it doesn't waste space on and for the clarity and conciseness of what it does present. The author's long experience with the General Electric Company in the lines covered by the book has enabled him to treat his subject with authority. Besides being a highly informative volume, it is an extraordinarily good job of technical writing."

CONTENTS

Introductory; The Transfer of Heat; Heating and Cooling of Metals; Electric Heating; Heating Chambers; The Resistor Furnace; Atmosphere of Resistor Furnaces; Applications of the Resistor Furnace; Melting Metals; Melting Pots—Resistor Type; Arc Furnaces; Induction Furnaces; Supplement; Factors Affecting the Economics of Industrial Electric Heating; References.

444 pages—$5.00

FURNACES & FUELS (23)

Industrial Electric Heating. N. R. STANSEL. John Wiley & Sons, Inc., New York, 1933. Cloth, 6¼ x 9¼ inches, 444 pages. Price $5.00.

1 Electric furnaces are important tools in metal melting, in heat-treating and in many other processes with which the metallurgist is concerned. While this book has a broader title and a broader scope than metallurgy alone, nearly every page is of metallurgical interest.

Stansel's method of attack upon a problem in electric heating is to survey the process to be carried out from the point of view of the chemical and physical requirements and limitations, and from these to engineer the equipment that will serve those needs. Hence, there is straight-to-the-point discussion of heat transfer, effect of heat on metals, effect of furnace atmosphere, electrical properties of furnaces, etc., 2 which, though aimed at electric furnaces in particular, is good fundamental heat engineering and valuable to many who may not be directly interested in electric furnaces. The points are driven home by specific examples of typical furnaces and their application, but so deftly is this done that minor details germane only to a single application are pretty much avoided and each example serves to bring out general truths. The illustrations and curves are well chosen. Each one clarifies the text. The engineer who studies the book will therefore not find his mind cluttered up with a mass of useless details, but instead will obtain a good foun- 3 dation of essential principles, widely applicable, and will be led to sound methods of thinking. It is not a college text book nor a handbook of data, but is extremely well fitted for the self-improvement of the graduate engineer or metallurgist up against heating problems.

The book is gratifyingly free from sales propaganda harping on the superiority of electric over fuel-fired furnaces. The final chapter discusses some of the elements of an economic choice among furnaces, and of course, the fitness of the electric furnace for given types of service is brought out all along, but in general, the assumption is made that the furnace user is seeking a result best obtained by elec- 4 tric heating and one that will stand the first cost, and the discussion proceeds from there.

The book does not cover everything that its title might include. It does not deal with the lowest temperature ranges, such as those involved in curling irons, core ovens, etc., nor does it deal with ferro-alloy production. Many of the principles discussed are, of course, applicable to the subjects not covered. The subjects dealt with are primarily those in which the greatest number of industrial furnace users are concerned. One omission which metallurgists will wish had not been made is that of nitriding to which only casual ref- 5 erence is given.

Batch and continuous resistor furnaces of types suitable for heat-treatment of steel, annealing of non-ferrous metals, enameling, annealing of glass, etc., are well covered. Metal melting is dealt with from type metal up through brass and steel, involving rather thorough treatment of external and submerged heating units, direct and indirect arc furnaces, vertical ring and high frequency induction furnaces. There is very interesting discussion of hydrogen brazing.

Obsolete furnaces are not discussed. Few authors would 6 have shown the restraint that Stansel has in ruthlessly omitting the historical and confining himself to matters of present engineering interest. The book is noteworthy for the things it doesn't waste space on and for the clarity and conciseness of what it does present. The author's long experience with the General Electric Company in the lines covered by the book has enabled him to treat his subject with authority. Beside being a highly informative volume, it is an extraordinarily good job of technical writing. 115 references. H. W. Gillett (23)-B-

Heat Exchange in Modern Industrial Practice. II, III. BASIL HEASTIE. *Industrial Chemist*, Vol. 8, Mar. 1932, pages 87-89; 7 May 1932, pages 172-174.

With the first article of this series appearing in Nov. 1931, these articles comprise a discussion of various methods and formulae. The author attempts to correlate existing data. RAW (23)

Copper and Heating with Heavy Oils. (Le Cuivre et le Chauffage aux Huiles Lourdes.) *Cuivre et Laiton*, Vol. 5, June 30, 1932, pages 271-272.

8 The use of heavy oils, as mazout, etc., as fuels for industrial furnaces, particularly in the Cu industry, is discussed. Automatic regulation of combustion and temperature, safety and cleanliness are advantages. Burners use any pressure up to 700 g./cm.² and higher; medium pressure burners (150 to 400 g./cm.²) are at present those most generally employed for industrial furnaces. A few constructions are described. Ha (23)

Cleaning Coal. RALPH H. SWEETSER. *Blast Furnace & Steel Plant*, Vol. 20, Feb. 1932, pages 171-174.

Discussion of papers on coal cleaning read at the Third International Conference on Bituminous Coal, Nov. 1931. 9 Proposes that the coal industry adopt as a base-line for evaluating all coals the analysis of the coal as shipped. The base-line percentage of total ash + moisture should be set at 12.7% as this is a fair figure as a basis of evaluation of all kinds of coals and is impartial to the various methods of cleaning coal. It is uniform with the generally accepted standard for blast-furnace coke, which is 90% fixed C (at 212° F.) and 3% moisture, equivalent to 87.3% fixed C in the coke as received. The steel industry has the most to gain from coal cleaning as the benefits that accrue are pyramided in steel making. It is calculated that 1% ash in 10 coking coal adds 30¢/ton of pig-Fe to the cost of pig-Fe made by the coke from that coal. Coal cleaning is of especial importance to the Pittsburgh steel industry, because it will lead to lower operating costs, and thus enable Pittsburgh to meet the competition of other favorably located steel producing districts. MS (23)

The Use of Gas as a Fuel in Industry. C. M. WALTER. *Gas World,* Vol. 96, June 11, 1932, pages 611-614; Vol. 97, June 18, 1932, Industrial Gas Supplement, pages 10-20.

Includes discussion. The paper covers the following subjects: metal melting, japanning and drying operations, forging, central heating, economic value of gas as a fuel, coke oven gas, application of town's gas to high speed internal combustion engines, experiments carried out at Birmingham, the results of these tests and the percentage of CO in exhaust gases. The author's conclusions are: (1) The thermal efficiency of high speed internal combustion engines when supercharged is greater when using town's gas than when gasoline is used, and is further increased by carburetting the gas with benzol. (2) The thermal efficiency with gasoline as a fuel is decreased by the application of supercharging. (3) The maximum power developed with gas alone is lower than that obtained with gasoline. (4) The CO content of the exhaust gases is considerably less with town's gas as a fuel than in the case of gasoline. (5) Gas is more responsive to supercharging than gasoline, the power output being increased to a greater extent. In the tests with supercharging, the thermal efficiency was only decreased by 0.25% on town's gas, compared with 6.45% on gasoline. (6) The thermal efficiency obtained with town's gas would be further improved by increasing the compression ratio. (7) The performance of the engine is much improved by saturating the gas with benzine or benzol, the amount of the benzine required being about ¾ gal./1000 ft.³ of gas. MAB (23)

The Use of Gas as a Fuel in Industry. *Gas World,* Vol. 97, July 16, 1932, Industrial Gas Supplement, pages 9-10.

The article consists of written contributions to the discussion on C. M. Walter's paper, presented at the annual meeting of the Institution of Gas Engineers (see preceding abstract). P. Lloyd discussed the concept of furnace efficiency; C. S. Shapley, the question of fuel cost; H. J. Toogood, the cheapest British fuel; Walter replied to all these discussions. MAB (23)

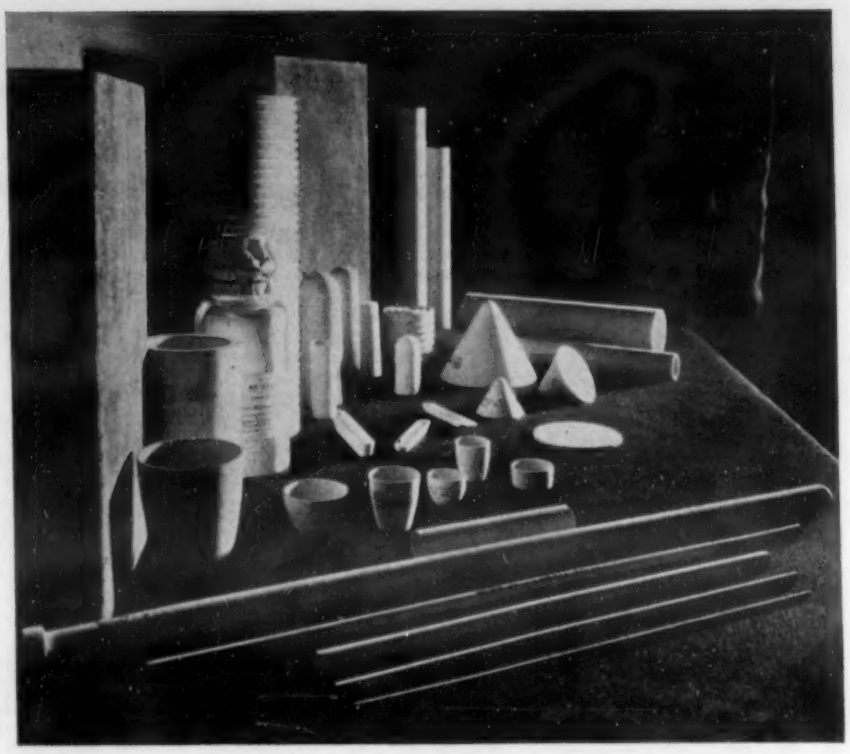
Recent Developments in Gas Burners. Part IV. W. TRINKS. *Heat Treating & Forging,* Vol. 18, May 1932, pages 319-320, 322; *Blast Furnace & Steel Plant,* Vol. 20, May 1932, pages 436-438.

Discusses the design of luminous-flame burners. MS (23)

Progress in the Industrial Application of Gas. (Fortschritte der industriellen Gasverwendung.) OTTO WOLFF. *Gas und Wasserfach,* Vol. 75, July 30, 1932, pages 617-623.

Paper read before the 73rd annual meeting of the Deutscher Verein von Gas und Wasserfachmännern, May 30, 1932, at Essen. The manifold applications of gas for heating purposes in the ferrous and non-ferrous industry are presented in detail and the recent increase in the thermal efficiency of gas heated furnaces is shown. Some new types of furnaces, such as a bright annealing furnace, system Prüfert, rotating soldering furnaces, etc., are described. The efficiency of gas heating is illustrated in the case of a crucible melting plant for brass and bronze. 5 references. GN (23)

Furnace Chamber Studies of a 200-ton Open-hearth Furnace Heated with Mixed Gas. (Kammer Untersuchungen an einem mit Mischgas Beheizten 200-t-Siemens-Martin-Ofen.) KURT HÜBNER. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 591-601.



Report 229 of Steel Mill Committee of Verein deutscher Eisenhüttenleute. Includes discussion, 14 references and 11 tables of data. A 200-ton open-hearth tilting furnace fired with a mixture of coke-oven and blast-furnace gas was studied as to pressure loss, flue gas distribution, leakage air admission, heat loss and preheating, with a heat balance both for gas and air chambers and ducts. Average analyses are given of fuel, combustion, air chamber, gas chamber, and flue gases. The use of an insulating material "Sterchamol" for improving heat efficiency gave good results for the gas chamber but the air chamber walls, arch and ducts require no costly Sterchamol insulation. The design of the air and gas chambers was made in accordance with specifications of an experimental chamber at the Ruhrort-Meiderich Works. Good practice in construction of regenerator chambers of open-hearth units using mixed gas fuel is discussed thoroughly. DTR (23)

Efficient Forge Furnace. C. FOSTER CLARK. *Heat Treating & Forging,* Vol. 18, June 1932, pages 371-372.

A conventional type furnace has gas burners placed 2 to a side and inclined so that their axes are practically tangential to the arch. Center line of burners on one side is placed 3″ below center line of opposite burners. Center lines of burners are staggered in the horizontal plane also. Tunnel-type burners with alloy tips are used. Burner nearest the slot on each side is drilled with a 1″ nozzle, while rear burners are drilled ⅞″. A low-pressure inspirator supplies each pair of burners with mixture of air and gas. A flue is built on each side in such a way that gases are drawn from the level of the hearth rather than from the arch. Furnace is equipped with a motor-driven temperature-control valve. Furnace is designed to heat about 300 lb./hr. of ⅞″ round and square sections of a special steel similar to SAE 1015. At maximum capacity, 130 lb. of steel are heated/ft.² hearth area/hour. In regular production work, it has averaged 3.3 ft.³ of 530 B.t.u. gas/lb. stock. It has increased production 25% above that of oil-fired furnaces of the same size operating on the same material. Life of forging dies has been increased about 40%, burnt stock has been eliminated, there is quicker heating from cold, and uniformity of heat. In 2 years, the only maintenance work has been the replacement of about 1/3 of the lining. A slightly oxidizing atmosphere is maintained. MS (23)

Advancements in Industrial Furnace Construction. (Neuerungen im Industrieofenbau.) *Die Wärme,* Vol. 55, Mar. 26, 1932, pages 214-215.

Some erroneous designs of gas and oil fired industrial furnaces are critically discussed. A single burner muffle furnace of 0.9 × 1.8 × 0.4 m. inside dimensions, and a hardening furnace for high-speed steels are described and illustrated. In these the material does not come in contact with the flame; the furnace roof and walls reverberate the heat and heat the charge by radiation. EF (23)

How is your stock of LABORATORY WARE?

For Ignition
Incineration
Filtration

ALUNDUM Laboratory Ware is characteristically strong, has high heat transfer properties and long life. Cleaning is a simple process of washing and igniting to constant weight.

There are tubes, cores and muffles for electric furnaces. Crucibles and dishes for igniting, incinerating and melting.

Dishes, cones, discs, thimbles and crucibles for filtering. Combustion boats, pyrometer tubes and refractory cements.

A great variety of standard sizes and shapes are carried in stock for immediate shipment.

A catalog describing Norton Laboratory Ware will be sent upon request—no obligation.

ORE CONCENTRATION (33)

Concentration of the Rake Discharge from a Bowl Classifier in a Washing Plant of the Mesabi Range, Minnesota. Fred D. DeVaney & Will H. Coghill. *United States Bureau of Mines, Report of Investigations* No. 3148, Apr. 1932, 7 pages.

Fines from ores of the jigging type are readily concentratable by classification and tabling. Bowl rake products containing 14-20% SiO_2 are even more amenable to treatment. From such material a large % of the Fe can be recovered direct from the first spigots of a classifier; only the later spigots require tabling. From rake products containing 20% of SiO_2, approximately 45% would be recoverable as classifier concentrates; at the overflow end 5% can be discarded, leaving 50% to be tabled. From a table feed assaying Fe 44.40%, insoluble 34.50%, and SiO_2 33.68%, concentrate was produced assaying Fe 62.98%, in soluble 9.00%, and SiO_2 8.00% and a tailing of Fe 21.32%, insoluble 67.42%, and SiO_2 65.15%. The concentrate carried 79.78% of the total Fe and the tailing 84.17% of the insoluble. AHE (33)

Methods and Costs of Concentrating Scheelite Ore at the Silver Dike Mill, Mineral County, Nevada. William O. Vanderburg. *United States Bureau of Mines, Information Circular* No. 6604, Apr. 1932, 12 pages.

An ore containing 1% of scheelite is tabled. The concentrates are roasted and then cleaned magnetically to give a final concentrate containing 70-75% WO_3 with an 80-81% recovery at a total direct cost (details given) of $2.649/ton of ore. Flotation experiments using in roughing pine oil 0.12 lb., oleic acid 0.16 lb., Na oleate 0.40 lb. and Na_2CO_3 0.75 lb. and in cleaning Na_2CO_3 0.75 lb. and Na silicate 0.40 lb./ton of ore gave a concentrate (3.4%), middling (21.7%) and tailing (74.9%) assaying 62.72%, 1.03% and 0.03% WO_3, respectively, for recoveries of 89.7%, 9.4%, 0.9% of the WO_3 in the 3 fractions. Concentrates up to 79% WO_3 have been obtained at only slightly less recovery. AHE (33)

Progress in Metal Mining in Manitoba. George E. Cole (Director of Mines, Manitoba). *Canadian Mining & Metallurgical Bulletin* No. 238, Feb. 1932, pages 39-57.

Flotation, cyanidation, leaching and Cu smelting at Flin Flon and milling methods at Sherritt Gordon are described. AHE (33)

Flotation (33c)

Milling Methods at the Concentrator of the Walker Mining Co., Walkermine, California. M. R. McKenzie & H. K. Lancaster. *United States Bureau of Mines, Information Circular* No. 6555, Mar. 1932, 11 pages.

A Au- and Ag-bearing chalcopyrite-magnetite-quartz ore assaying (average for 6 mo., 1930) Cu 1.687%, Fe 9.0%, S 2.1%, CaO 1.1%, insoluble 79.2%, Au 0.05 oz. and Ag 0.833 oz./ton is concentrated by flotation to give concentrates (6.41%) assaying Cu 24.00%, Fe 22.1%, insoluble 14.5%, Au 0.49 oz. and Ag 9.920 oz./ton and tailings (93.59%) containing Cu 0.163%, Fe 8.1%, insoluble 83.5%, Au 0.02 oz. and Ag 0.200 oz./ton. Recoveries were Cu 91.2%, Au 62.7%, and Ag 73.3%; the tailings carry 98.8% of the insoluble. Consumption of flotation reagents was lime 1.40 lbs., pine oil 0.321 lb., K eethyl xanthate 0.084 lb. and Na aerofloat 0.075 lb./ton of ore. AHE (33c)

Flotation Tests on Lead-Silver Ore from the Mallard Lake Gold Mines, Ltd., Kirkland Lake, Ontario. J. S. Godard. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 3-4.

A low-grade Pb-Ag ore of chalcopyrite and sphalerite in calcite and assaying Au 0.02 oz. and Ag 6.40 oz./ton., Pb 5.70%, Cu 0.47% and Zn 0.49% gave recoveries by flotation of Pb 97% and Ag 94% in a concentrate assaying Pb 65%, Cu 4.81%, Zn 2.13%, Ag 68 oz. and Au 0.15 oz./ton using soda ash, cyanide, thiocarbanilide and pine oil. AHE (33c)

Salts in Tri-State Mill Waters: Their Ill-Effect on the Flotation of Blende and Their Removal. A. B. Campbell, Warren Howes & W. H. Ode. *United States Bureau of Mines, Report of Investigations* 3149, Mar. 1932, 24 pages.

The use of acid mine waters for milling purposes in the Tri-State Zn district of Mo., Kan., and Okla. has resulted in corrosion of mill equipment and difficulties in the flotation operations. The acid waters were most abundant in the eastern part of the Picher district, where carbonates were absent in the ore bodies. If carbonates, chiefly calcite, were found in the tailings piles the waters did not contain enough acid or metallic salts to cause trouble. Analyses of the troublesome waters sometimes showed more than 5000 p.p.m. of free acid and of dissolved salts in the form of sulphates. The principal corrosive agents are free acid and $Fe_2(SO_4)_3$. The principal flotation toxic is $FeSO_4$; $ZnSO_4$ requires minor consideration. Appreciable quantities of the sulphates of Ca and Mg caused little or no trouble. The most satisfactory treatment is the selective removal of the ferrous and ferric Fe and free acid by alternate periods of aeration and neutralization. The aeration oxidizes the ferrous Fe: the neutralization removes free acid and the ferric Fe. Neutralization may be accomplished most cheaply by upward percolation through high-grade limestone; low-grade limestones are ineffective. Bases, such as lime and caustic soda, act more quickly, but their cost is higher. AHE (33c)

The Differential Flotation of Copper and Iron Sulphides in the Ore of the Aldermac Mines, Ltd., Aldermac, Quebec. A. K. Anderson, J. S. Godard & C. S. Parsons. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 101-110.

An ore of pyrite and pyrrhotite with small amounts of chalcopyrite assaying Cu 1.75%, Fe 28.2%, and S 39.3% was floated easily. To secure maximum recoveries a low-grade rougher concentrate is produced and cleaned. The Cu minerals were sensitive to cyanide; if over 0.04 lb. cyanide per ton is added the Cu is depressed. Recoveries fall off when grinding exceeds 65% solids. Typical results show 93.6% Cu recovery in a rougher concentrate assaying 20.72% Cu and 63.2% of the mill feed recovered as pyrite concentrate assaying 52.2% S using reagents as follows, in lb./ton of ore: ball mill — soda ash 3.7, cyanide 0.035, Aerofloat No. 25 0.06; Cu cells — cresylic acid 0.036; Fe cells — soda ash 2.1, Aerofloat No. 25 0.09, $CuSO_4$ 0.5, K xanthate 0.66. The ball mill discharge was 58% solids. AHE (33c)

Mineral Flotation. A. F. Taggart. *Journal Physical Chemistry*, Vol. 36, Jan. 1932, pages 130-154.

The mechanism of flotation of sulphide ores is discussed from a physical chemical standpoint. In froth flotation the material removed is lifted by the bubbles, probably at the oil-water interface. Relatively large droplets of Nujol observed under a magnification of 20x to 30x, upon adding a frothing oil, entrained air and a larger quantity of solid was carried probably at the oil-water interface. A useful frothing reagent should lower the surface tension at the air-liquid interface from 3 to 5 dynes/cm. The effectiveness of H_2SO_4 and similar inorganic frothing reagents probably is due to the liberation of organic frothing agents from the film of oil and grease naturally present in the ground ore. The best frothing agents are slightly soluble organic compounds, characterized by a hydrocarbon group of relatively high molecular weight carrying an O_2-bearing polar group. An average of 5.5 C atoms, with the following polar groups (in order of decreasing frequency of occurrence), are good frothers: OH, CO, COOH, CONH, COO and COC, and with solubility around 1000 mg./l. Essential oils with high percentages of terpineol, menthol, eucalyptol, borneol, camphor and the like, are the best frothers. The solid-loaded films in froth flotation are enormously more stable than films produced with the same reagents but with no solids present. Straight hydrocarbon oils serve as "collectors" increasing the amount of solid floated although xanthates are the modern collectors. The action of oils as collectors is based upon the hypothesis that the oil-sulphide interfacial energy is less than that of the water-sulphide interface while for quartz the reverse must be true. In other words, the oil wets the ore. The chemical collectors are characterized by a multi-valent amphoteric element, combined in a low valent or reduced state (hence capable of reacting with the surface of the substance to be floated). A reasonably bulky hydrocarbon portion, 7-8 atoms, is usually necessary. Besides the xanthates, compounds containing the following groups are also effective: amino, amide and thioamide, azo and diazo, sulphide and sulph-hydrate. Besides the frothing and collecting agents conditioning agents must be used. These act in one of 5 ways, viz: (1) By reacting with the surface of the mineral to be floated so as to increase its floating tendency, (2) to decrease the floating tendency of some constituent, (3) to react with and remove some undesirable salt from the solution, (4) to increase the degree of dispersion thus modifying the effect of the slime upon the particles to be floated, (5) to maintain the pH at the proper point. The methods are discussed with a brief classification of the types of machinery used. WHK (33c)

Flotation. (Flotation.) Erwin W. Mayer & Hubert Schranz. S. Hirzel, Leipzig, 1931. Cloth, 6 x 9 inches, 593 pages. Price 35 RM.

This book is a comprehensive survey of the art of flotation in its present day status.

Periodical literature, technical society transactions, university research publications, patent literature and trade publications have been covered thoroughly, freely referred to and annotated so as to furnish an up-to-date bibliography of the subject.

The first section of the book covers the definition, description, variations and limitations of flotation together with the history of the art and its general applications supported by world statistics.

The second section deals with ore dressing and flotation equipment, including excellent illustrations and descriptions supported with considerable operating data of equipment in use in present day practice.

The third section discusses modern flotation processes and the theories that have been advanced to explain them; also the control of the process including the influence of slime density, temperature, H ion concentration. Fifty-two pages are devoted to flotation reagents.

A fourth section treats individual applications of simple and selective flotation to an extensive list of ores, also to oxidized ores and minerals including a special section on coal flotation.

Only two pages are devoted to research apparatus which seems rather deplorable in a text otherwise so practical, and particularly in an art which owes much of its development to intensive test work.

Considerable cost data, process data assembled in charts, flowsheets, list of German patents, list of ores, minerals mining and milling terms with corresponding English equivalents and a bibliography of recent important articles on flotation form a valuable appendix. H. Earl Dunn (33c)-B-

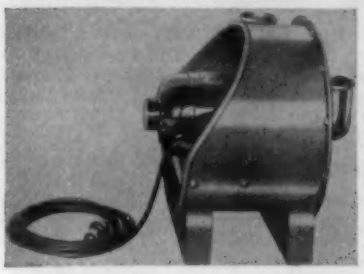
Physical Chemistry in Relation to Separation of Ores. Julius Grant. *Crushing & Grinding*, Vol. 1, Mar.-Apr. 1932, pages 134-135.

Principal factors in froth flotation are: (1) surface tension of the medium, (2) size of particle, (3) agitation and the tendencies of the system towards coagulation or adsorption, (4) foreign substances, and (5) pH. Flotation phenomena may be explained electrically. These points are discussed.

Magnetic Separation (33d)

AHE (33c)

The Laboratory Concentration of Bell Iron Ore. T. W. Hardy & H. H. Bleakney. *Canada Department of Mines, Mines Branch, Report* No. 724, 1932, pages 198-200.



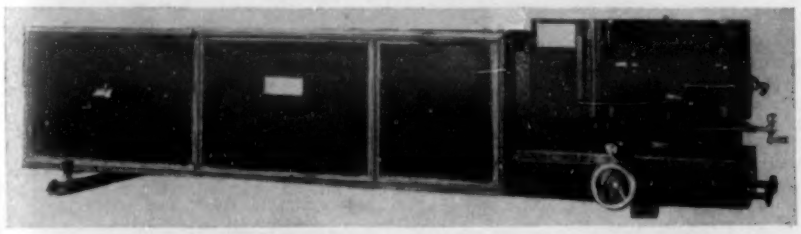
Magnetic concentration rejected 60% of the insoluble at minus 20 mesh and 77% at minus 200 mesh. In commercial practice the sponge Fe should contain 80-85% Fe. AHE (33d)

Theoretical Principles of the Fine-Crushing of Ores. (Theoretische Grundlagen der Feinzerkleinerung von Erzen.) P. Erimesco. *Zeitschrift Verein Deutscher Ingenieure*, Vol. 76, Jan. 30, 1932, pages 115-117.

For each kind of concentration there exists an optimum grain size to which the ore must be reduced; this is particularly important for an economic and thorough extraction of poorer ores as they have to be worked today after exhaustion of rich deposits. The physical foundations of the methods for crushing are discussed, crushing resistance and a scale to measure it are explained. The machines used at present do not yet conform to scientific operation; the author recommends more detailed study of the process. 5 references. Ha (33e)

New Equipment and Materials

Small Turbo Air Compressor



The smallest multi-stage centrifugal compressor ever built for commercial purposes by the Spencer Turbine Company of Hartford, Conn., is now in standard production. This unit is self-contained, and will deliver 75 cu. ft. of air per minute at 12 oz. pressure. It is 12 in. in diameter and weighs 40 lbs. The motor is 1/3 H.P. a.c. or d.c. This Spencer Turbo Compressor is used for individual operation of all forms of heat treating equipment, gas boosters and other devices requiring low pressure air.
Metals & Alloys, April 1933.

Temperature Control Device

"Anticipatory" control action may be obtained with any pyrometer controller, it is said, by adding a new auxiliary device developed by the Foxboro Company of Foxboro, Mass. This action is said to eliminate hunting or over-controlling. The Deoscillator is cut-in between the thermocouple and the controller. In operation, the instrument impresses into the thermocouple circuit a slight additional e. m. f. that augments the thermocouple e. m. f. when the temperature is low and opposes it when the temperature is high. This causes the controller to close either the high or low circuit a little ahead of the actual temperature demand. The effect prevents excessive overrun or underrun. Adjustment to the requirements of the particular heating equipment on which the Deoscillator is installed is quickly made. Once the instrument is set correctly, that setting will hold for practically any condition from no load to full load.
Metals & Alloys, April 1933.

Large Littrow Spectrograph

The new Bausch & Lomb Optical Co. Littrow type spectrograph was intended for the analysis of materials yielding extremely complicated spectra. It was necessary to build an instrument of large size, in order to secure the necessary separation of lines on the photographic plate, so that even the most complex spectra are effectively resolved and dispersed. This permits accurate work, both qualitative and quantitative, with alloy steel, tungsten carbide alloys, stellite and other materials yielding spectra in which the lines are crowded together.

Its characteristic feature is the use of a reflecting surface on the back of the prism to reflect the dispersed light back through the prism and lens, the latter serving both to collimate the entering light and to focus dispersed spectrum on the photographic plate. This makes it possible to build an instrument half the length necessary to get an equivalent distance between the slit and the photographic plate and requires but half the amount of expensive optical quartz. This spectrograph is of heavy, rugged construction to insure rigidity and permanence of alignment and adjustment.

A glass optical system is available, interchangeable with the quartz, which gives a still wider separation of lines between 3550 and 8000 A.U. It will be found particularly useful for studies in the visual portion of the spectrum, in which lie the most important lines of the alkalies, the alkaline earths and a few other elements. This portion of the spectrum will cover 2 ten inch plates.

A complete series of adjustments permits change in slit width, slit length, position of the spectrum on the plate, angle of the plate with the light beam, etc.

The entire mechanism, of unusually large proportion, is enclosed in a case of sheet metal. This large size has been found to be the most effective means of providing for the deflection and absorption of stray reflected light, insuring clean plates free from the fog and light streaks.
Metals & Alloys, April 1933.

Testing Machine Recorder Controller

Several devices, distinct from one another and associated for the purpose for the first time, provide in alternative combinations (1) an autographic stress-strain recorder which produces a graph up to incipient failure, or which may, by adaptation, produce a graph to and through failure on metal, wood or any other material; (2) an instrument which is all of (1) and in addition controls load application to effect constant rate of strain increment, constant rate of load increase and load maintenance at constant value. The new apparatus, brought out by Baldwin Southwark Corp., Philadelphia, Pa., in no way limits manual control; such control is inherent up to any predetermined point at which the instrument takes over the control function and proceeds to exercise it to a point elected by the operator. The devices are combinations of (1) extensometers, (2) Bourdon tube, and (3) hydraulic valves in association with motors, relays, solenoids and mechanical clutches. The extensometer or strain gage is fundamentally a micrometer screw in combination with a mechanical lever multiplying system. (See Fig. 1.) It is not primarily an indicating instrument, but a relay—a link between the varying gage length and the recording pencil. As the specimen extends (or contracts) an electrical circuit is broken. The recorder proceeds at once to re-establish the circuit by turning the micrometer screw until a new contact is made. Action at once ceases. But this effort of the recorder to re-establish a broken circuit serves as the means of moving the recorder pencil by the proper amount to record the strain variation. The sensitivity is to 0.00002 in. strain. The accuracy is ± 0.00005 in.

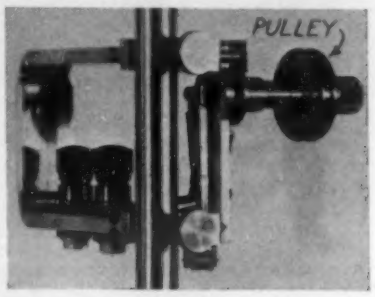


Fig. 1

Fig. 2

A precision Bourdon tube pressure-measuring element, incorporated in the stress-strain recorder-controller (Fig. 2), operates a light metallic arm on the end of which is a coiled nickel wire having a "cat whisker" making light contact with silver segments. The circuit thus opened and closed (without affecting the Bourdon tube) includes a sensitive relay which controls the mechanism for rotating the recording drum (which carries the graph paper) in strict proportion to the movement of the arm, which movement, in turn, is in strict proportion to the load on the specimen under test. Through a similar relay method, the recording pencil is positively driven in strict proportion to the variation in strain. Multiplication ratios of as much as 2000 may be had. It is found, however, that a multiplication ratio of 250 to 750 provides greater all-around satisfaction. These parts are essentially those of the recorder alone. They also are integral parts of the recorder-controller which not only makes a record but also controls the *time-rate* of application of stress or strain at the command of the operator. 12 speeds are available: 6 on an inches-per-minute basis and 6 on an inches-per-hour basis. (In other terms, speeds from 0.0001 in. per inch gage length per hour to 0.002 in. per inch gage length per minute.) The number of steps may be indefinitely extended by the multiplication of sets of change gears. The *strain* in the specimen (which means movement of the ram in the load-production cylinder of the testing machine is controlled as to time-rate by the quantity of fluid admitted to this cylinder. In like manner, an auxiliary disk is driven by a synchronous motor at various desired velocities and contacts serve to control the time-rate of *stress* application. Speeds of stress application to one-half the capacity of the testing machine per minute are available. In both rate-of-strain and rate-of-stress control, slippage of the specimen in the grips, of the grips in the heads of the testing machines, and strain outside the gage length of the specimen, have no effect on the controlled rate of strain or stress application. It is possible, also, to produce strain-time or stress-time graphs by availing of the synchronous motor motions. The devices represent a step forward in the field of materials testing for it has never before been possible to control automatically and within narrow limits, rates of strain and stress application. With some non-ferrous materials, these rates are of vital importance in the interpretation of test results.
Metals & Alloys, April 1933.

MANUFACTURERS' LITERATURE REVIEWS

68 **Beryllium Copper**—A most attractive booklet has recently been published by the Riverside Metal Co., Riverside, N. J., which presents briefly general information on Beryllium Copper, its composition, general properties, heat treatment and gives a number of suggested applications for this alloy.

69 **Non-Ferrous Spekker**—Adam Hilger, Ltd., London, England, have published a pamphlet describing their spectroscope for the rapid estimation of metallic elements in non-ferrous metals. Directions for its use are given. Publication No. 173/2 of the same company discusses their X-ray metallurgical crystallograph for the X-ray examination of the effects of heat and mechanical treatment on metals.

70 **Optical Instruments**—Catalog L-1 of the Gaertner Scientific Corporation, Chicago, Ill., illustrates and describes their spectroscopic instruments and accessories.

71 **Nickel Cast Iron Data**—The International Nickel Company, New York, N. Y., has published a data sheet designed as a convenient and quick source from which suitable nickel and nickel-chromium cast iron compositions may be selected for specification purposes. Supplementary sheets devoted to specific applications, such as dies, brake drums, grate bars, etc., will be issued.

72 **Saving on Carboloy Tools**—In a folder recently issued by the Carboloy Co., Detroit, Mich., the suggestion is made that the user purchase his Carboloy tools "milled and brazed" and so effect a substantial saving on every order. The only difference between "milled and brazed" tools and regular finished tools is that they have not been ground.

73 **Relays for Laboratory and Industrial Use**—A 4-page bulletin on supersensitive, mercury, mechanical and photoelectric relays for a wide variety of control applications has recently been issued as Bulletin No. 1001 by the American Instrument Co., Washington, D. C.

74 **"The Laboratory"**—A recent issue of this publication of the Fisher Scientific Co., Pittsburgh, Pa., features an interesting article on The Evolution of Weights. A new burette holder is described in a brief article and a new acoustimeter is illustrated.

75 **X-Ray of Code Welds**—The Kelley-Koett Mfg. Co., Covington, Ky., is distributing reprints of an article by this title which describes the X-ray examination of welds for areas of incomplete fusion, gas pockets, slag inclusions, etc.

76 **Welding Electrodes**—The Bannar Welding Supply Co., 156 Main St., Buffalo, N. Y., has sent out a leaflet describing the Nico welding electrodes distributed by them. Mention is also made of their copper-arc electrodes and suggestions are given for welding cast iron having excessive free carbon.

77 **Midget Air Grinder**—A new air grinder, small enough to be concealed in the palm of the hand, yet having a tested grinding speed of 40,000 revolutions per minute has just been announced by the Madison-Kipp Corporation, Madison, Wis. The line contains models for every service requiring wheels up to 1½" in diameter.

78 **Carborundum**—The Carborundum Co., Niagara Falls, N. Y., has prepared an attractive booklet entitled "Products of the Carborundum Company that Serve the Steel Industry." It describes their Aloxite Brand Redmanol Wheel for foundry grinding, their "Green Grit" wheels for grinding tungsten carbide, their Aloxite "TP" polishing grain and their "Carbofrax" hearths.

79 **Darkfield Microscopy**—Bulletin No. 4 of E. Leitz, Inc., 60 East 10th St., New York N. Y., discusses briefly their darkfield microscopy for micro analysis of metals. Several micrograms in darkfield and brightfield are reproduced and contrasted.

80 **Alloy Steels**—A series of leaflets has been issued by the Wheelock, Lovejoy & Co., Inc., New York, N. Y., each leaflet being devoted to a particular analysis of alloy steel. The physical properties, heat treatment, composition and outstanding characteristics of each are given. The leaflets are punched for filing in a pocket notebook.

81 **Moisture Tester**—A leaflet devoted to the "Speedy" Moisture Tester marketed by them has been issued by the Alpha-Lux Co., Inc., New York, N. Y. Its use in the testing of molding sand is emphasized, though it can be used for coal, coke, abrasives, paper, cotton, grain, etc., as well.

82 **Nichrome**—Booklet R-28 of the Driver-Harris Co., Harrison, N. J., contains data and specifications pertaining to alloys for electrical resistance with detailed discussion of Nichrome, for use in heating devices operating up to 900° C. (1652° F.), and Nichrome IV, which resists oxidation at temperatures up to 1150° C. (2102° F.).

83 **Metallic Zinc Paint**—A booklet recently issued by the American Zinc Institute, New York, N. Y., stresses the use of metallic zinc paint for the protection of metal surfaces against corrosion. The composition, manufacture and properties of this paint are given, together with suggestions for its use.

84 **Desulphurizing Cast Iron**—The Mathieson Alkali Works, New York, N. Y., is distributing rotoprint copies of "Desulphurizing Cast Iron—An Outline of the Different Methods of Refining Cupola Metal with Purite" which was prepared by George S. Evans, metallurgist. It is a complete and detailed discussion of the process.

85 **Projection Welding**—A new folder of P. R. Mallory & Co., Indianapolis, Ind., entitled "New Light for Old," describes their alloy of copper and tungsten "Elkonite" in relation to projection welding, a new process by which many welds can be made at one operation. Their folder "Mushrooms" is devoted to their water-cooled holders and "Elkonite" as an electrode die material.

86 **Carburizing Compound**—A booklet prepared by the Char Products Co., Merchants Bank Building, Indianapolis, Ind., describes their case hardening material which is said to effect great economies in the carburizing of steel. It is manufactured in three types to meet individual requirements.

87 **The Romance of Electrical Contacts**—A 42-page book sent out by P. R. Mallory & Co., 350 Madison Ave., New York, N. Y., describes the development of their platinum, tungsten and silver contacts. A chapter is devoted to the sizes of the various forms of contact points.

88 **The Zinc Alloy Pot**—The second issue of this publication of the New Jersey Zinc Co., New York, N. Y., contains a summary of the analysis of the answers received from a nation-wide questionnaire covering the status and trend in metal product development. There is also a cost analysis of machined castings vs. die castings and a table of casting limits for various alloys.

89 **Welding**—An attractive little 36-page book entitled "The Romance of Resistance Welding" has been issued by Elkon, Inc., Division of P. R. Mallory & Co., Indianapolis, Ind. It describes the early development of Elkonite and its applications at present. A folder sent out by the same company called "A Miss is as Bad as a Mile" describes their water-cooled welding tips.

90 **Atmosphere Furnaces**—A recent circular sent out by the Surface Combustion Corporation, Toledo, Ohio, gives performance data on their atmosphere furnaces which have been compiled from installations in actual production on bright annealing, carburizing and nitriding.

91 **Welded Tubing**—The Carpenter Steel Co., 100 Broadway, New York, N. Y., has issued a leaflet which gives the physical properties and working instructions for their stainless welded tubing.

92 **Electric Furnaces**—Bulletin No. 280 of H. O. Swoboda, Inc., Pittsburgh, Pa., shows diagrams and illustrations of the "Falcon" electric heat treating equipment. The layout for a complete hardening and tempering installation is given.

GENERAL (0)

Journal of the Institute of Metals, Proceedings. Vol. 48, No. 1, 1932. Cloth, 5½ x 8½ inches, 350 pages.

This volume contains the minutes of the 24th annual general meeting of the Institute held in March 1932, together with the papers read at that meeting and the discussion. These papers have been abstracted individually in *Metals & Alloys.* M. L. Moorman (0)-B-

General Engineering Handbook. C. E. O'ROURKE. McGraw-Hill Book Co., New York, 1932. Cloth, 5 x 8 inches, 921 pages. Price $4.00.

This is an attempt to summarize fundamental data for all branches of engineering into one handbook.

The metallurgical aspects of the book would have been improved had the long list of assistant editors included a metallurgist. Endurance properties get no direct mention, though a few tables copied from H. F. Moore include endurance data. Nothing is said about the effect of notches. Not only are nitriding and chromium plating not mentioned, but the reference to carburizing would not indicate to the reader what case carburizing is good for.

High test cast iron is barely mentioned. Nickel iron is included, but the reader would assume that it was always used alone, without chromium and that there were no other alloying elements available. Alloy steel is nearly as poorly treated. High speed steel is not mentioned, to say nothing of tungsten carbide. Machining and machinability are evidently considered not fundamental in engineering.

The discussion on bearing metals is not of much metallurgical moment.

It is stated in sec. 28, written by a professor at M. I. T., that a thermocouple of 90% platinum 10% *rubidium* is suitable up to 1500° C.

The section on welding is about the only one in which any symptom of real metallurgical knowledge is indicated.

The book is written by civil engineers and is a civil engineering handbook plus a little more, but the little more includes a vanishingly small amount of metallurgical information. H. W. Gillett (0)-B-

Replacing Metals by Synthetic Resins—Phenol-Resinoid Molding Technique. LEON V. QUIGLEY. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, *Machine Shop Practice,* pages 17-28.

The mechanical properties of synthetic resins with a phenol base are described and their suitability for replacing metals discussed. The many fields in engineering practice where they are employed are illustrated. Ha (0)

Metallography and Its Place in Industry. J. R. MILLER. *Heat Treating & Forging,* Vol. 18, Jan. 1932, pages 57-60.

Points out that the metallographist should be exceptionally well grounded in all branches of metallurgy and in chemistry and physics, and should have an intimate familiarity with technique. Discusses briefly some methods which may be used in the future. Counsels against premature application of unfinished theories to practical inspection work. Reports of research work should contain complete information. MS (0)

Definition of Dividing Line Between Steels and Cast Irons. A. L. NORBURY. *Metallurgist,* Jan. 1932, page 16.

A letter to the editor in which the following definitions for cast irons and steels are advocated. "——— cast irons are those Fe-C alloys which contain carbide eutectic, or graphite eutectic, in the as-cast condition, while steels are those which do not contain such eutectic." In the Feb. 1932, issue of the *Metallurgist,* pages 17-18, this letter is discussed to the effect that under modern conditions a satisfactory line of demarkation between steel and cast Fe is not feasible if the definitions involved are to be strictly applicable to all cases. For the broad distinctions which apply to most uses of these terms, the generally understood meanings attached to them are no doubt sufficient. Where exact or more or less legal terminology is needed, the *Metallurgist* suggests that specification of the nature and range of the material involved in each case should be employed in place of such general terms as "cast iron" and "steel." VVK (0)

Coöperative Research in the Iron & Steel Industry. F. N. SPELLER. *Year Book of the American Iron & Steel Institute.* 1931. pages 48-79.

See *Metals & Alloys,* Vol. 2, Sept. 1931, page 159. (0)

The Theory of Metallurgical Processes. CH. K. AVETISSIAN. *Tzvetnuie Metallui,* Oct. 1931, pages 1311-1329.

A theoretical discussion of methods of investigation of metallurgical processes and the application of thermodynamics to the study of steel making and Cu smelting processes. BND (0)

Some Principles of Testing. W. ROSENHAIN. *Metallurgist,* Apr. 1932, pages 57-58; May 1932, pages 71-72.

Testing of metals and alloys should be the testing of the true physical constants. Our knowledge of the behavior of metals under stress is not sufficient to permit of more than an approximation or compromise. Metals are therefore tested under service conditions and, from the information gained, we can endeavor to determine these constants. Ideal fundamental considerations must be kept in the forefront. VVK (0)

Teaching and Research in the Foundry Institute of the Technical University of Aachen. (Lehre und Forschung im Giessereiinstitut der Technischen Hochschule zu Aachen.) E. PIWOWARSKY. *Die Giesserei,* Vol. 19, July 8, 1932, pages 262-269.

An exhaustive review of the work done during the last 4 years in the fields of cast Fe, hard castings, malleable Fe, steel castings and non-ferrous metal casting. Many diagrams represent the behavior of the metals. 35 references. Ha (0)

Utilizing the Testing of Materials for Construction. (Die Nutzbarmachung der Werkstofforschung für die Konstruktion.) E. LEHR. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 333-337.

Emphasizes the importance of intelligent engineering interpretation of test results. Unless the test exactly duplicates service, a factor of safety is required. HWG (0)

The National Physical Laboratory. *Engineering,* Vol. 134, Aug. 12, 1932, pages 190-192.

A summary of the various metallurgical investigations recently carried out at the Laboratory. Research has been along the following lines: X-ray analysis, high-purity metals, refractories; analysis of steel and cast Fe, standard samples; Al, Mg, Be; materials for use at high temperatures; alloys of Fe, impurities in Cu, dental amalgams; viscosity. LFM (0)

Process Control and Removal of Defects by Means of Large Scale Research. (Betriebsüberwachung und Fehlerbeseitigung durch Grosszahl-Forschung.) KARL DAEVES. *Stahl und Eisen,* Vol. 52, July 28, 1932, pages 725-729.

Report 183 of Committee on Materials of Verein deutscher Eisenhüttenleute. A general discussion of the value of research work on process control and uniformity of production. For any industry the writer suggests the use of frequency curves in each phase of production. These frequency curves may tell at a glance just what difficulties are to be expected, the magnitude of each defect, and naturally which defect is most likely to be controlled or eliminated. Relations may be derived also between measurable factors in production and good production or scrap. In industrial research it is not alone sufficient to use a definite, statistical, physical or chemical method. It is also highly desirable to apply all other methods for a problem in order to arrive at economy and improvement in process and material. DTR (0)

Steel and Its Practical Applications. WILLIAM BARR & A. J. K. HONEYMAN. Blackie & Son, Ltd., Glasgow, 1932. Cloth 5¼ x 7½ inches, 125 pages. Price 6s.

A very elementary treatise in 13 chapters. The general character of the subject matter and treatment is indicated by the following discussion of a few chapters. Chap. I, "The Preparation of Specimens of Iron and Steel for Microscopic Examination," uses only 6 pages to cover this whole subject. In Chap. II, "The Testing of Iron and Steel," the subjects covered include definitions, testing equipment, specimens, various kinds of tests, even fatigue tests, and all of this is done in 14 pages. Similarly "The Manufacture of Steel" is covered in Chap. V in 14 pages, and "Alloy Steels" has been given a like amount of space.

The text is illustrated with 101 figures, many of which are well chosen macrographs and photomicrographs. There are few references in the text, and these are all to books. This publication might be of some use as a first book on the subject and might help the practical worker who has not had technical training, but will be of little use to metallurgists. Oscar E. Harder (0)-B-

PROPERTIES OF METALS (1)

The Elastic Anisotropy of Iron. (Ueber die elastische Anisotropie des Eisen.) E. Goens & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalten,* 1932, No. 12, page 182 (abstract).

Conduction of Electricity and Heat in Crystals of Zinc and Cadmium. (Elektrizitäts- und Wärmeleitung in Zink- und Kadmiumkristallen.) E. Goens & E. Grueneisen. *Annalen der Physik,* Series 5, Vol. 14, July 1932, pages 164-180.

2 Zn and Cd show in the 2 principal directions the accelerated increase of heat conductivity at low temperatures as has been observed in regular metals. The tests are discussed in detail. Ha (1)

Electric Conductivity and Structure of Thin Metal Layers. II. Functional Relations Between Specific Resistance and Thickness of Layer. III. Specific Resistance and Structure as Function of Temperature. IV. A Few Applications. (Zur Elektrizitätsleitung und Struktur dünner Metallschichten. II. Funktionelle Beziehungen zwischen spezifischem Widerstand und Schichtdicke. III. Spezifischer Widerstand und Struktur als Funktion der Temperatur. IV. Einige Anwendungen.) L. Hamburger. *Annalen der Physik,* Series 5, Vol. 10, 1931, pages 789-824, 905-926; Vol. 11, 1931, pages 40-52.

3 Mathematical relations are found for the correlation of electric conductivity of metals in very thin layers and temperature, especially low temperatures, and structure. A few applications of the discussions are made for some structural and chemical conditions of metals. For details the paper must be referred to. 138 references. Ha (1)

The Preparation of Some Rare Metals by Thermal Dissociation. (La Préparation de Quelques Métaux Rares par Dissociation Thermique.) A. E. van Arkel. *Revue Universelle des Mines,* Series 8, Vol. 8, July 15, 1932, pages 37-41.

4 The fact that traces of impurities change the electrical and mechanical properties of metals has caused the author to try to develop methods for the production of absolutely pure metals; he assumes that the easily oxidizable metals Zr, Ti, U, are always covered with thin oxide films which hide the nature of the metals and make them brittle. He succeeded in preparing absolutely pure W, V, B and Ti in a vacuum by a special method and obtained ductile wires. The experiments and some of the properties of the pure materials are described. Ha (1)

Thermal and Electrical Conductivities and Wiedemann-Franz Law of Magnesium and Its Alloys. R. Kikuchi. *Kinzoku no Kenkyu,* Japan, June 1932, pages 239-243.

5 The thermal and electrical conductivities of Mg decrease with the amount of other elements added. The order of the amount of the decrease is as follows: Al, Sn, Zn, Ag, Ni, Cu. The thermal conductivity of Mg containing 12% Al is ¼ as large as that of pure Mg. Both conductivities change with each other, but their ratio is not a constant as shown by the Wiedemann-Franz law. The ratio in the Mg alloys containing Al or Sn is larger than that of pure Mg but smaller in alloys containing Ag, Zn, Cu and Ni. KT (1)

Researches on Beryllium. H. A. Sloman. *Institute of Metals, Advance Copy* No. 616, Sept. 1932, 24 pages.

6 The brittleness of Be was found to be due to a Be-BeO eutectic surrounding the metal grains. The microconstituents of impure Be were identified and their characteristic appearance described. A series of experiments was directed towards the production of Be sufficiently pure to be malleable. Electrolytically deposited Be and cast sections contained too much BeO to be malleable. Thin films of more than 99.9% purity were produced by distillation in a vacuum. Hardness tests indicated that these films were malleable and had a Brinell hardness between 55 and 60. BeO crucibles were the most satisfactory for melting Be, but they, like other materials, introduced O into the melt. A method for plating Be on other metals in a fused electrolyte at 600° C. was developed. Some evidence for allotropic transformation near room temperature was obtained. Extra lines were found in an X-ray diffraction pattern of a sample of Be cast 3 years ago. 7 references. JLG (1)

Condensed from *Engineering Progress,* Oct. 1931. See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 55. MS (1)

Magnesium. (Le Magnesium.) A. Dumas. *Revue de l'Aluminium,* Vol. 8, No. 44, 1931, pages 1477-1484.

9 An account is given of the sources, extraction, methods of manufacture and refining of Mg. See *Metals & Alloys,* Vol. 3, July 1932, page MA 195. Ha (1)

Electrical Properties of Metals in Thin Layers prepared by Thermal and Cathodic Deposition. II. (Proprietes Electriques des Metaux en Couches Minces prepare par Projection Thermique et Cathodique. II.) F. Joliot. *Annales de physique,* Series 10, Vol. 15, 1931, pages 437-454.

10 The analogous electrical properties of thin films prepared by thermal or cathodic deposition indicate similarity in crystalline structure. When the films are heated the resistance increases regularly and reversibly up to a definite temperature range above which there is an irreversible decrease. This property is probably due to recrystallization of the metal. The occlusion of gas in the crystal structure retards the transformation. The resistance of a thin layer is higher than that of the massive metal and increases considerably if the thickness becomes smaller. The thin films absorb gas easily and the occlusion of water vapor increases the resistance. Ha (1)

Electro-chemistry of Iron. (Zur Elektrochemie des Eisens.) S. Bodforss. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 160, June 1932, pages 141-157.

An electrode of carbonyl Fe incorporated in a specially designed testing apparatus, is constantly ground off in various solutions and the potentials are determined. The measurements proved that the potential of Fe in aqueous solutions and at ordinary temperatures is a straight line function of the hydrogen ion concentration and of the anions. No evidence was found that ferro or other metal ions exert any influence within the limits of error of the method applied. The author doubts that the normal potential of Fe has actually been determined by e.m.f. measurements with Fe electrodes in Fe salt solutions. The concentration of potential-determining ions present must be taken into account in order to express the normal potential of the reaction taking place in the cell. The dependence of the potential on the concentration of the corresponding metal ions, as claimed by the Nernst formula, does not hold true for ordinary ions with reference to the testing conditions. The reaction $Fe \rightarrow Fe^{\cdot\cdot} + 2\,\theta$ probably occurs at room temperature so slowly that it is superimposed by other processes which proceed faster and thus determine the potential. The investigator sets out to interpret the effect of the H-ions on the basis of Fe-H alloy formation, but his hypothesis does not explain the action of the anions. Next an attempt is made to cover the phenomena observed by assuming an oxide formation and the special properties of the oxide layer are described which are required to satisfactorily explain the experimental observations. Probably we are dealing with adsorption potentials and the potential of Fe and other inactive metals should have the same genesis as the potentials of glass, graphite, quartz and paraffine electrodes. 20 references. EF (1)

Corona Losses on Copper and Aluminum Cables. (Koronaverluste and Kupfer- und Aluminiumseilen.) K. Potthoff. *Elektrizitätswirtschaft,* Vol. 30, Sept. 1931, pages 526-530.

Experiments were performed on Cu and Al cables of 70, 95 and 120 mm.² cross-section with the object of determining the corona losses in dependence on the state of surface and the changes of the corona losses due to corrosion and atmospheric conditions. The testing method is discussed in detail and the results are graphically presented. These may be summarized as follows: The largest corona losses are noticed on new Cu ropes, the lowest on old Al-ropes. At low loads (5 kw./km. max) the effect of the metal surface condition superimposes the influence of the diameter; old Cu rope (uniformly oxidized and no injuries detectable at the surface) is about equivalent to new Al-rope. The surface defects on Cu ropes are less harmful the larger the diameter. Generally speaking the following order of merit in regard to corona losses was established: Cu new, Cu old, Al new, Al old, the latter showing the lowest corona losses. EF (1)

The Changeability of Damping of a Material. (Die Veränderlichkeit der Werkstoffdämpfung.) P. Ludwik & R. Scheu. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, July 9, 1932, pages 683-685.

The damping capacity of a material is called that energy which is converted into heat when the material is subjected to alternating stresses, and is referred to one complete cycle and the unit of volume or weight of the subjected sample. It is measured by the hysteresis energy as taken by the optical hysteresis loop in a torsion-vibrating machine; the loop is plotted as hysteresis energy in kg.cm./cm.³ against the number of cycles as abscissae. The results with several materials are reproduced and discussed, the damping is greatly dependent on frequency and temperature. Phenomena of strengthening and weakening of the material are considered responsible for the hysteresis. Ha (1)

The Transformation of White into Gray Tin (Tin-pest). [Die Umwandlung des weissen in graues Zinn (Zinnpest).] G. Tammann. *Zeitschrift für Metallkunde,* Vol. 24, July 1932, pages 154-156.

Review of the physico-chemical bases for tin-pest, with a discussion of the linear transformation velocity of white into gray tin as affected by temperature, and crystal orientation of the white tin, and also of the effect of additions of Pb, Cd, Bi and Sb in decreasing this velocity, taken from the work of Tammann and Dreyer (*Zeitschrift für anorganische Chemie,* Vol. 199, 1932, page 97). RFM (1)

Production and Properties of Pure Platinum. (Herstellung und Eigenschaften reinen Platins.) Thews. *Die Metallbörse,* Vol. 22, Jan. 30, 1932, page 130.

While the original Wollastone refining process is still in use, the introduction of the high-frequency furnace was of particular significance for the melting technique of Pt and its alloys. The hammer-welding of Pt, the influence of impurities, the physical and chemical properties of the pure metal are fully dealt with. Special attention is paid to the absorption of gases, particularly of hydrogen. EF (1)

Sodium and Potassium Metals. Paul M. Tyler. *Information Circular* 6579, United States Bureau of Mines, April 1932, 7 pages.
General. AHE (1)

Textbook of Physical Metallurgy. (Lehrbuch der Metallkunde.) Gustav Tammann. 4th Edition. Leopold Voss Verlag, Leipzig, 1932. Paper, 6 x 9¼ inches, 536 pages. Price 49.50 RM.

The 3rd edition of this treatise appeared in 1923 and was translated into English by Dean and Swenson. Many of the sections of the 3rd edition have been greatly extended or rewritten. The book shows evidence of quite recent revision as many data published this year are included.

The first part of the book discusses the properties of metals, and gives many interesting facts difficult to uncover from other sources. The section dealing with work-hardening and softening of metals is extensive and highly interesting. The second half of the book deals with binary and ternary alloys; types of equilibrium diagrams and actual diagrams are discussed. A valuable part of the book is the special index, which lists references to the most important investigations of several hundred alloy systems. The book is adequately indexed.

No serious student of physical metallurgy can afford to ignore this work. J. L. Gregg (1)-B-

PROPERTIES OF NON-FERROUS ALLOYS (2)

The Heat-Treatment and Annealing of Aluminum and Its Alloys. N. F. Budgen. Chapman & Hall, Ltd., London, 1932. Cloth, 6½ x 10 inches, 341 pages. Price 25s.

During the quarter of a century since Alfred Wilm took out a patent on an alloy, which might be called the first duralumin, to the present time (1907 to 1932) an enormous amount of research work has been done, and numerous articles have been published regarding the composition, heat treatment, and properties of aluminum alloys. The present treatise by Budgen, with a foreword by Prof. D. Hanson of the University of Birmingham, brings together in a single volume and in a well arranged form this extensive information. The method of presentation is a happy balance between the viewpoint of the physical metallurgist and the industrialist.

The general scope of the treatise is indicated as follows: Part I, Heat-Treatment of Wrought Pure Aluminum; Part II, Heat-Treatment of Cast Pure Aluminum; Part III, Heat-Treatment of Wrought Aluminum Alloys; Part IV, Heat-Treatment of Cast Aluminum Alloys; with appendices on the following subjects: I, Practical Details of Melting and Alloying Procedure in the Preparation of Hardener Alloys; II, The Influence of Heat-Treatment upon Corrosion Embrittlement; III, Mechanical Properties of Aluminum and Various Aluminum Alloys at Elevated Temperatures; IV, Pinholes in Aluminum Castings and Their Effect on Heat-Treatment; V, Standard Colour Scheme for Marking Aluminum and Its Alloys; VI, Aluminum Bronze and Its Heat-Treatment; VII, Bibliography of the Heat-Treatment of Aluminum and Its Alloys; and VIII, Bibliography of Aluminum Bronze.

The author has collected his information from a wide source of literature, acknowledgment being made to some 38 principal contributors to the information, and has in addition included a very large amount of original information, which has apparently not been published previously. The 231 figures represent a well chosen collection of microstructures, macrostructures, equilibrium diagrams, property curves, and photographs of industrial products and installations.

The author has indicated in the preface that the book is offered to manufacturers and industrialists, to the academician, and to the general reader. The general treatment of the various subjects is such that the text should be followed by those not specially trained in physical metallurgy, while at the same time the latest developments in this field have been included, and the author has done well in presenting complicated and involved theories.

The numerous aluminum alloys which have been developed for use in the wrought and in the cast condition are discussed in great detail, and reference in all cases has been made to the commercial or trade name under which these alloys are produced.

Throughout the text there is extensive reference to the original literature, and Appendices VII and VIII have 20 pages of bibliography.

The American reader will object to the fact that the author has expressed the tensile strength in tons/in.^{2} and will be amused that in the early part of the text the author has used "shew" and "shewn," while in the latter part he has used "show" and "shown." He will be disappointed that the author has given the entire credit for the invention of the manufacture of aluminum by electrolysis to Héroult and has not mentioned Hall, who was undoubtedly an independent American discoverer, and he may feel that not enough credit has been given to the researches by Merica, Waltenberg, and Scott, published in 1919 relating to the age hardening of the duralumin types of alloys at the time when Dr. Rosenhain in his "Introduction to Physical Metallurgy" wrote " . . . this remarkable behaviour (age-hardening) constitutes one of the most striking unsolved problems in present-day physical Metallurgy." (The quotation is from Budgen's Introduction.)

The book is well written, is a valuable collection of information, and should have a good reception by the three classes of readers for which it is intended by the author.

Who is not interested in the historical development, chemical composition, methods of alloying, melting and casting practice, properties as cast and as heat treated, heat treating practices and theories, macro- and microstructures, and principal uses of pure aluminum and especially such alloys as Duralumin, Superduralumin, Aldrey, Almelec, Silmalec, 51S, Anticorodal, Aludur, Almalsilium, Montegal, Hyblum, Lautal, Aeron, 25S, L. M., Aldal, 17S, Almag, Alferium, "Y" Alloy, Aeral, Arional, RR50, RR53, RR56, RR59, Alclad, Duralumin Substitute, LIV, Wilmil, Alpax, Allautal, Constructal, Skleron, "E" Alloy, Magnalite, Alneon, Neonalium, Aluminum-Beryllium Alloys, Aluminum Bronze, etc., etc.?

Oscar E. Harder (2) -B-

Magnetic Properties of Copper-Nickel Alloys. E. H. Williams. *Physical Review*, Vol. 37, June 1931, page 1681.

The magnetic susceptibility of alloys of Cu and Ni in proportions ranging from 0.1-70% Ni have been studied. Although Cu is only weakly diamagnetic, it requires 0.8 or 0.9% Ni to neutralize this diamagnetic effect, and 56% of Ni is required before the alloy shows ferro-magnetic properties at ordinary temperatures. For amounts of Ni from 1 up to 30% the alloy, whilst paramagnetic in most respects does not obey any law of paramagnetism with regard to temperature. As the temperature is increased the susceptibility first increases and then decreases, the maximum occurring in the neighborhood of the Curie point for Ni. In the case of alloys containing more than 30% of Ni, the susceptibility decreases with increasing temperature for temperatures above 20° C. So far as the phenomena of increasing paramagnetic susceptibility are concerned, there is at present no explanation. It has been suggested that a few atoms or molecules of Ni do not lose their magnetic identity in the alloy, and that these atoms, with their spinning electrons, become more mobile as the temperature is increased. One objection to this is that the susceptibility is independent of the field. WAT (2)

Special Aluminum Alloys. (Spezialaluminium-legierungen.) E. R. Thews. *Die Metallbörse*, Vol. 22, Apr. 30, 1932, pages 545-546; May 7, 1932, pages 577-578.

The writer alphabetically compiles the chemical analyses of Al alloys known under the following trade names: "A" Aluminum, Acibal, Aeral, Aero Metal, Aerolit, Aeronin, Aldal, Aldrey, Alferium, Almasilium, Aludur, Alneon, Alpax, Aludur 533 + 570, Alumac, Alunean, Aluminit, Alunit, Alusil, Alzen-Metal, Alzin Metal, American alloy, Anticorodal, Argibit, Aviatik Benz, Avional, Bell Metal, Bersch bearing, Birmabright, Bohnalit, Bourbonnes, Constructal 2 + 8, Deutsche alloy, Drittelsilber, Duralum, Duralumin, Durandmetall, Duranic "E" + "F" Alloy, Fletcher metal and bearing, Fontane Metal, Fiary Metal, "G" Metal, Grossman, Haasmetall, Halumin, Hartaluminium, Helumin, Hiduminium, Huron metal, Hyblum, Hyman Inalium, "K" Alloy, KS Seewasser und Kolben, Koltchougalumin. "L-5," Lautal, Liberty Kolben, Lohmanit, Lynit, Maradamit, Mach's alloy, Magnalit, Magnalium "X," "Y," "Z," Maluminium, Manchardt's metal, Meterorit, Mocksilber, Murman's Metal, Navy Aluminum, Nelson Bohnalit, Neonalium, Nickeloy, Nürnberger Gold, Page Dentalmetall, Partinium, "RR" Hiduminium, Rohmium, Romanium, Rübel metal, Ruselit, Scleron, Sibley, Silumin, Suprakolbenmetall, Susini, "T" metal, Telectal, Thalassal, Tiers Argent, Verelit, Vital, Willmill, Woltramium, "Y" alloy, Zimalium, Zisium, Siskon. The analyses of different brands, commercially distributed under the same trade name, are given for some of the alloys listed above. In addition to this, the trade names of further Al alloys are stated, but no analyses are given. In some cases the alloying elements are given. 45 references. EF (2)

Alloys of Gallium. (Legierungen des Galliums.) W. Kroll. *Metallwirtschaft*, Vol. 11, Aug. 5, 1932, pages 435-437.

Alloys of Ga with Fe, Ni, Cu, Zn, Mg, Bi, Al, Pb, Cd and Sn were examined for hardness and other mechanical properties. Ga has little effect on Fe, Ni and Cu, while it makes Zn brittle. The lowest melting point alloy obtained was with 12% Sn, which melts at 15° C. This alloy might be used for filling thermometers. Gas has little effect on Al in the binary alloy, but in the ternary alloy with Al and small quantities of Mg it acts similarly to Zn. With 4% Ga a Brinell hardness of 119 was obtained after quenching from 520° C. and aging at 130° C. However, these alloys have poor corrosion resistance. There is not likely to be any practical use for Ga alloys. 4 references. CEM (2)

Dynamic Strength Properties of Several Light Metals. (Dynamische Festigkeitseigenschaften einiger Leichtmetalle.) K. Matthaes. *Zeitschrift für Metallkunde*, Vol. 24, Aug. 1932, pages 176-180.

The following alloys were studied: Duralumin, Lautal, Aeron, Elektron "Deutsche Legierung" (Al with 0.23% Si, 1.50% Cu, 0.60% Fe, 15.31% Zn, 0.12% Mg). Stress-strain curves (for bending and torsional stresses) are given for the alloys named; also notch-impact curves in the temperature range −180° to +100° C. The notch-impact values for Al-alloys increase with diminishing temperature, but for Mg-alloys decrease. Curves are given showing the effect of changing cross-section upon the endurance (for bending stresses) of Elektron. Anodic oxidation of duralumin is shown to increase its resistance to corrosion-fatigue. (2)

A Study of Certain Light Aluminum Alloys and Aluminum Bronzes. (Etude de Certains Alliages legers d'Aluminium et de Bronzes d'Aluminium.) Camille Matignon. *Chimie et Industrie*, Vol. 27, June 1932, pages 1259-1273; Vol. 28, July 1932, pages 23-36.

The conclusions reached in the first part of the study are as follows: (1) All the light alloys deteriorate more quickly than Ag. (2) Al bronze with 9% Al is much more resistant to deterioration than a monetary bronze; even with 7% Al, there is a tendency towards less resistance. (3) Tests made by Messieurs Schloesing and Badin conform to the extent that the alloys can be classed according to their corrosion resistance in the following order: bronze with 9% Al; bronze with 7% Al and monetary bronze; Ag; alloy R-4, Kallium 250, Kallium 350; alloy A-5 with 10% Al-Mn, 10% Al-Zn, 10% Al-Ag; Kallium 100; Beka; alloy with 5% Al-Mn. From the results of the tests on the first and second groups, it can be seen by comparison that alloy R-4 takes its place beside Kallium 250 and 300 and alloy A-5 beside the alloys with Mn and those with 10% Ag. From chemical tests it follows that: (1) the alloys with 5 and 10% Mn have a greater resistance to sea water; (2) the alloys most severely attacked are the 5 and 10% Al-Ag alloys; the results confirm those already obtained with the alloy A-5 of Boute, which contains 5% Ag; (3) the alloy with 10% Zn is less resistant than the alloys with Mn; it is more readily attacked than R-4, as shown by examination and indicated in tables; (4) the Kallium alloys appear a bit inferior to alloy R-4. Their inferiority is particularly apparent when parts are left in the solution, for they continue to oxidize; (5) bronze with 7% Al is still attacked by NaCl solutions; on the other hand, it resists Na solutions well, even caustic soda solutions. Part II. The author describes his experiments and comes to the following conclusions: The Al bronze of Sainte-Claire Deville appears to possess all the properties of an excellent monetary metal: (1) Its preparation requires care but does not present real difficulties. The use of sufficiently pure materials and protection from oxidation during melting and cooling simplifies this operation. (2) The industry thus can be furnished with a homogeneous product of sufficiently constant composition. (3) The Al bronze prepared with the usual technique is not difficult to work. Moreover it does not oxidize appreciably during that process. (4) Its mechanical properties are similar to those of acid Bessemer steel with 0.35% C. It has a high resistance to torsion. (5) Its properties after annealing and tempering vary within wide limits, particularly its elastic limit and its tensile strength. This property can be used profitably. (6) It is inexpensive and readily available. (7) It has an attractive color and takes a polish perfectly. (8) Al bronze does not have the unpleasant odor of Cu. (9) Though it is not as light as Al and other alloys studied, its density is about 15% less than that of monetary bronze and its mechanical properties are remarkable. MAB (2)

PROPERTIES OF FERROUS ALLOYS (3)

The Ferromagnetic Alloys and their Industrial Application. (Die Ferromagnetische Legierungen und ihre gewerbliche Verwendung.) W. S. Messkin & A. Kussmann. Julius Springer, Berlin, 1932. Cloth, 6¼x9¼ inches, 418 pages. Price 44.50 RM.

1 Of the authors, Messkin is chief of the section on magnetic alloys in the Institute of Metallurgical Research in Leningrad and Kussmann is a member of the magnetic laboratory of the Physical Technical Institute in Berlin—Charlottenburg. Collaboration may be said to be the keynote of this monograph. No other work combines so successfully the thorough and yet not difficult treatments of the science and practice of magnetics, of the physical metallurgy of magnetic alloys, and of the considerations governing the practical utilization of these alloys contained in this book. The preface states that the original manuscript by Messkin was revised and extended by Kussmann. It is not plain whether or not the original was in Russian. At any rate the final German text makes unusually clear and easy reading.

2 There is a good elementary exposition of magnetic properties and magnetic testing followed by a very complete general discussion of the relations between the constitution and structure of the various magnetic alloys and their magnetic properties. Here the iron-carbon alloys provide the main illustrative subject matter, but the other alloys are not slighted and adequate discussions with constitution diagrams are given of the Fe-Co, Fe-Cr, Fe-Ni, Fe-Si, Fe-W, Ni-Co, and other alloys. The effects of heat treatment and also of deformation are excellently covered. There is a fairly good chapter on magnetic analysis. The chapter on machinability and hot and cold workability of magnetic alloys while good seems rather brief in comparison with the proportions of the other parts of the book. This much covers about half of the text. The rest, devoted to a detailed discussion of the properties, treatment and applications of specific magnetic materials, probably constitutes the most valuable part of the book. This portion is divided into three sections—on permanent magnet steels, on dynamo and transformer materials, and on magnetic alloys for special purposes. Good accounts are given of the cobalt magnet steels and of the permalloys.

3 At every turn the treatment is skillful, well informed and astonishingly up-to-date. There is some apparent overlapping between the first and second parts of the book but, of course, no actual duplication. There is a good index. Due to the wide scope, some of the material is condensed as in a handbook, but for the most part the style is interpretative and critical and in the best encyclopedic tradition.

Samuel Epstein (3) -B-

High-Test Iron for Pressure Castings. H. H. Judson. *Transactions American Foundrymen's Association,* Vol. 3, July-Aug. 1932, pages 153-167.

4 To make satisfactory cast Fe for pressure castings the metal is taken from 2 cupolas. One cupola operates on charge of steel scrap, Si pig and spiegeleisen producing an iron with 2.40-2.80% C and 1.40-1.80% Si. The second cupola produces an iron with 3.50% C and 2.40% Si. In mixing the ratio of low C to high C iron is 3.5 to 1 giving a product with 2.74% total C, 0.75% combined C, 1.70% Si and 1.09% Mn. The properties of the latter are 46,500 lbs./in.² tensile and 51,500 lbs./in.² shear strength, 212 Brinell hardness and 6,000 lbs./in.² bursting pressure. Transverse tests of 1¼" round arbitration bars on 12" centers gave 5,000 lb. strength and 0.09" deflection. It is remarkable that in casting this metal no risers are used regardless of casting section.

OWE (3)

The Structure and Mechanical Properties of Cast Iron. J. G. Pearce. *International Association for Testing Materials, Zurich Meeting, 1931,* Vol. 1, 1932, pages 6-14.

6 The properties of cast Fe vary not only with composition but also with melting conditions which affect the size and distribution of the graphite. If all graphite is in solution and no nuclei are added, a soft, machinable iron with fine graphite will result, while if nuclei are present, the same iron will be pearlitic. A mixed structure, which may also be obtained, is inferior to either. The structure depends on the nuclei and these depend so much on melting conditions that change of strength can only be correlated with change in Si for given melting conditions. This is illustrated by curves for different Si and different size bars for compositions and melting conditions leading to variation in type of graphite. 3 references.

HWG (3)

Hardness and Machinability of Cast Irons. (Dureté et Usinabilité des Fontes.) C. Baron. *La Fonderie Belge,* Vol. 2, Apr. 1932, page 66.

7 Comparative results (concerning pearlitic, ferritic and austenitic cast irons) given for hardness and machinability show that hardness number without indication of structure gives no measure of machinability. When structure is indicated, hardness number gives valuable information on machinability. However the author has found cast irons with normal hardness and low machinability, this fact being probably due to numerous Mn sulphide inclusions which do not affect hardness but disturb the cutting action of tools.

FR (3)

The Strength of Materials as Affected by Discontinuities and Surface Conditions. F. C. Lea. *Engineering,* Vol. 134, Aug. 26, 1932, pages 256-258; Sept. 2, 1932, pages 280-281.

8 Condensed from paper read before a joint meeting of the Ceramic Society and the Society of Glass Technology, Feb. 24, 1932. Gives results of tests on C steels containing from 0.09 to 0.86% C and on Ni-Cr steels. Discusses plasticity and discontinuities, effect of surface conditions produced by heat treatment of steels, effect of cold working on surface conditions, effect of corrosion on failure under repeated stresses, and static and dynamic impact tests.

LFM (3)

Effect of Section On Tensile Strength of Gray Iron. F. P. Gilligan & James J. Curran. *Iron Age,* Vol. 129, May 1932, pages 1106-1107, 1125.

9 Gives results of investigation of the sections of some large gray Fe cylinders which failed in service. References in the literature are very meager on the strength of cast Fe in heavy sections. Refers to the work of Rather and Bolton on the subject. The castings investigated were hydraulic cylinders, weighing about 30,000 lb. each, with wall thickness of about 10½". Internal pressure to which they were subjected reached as high as 6000 lb./in.² The composition of the 2 cylinders were:

	Total C	Mn	Si	P	S
No. 1	3.48	0.49	2.18	0.588	0.072
No. 2	3.48	0.71	2.26	0.682	0.055

Authors conclude that strength of castings of different thickness follows a definite law and the effect of composition is greatly minimized as the section increases. Give the probable strength range for all composition in heavy sections and a chart for sections from 2" to 10½" thickness.

VSP (3)

Is Carbon Steel used to the Best Advantage? Bernard Thomas. *Iron & Steel Industry & British Foundryman,* Vol. 5, Apr. 1932, pages 273-275.

10 Carbon steels, in many instances, may be used instead of alloy steels, providing always that conditions are carefully considered beforehand and wherever possible correct heat treatment is applied. A number of examples are cited where the higher costs of alloy steel are paid in cases where a straight carbon steel would suffice if only care and attention was paid to manufacturing and heat treating details.

The Aging of Mild Steels after Hardening and its Consequences for Fusion Welding. (Das Altern der weichen Stähle nach dem Härten und seine Folgerungen für die autogene Schweissung.) Seigle. *Die Schmelzschweissung,* Vol. 11, Aug. 1932, page 173; *Revue de la Soudure Autogene,* 1932, No. 219, pages 2514-2516.

12 Tests on steels hardened in water from 500° to 950° C. showed that a soft Thomas steel, after hardening at 625° C. had a tensile strength of about 40 kg./mm.², a month later more than 60 kg./mm.² When hardened at 700° C., the figures were 50 and 70 kg./mm.² respectively and at 800° and 900° C., 50 and 60 kg./mm.² Equilibrium was obtained at 600°, 800° and 900° C. after 20 to 25 days, at 700° C. after 30-35 days. The notch-toughness shows, however, a decrease in value with time. Welded pieces should not be cooled in red-hot state, the welder must wait and immerse the piece in water only after it is reasonably cool. The question of corrosion and failures is discussed in the light of results from these tests.

Ha (3

Physical Properties of Heat-treated Cast Iron. F. G. Sefing & M. F. Surls. *Michigan State College Engineering Experiment Station Bulletin* No. 47, June 1932, 36 pages.

13 Detailed data are given on tensile, transverse and impact tests of irons with 3.20-3.56% total C, 2.51-2.75% Si, having 7% steel in the cupola charge and of those with 3.22-3.38% total C, 2.36-2.57% Si, having 25% steel in the charge; in annealed, water-quenched and quenched and tempered conditions. The authors say: "It is regretted that tapping and pouring temperatures of the irons are not available for it is believed that they have a profound influence on the properties of the iron. There is little explanation or theory advanced concerning the structural changes that take place. Reasons for the results are omitted so that the data shall stand on their own merits." The trends of the data are in general along the lines that would be expected, but the individual data are erratic, and it is difficult to draw definite conclusions from the graphs. The materials classed together varied somewhat as to structure and properties in the as cast condition and these initial differences are thought to affect the properties after heat-treatment.

HWG (3)

The Heat Treatment of Chromium-Magnetic Steel. (Die Wärmebehandlung von Chrom-Magnetstahl.) Wenjamin S. Messkin & Emeljan S. Towpenjez. *Archiv für das Eisenhüttenwesen,* Vol. 6, Aug. 1932, pages 75-78.

14 Report of the Institute of Metallurgy Research in Leningrad. The purpose of this paper was to study the magnetic properties of an open-hearth steel, containing 1.33% C, 0.37% Si, 0.55% Mn, 0.048% P, 0.033% S, 2.15% Cr and 0.065% Ni, under various heat treatments. It was established that the best magnetic properties were obtained by hardening at 850° C. in oil. The steel should not be held too long at temperatures between 750° and 850° C., because the magnetic characteristics would be impaired. It is probable that certain reactions taking place in the Cr bicarbides are answerable for this harmful effect on magnetic properties of the steel. In order to improve a steel impaired by wrong heat treatment, it should be heated up to between 950° and 1000° C., kept at this temperature from 30 min. to 1 hr., and then quenched in the atmosphere. The customary hardening will then follow. In the above case if the steel was overheated during normalizing, then it should be annealed at 150° to 250° C. prior to hardening. Results and conclusions made in past work on this subject have been confirmed in general. For example, it was shown that no unlimited relation exists between coercive force and hardness. Likewise during tempering of hardened steel it is indicated that the measurement of the magnetic saturation may be replaced by the measurement of the maximum induction.

DTR (3)

Refined Steels. (Vergütungsstähle.) E. Eichwald. *Automobilischnische Zeitschrift*, Vol. 35, Aug. 10, 1932, pages 363-369.

The article contains a comprehensive review of 11 standardized and 155 other steels and alloyed steels as they are now made in Germany. The list gives manufacturer, composition, tensile strength, elastic limit, elongation, reduction of area, heat treatment for forging, annealing, hardening and tempering, and the principal fields for application. A special list shows the best steels for automobile parts. Unalloyed steels are generally used for parts with low endurance stresses. A refined steel is defined as a steel of special composition, the mechanical properties of which can be improved after forging by a certain heat treatment; they are particularly resistant to endurance and alternating stresses and to wear. Ha (3)

High Strength Cast Iron with Pearlitic Structure (Fonte de Haute Qualité à Texture Perlitique). E. Brialmont. *La Fonderie Belge*, Vol. 2, Mar. 1932, pages 45-47.

Cylinders for steam and Diesel engines as well as pistons and piston rings must be hard enough to resist wear. There is a close relation between hardness and strength. On previous castings, thicknesses must not be too heavy to prevent low hardness and strength. In Belgium, specifications are as follows: (1) Shock resistance: at least a drop of 45 cm. of a 12 kg. mass on a test-bar with square section 40 x 40 mm. and 160 mm. between supports. 1st drop = 35 cm., 2nd drop = 40 cm., 3rd = 45 cm., etc. . . . (2) Brinell hardness: at least 207. Advantages of high quality cast Fe are: (1) castings have a high surface finish after machining; (2) fine graphite reduces abrasive action on wearing parts; (3) high resistance to wear; cylinders remain true cylinders; (4) absence of leakage in joints of wearing parts and corresponding high efficiency of gas pressure; (5) long life of machines. Test results are given for 30 different cast irons. Drop height varies between 50 and 70 cm., tensile strength between 26.7 and 29.9 kg./mm.^{2}, Brinell hardness between 208 and 235. FR (3)

Effects of Inclusion Streaks on the Tensile and Dynamic Properties of Wrought Iron and Similar Materials. F. R. Hensel & T. F. Hengstenberg. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 488, Oct. 1932, 29 pages.

Tensile, Brinell, impact, and endurance tests were made on hand-puddled wrought Fe, artificial wrought Fe, ductile and brittle ingot Fe, and medium C steel with and without ghost lines. Both longitudinal and transverse samples of hand-puddled wrought Fe and mild steel were used. The tests indicated that inclusion stringers do not influence the mechanical properties when the stress is parallel to the stringers. Both wrought Fe and ghost-line steel gave lower values of strength, elongation, impact resistance, and endurance limit when the stress was perpendicular to the stringers. The tensile values for tests on wrought Fe parallel and perpendicular to the stringers were 46,300 and 35,600 lbs./in.^{2} tensile strength, 24,900 and 22,500 lbs./in.^{2} yield point, 29.6 and 6.6% elongation in 2", and 35.7 and 6.7% reduction of area. The Izod impact values were 35.5 and 10.0 ft.-lb. The endurance limits were 27,300 and 22,200 lbs./in.^{2}, respectively, for stresses parallel and perpendicular to the stringers. Tests were made on a Farmer-type machine. The brittle ingot Fe had low impact values. Tests over a range of temperatures indicated that the almost vertical part of the impact-temperature curve was shifted to higher temperatures for the brittle Fe. Tests on carburized samples showed that the effects of inclusions are much more pronounced in a relatively hard matrix than in the soft Fe matrix of wrought Fe. This paper was prepared for presentation at the Buffalo meeting, but was withdrawn after it had been issued as a Technical Publication. 37 references. JLG (3)

The Influence of the Carbon Content on the Structure and the Tensile Properties of Gray Iron with Consideration of different Silicon Contents, Pouring Temperatures and Wall Thicknesses. (Einfluss des Kohlenstoffgehaltes auf das Gefüge und die Festigkeitseigenschaften des grauen Gusseisens, unter Berücksichtigung verschiedener Siliziumgehalte, Giesstemperaturen und Wandstärken.) A. Koch. Doctor's thesis, Technische Hochschule, Aachen, June 1932, 15 pages.

Systematic tests under uniform conditions are described, the results of which can be stated briefly as follows: The content of graphite of cast Fe increases with increasing C content; the structure is thereby weakened which causes a deterioration of all tensile properties. For the same pouring temperature the "effective" overheating is reduced with decreasing C content which causes a finer structure and improves especially the endurance impact strength. Si improves the pourability but lowers the mechanical properties by greater segregation of graphite and disintegration of carbide. An increased cooling velocity (small wall thickness, low pouring temperature) counterbalances this injurious influence of Si to a certain extent; for each C content and for each wall thickness and pouring temperature there exists an optimum of Si content. Increasing wall thickness increases the graphite content, bending and tensile strength decrease, the hardness is greatly influenced. Increasing pouring temperature increases the preheating of the mold, solidification is delayed, segregation of graphite favored; the latter again lowers the mechanical properties. In order to obtain high values of strength the pouring temperature should be as low as possible; the lowest temperature is given by the liquidus point for the respective composition of the Fe. The test results are reproduced in full. 27 references. Ha (3)

Growing of Cast Iron. (Das Wachsen von Gusseisen.) Otto Edling. *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Sept. 4, 1932, page 462.

The various causes of growing are discussed: (1) progressing decomposition of free Fe_3C and pearlitic Fe_3C or the separation of C from the solid solution at temperatures above 710° C., (2) disintegration of structure due to temporarily shifted effects of structural transformations and stresses thus originating, (3) type of graphite formation, (4) oxidation, (5) gas content, (6) supposed effects on disintegration due to vibrations and (7) oxidation of the Si in ferrite to SiO_2 or silicates. GN (3)

Variation in Hardness as a Function of Thickness in Cast Iron Castings. (La Variation de la Dureté en Fonction de l'Epaisseur dans les Moulages de Fonte.) M. Ballay. *La Fonte*, Oct. 1931, pages 51-56.

Ordinary cast Fe tends to be white or mottled in light sections and gray in heavy sections of castings. When Fe is gray throughout the casting, graphite is fine in light sections and in coarse flakes in heavy sections. Then there is a variation of hardness between different thicknesses in the same casting; this is called "heterogeneity of section." But in the same section of a casting hardness varies also from skin towards inside; this is called "heterogeneity in depth." For lessening heterogeneity in ordinary cast irons C content must be as low as possible but high enough to have light sections of castings with gray structure. It is also possible to decrease the difference between cooling rates of sections by heating the mold. Cr, Mo, V, increase heterogeneity in alloy cast irons. Ni, when substituted for a part of the Si of the Fe is a valuable element to lessen heterogeneity. When Si content cannot be lowered, Ni and Cr additions are made together in the ratio Cr/Ni = ⅓-¼. In martensitic irons, heterogeneity is light and can be lessened by suitable annealing treatment. Austenitic cast irons are very homogeneous. Heat treatments are mentioned. FR (3)

Stability and Retention of Temper of Steels Containing Certain Difficultly Soluble Carbides. (Haltbarkeit und Auslassbeständigkeit von Stählen mit Schwerlöslichen Sonderkarbiden.) Eduard Houdremont, Hubert Bennek & Hans Schrader. *Archiv für das Eisenhüttenwesen*, Vol. 6, July 1932, pages 24-34.

Report 182 of Committee on Materials of Verein deutscher Eisenhüttenleute. Includes discussion. The manner in which certain carbides affect hardness and temper was studied for W steels and particularly for V steels. As a result of the removal of C for the formation of the carbides in question, the hardness of these steels is diminished when compared with C steels at equal hardening temperatures, because most of these special carbides are much less soluble than cementite. On account of the action of these carbides in arresting crystallization, these steels are only slightly sensitive to overheating. With rising temperature the carbides continue to go into solution more and more, the critical rate of cooling decreases, and hardening increases throughout the material. During annealing, these special carbides, that are difficultly soluble at elevated temperatures, separate or precipitate out. This precipitation occurs first at high temperatures and again from the α-solid solution, producing thereby a kind of precipitation hardening. This in turn compensates for a falling off in hardness due to the disintegration of martensite and leads to the secondary rise in hardness between 500° and 600° C. This precipitation of V carbide is the cause of the higher cutting performance and strength under heat of V steels, that are given appropriate preliminary treatment. With highly alloyed steel, for example high speed steels, an additional rise in hardness may be had through transformation of the residual austenite. The retention of temper, in comparison, is solely dependent on true precipitation hardening of the carbides in question. The action of V was examined still further on many alloyed construction steels. After corresponding heat treatment the effect is likewise manifested in a high retention of temper. Simultaneously however, the notch strength or toughness dropped off proportionately as a result of the separation of V carbide. Tables of results and graphs are given showing effects of varying additions of W or V, annealing temperature and time, cross-section of bar, etc., on hardness, retention of temper, heat strength, cutting performance, and other physical and magnetic properties. DTR (3)

New Developments in Alloy Steels and Irons. *Canadian Chemistry & Metallurgy*, Vol. 16, Sept. 1932, pages 240-242.

A series of 18-8 Cr-Mn steels containing 17-19% Cr, 5-10% Mn, and small % of Cu or Cu and Ni have been developed recently. Varying the amounts of alloying elements makes it possible to produce a grade suitable for the production of castings or one adapted to the manufacture of wrought articles. Strength is maintained to a remarkable degree at temperatures from 1375°-1650° F. For moderate corrosion and heat resistant use a 4-6% Cr alloy steel has been introduced. A Ni-Mn-Fe alloy resists HCl to a high degree, also H_2SO_4, acetic acid, and formic acid. It may be cast, forged, or rolled, and welded by oxyacetylene or the electric arc. Cromansil steels contain relatively small amounts of Cr, Mn and Si and are used as new engineering steels. They are produced by the open hearth process. WHB (3)

Molybdenum-Copper Steel (Molybdän-Kupferstahl [Witterungsbeständiger Stahl]). Wiessner. *Bautechnik*, Vol. 19, Aug. 26, 1932, page 472.

The weather stability of Cu steels can be increased further by adding Mo. Typical analysis: 0.8-1.4% Mn, 0.4-0.7% Si, 0.25-0.6% Cu, up to 0.3% Mo, 0.20% C is best for parts up to 18 mm. thick and 0.25% for parts above 18 mm. Good welds are obtained with all types of welding methods. Electrically butt welded seams give a tensile strength of at least 90% of the base metal. The steel is particularly adaptable to riveting. Conditions when this steel is economically to be used as structural steel are discussed. The principal field of application is bridge building, exhibition and industrial halls with a large span width. GN (3)

Refractory Cast Iron and its Production. (Les Fontes Rèfractaires et leur Fabrication.) G. D'Ardigny. *Revue de Fonderie Moderne*, Vol. 26, Aug. 25, 1932, pages 265-270.

The expansion curves of a cast Fe at heating and cooling and the way they are affected by graphitization, transformations of the Fe phases and by internal stresses are discussed and explained by examples. To obtain a cast Fe as free as possible of irregular expansion and behaving well under heat, the content of Si and C should be small and that of Mn great; the addition of Cr, Ni-Cr, Ni-Cu-Cr is advantageous. The relative importance of these factors is determined by the ultimate use of the metal; they must be selected according to the machinability, castability and means of melting available. Several compositions for various purposes are given. Ha (3)

Contribution to the Mechanics of the Plastic Behavior of Mild Steel. (Beitrag zur Mechanik des bildsamen Verhaltens von Flusstahl.) K. Hohenemser & W. Prager. *Zeitschrift für angewandte Mathematik und Mechanik*, Vol. 12, Feb. 1932, pages 1-14.

Steel tubes of 34 mm. inside diameter and 3 mm. wall thickness were submitted to simultaneous tension and torsional stress. The experiments yielded the following results: under changeable combined tensile and gliding stress, Mises condition of flow does not hold true for steel as Lode's experiments with fixed main axis directions indicated. Even if one tries to eliminate the influence of strain hardening, considerable irregularities in the observed flowing conditions are experienced which seem to point at anisotropies due to the initial deformation. Nevertheless the relationship between stresses and deformations are approximately covered by a new equation with reference to an isotropic continuum. This equation includes as special cases the equations of Saint-Venant-Mises and Prandtl-Reuss. The writers place emphasis on the fact that this newly established equation only represents their test results in an idealized manner and urge a check on other metals and single crystals. EF (3)

The Properties of Nickel-Chromium Alloys and Their Manufacture. A. M. Korolkov. *Tzvetnuie Metallui*, Nov. 1931, pages 1471-1474.

The purpose of the investigation was to obtain alloys possessing a high electric resistance and resistance to oxidation at high temperatures up to 1000° C. The suitability of these alloys for the manufacture of wires and strips was also investigated. A number of alloys available on the market were examined, and for the present work the compositions similar to those of materials made by Heraeus Vakuumschmelze were selected. Melts were made from purest materials available. The alloys prepared analyzed from 61 to 84% Ni, 9 to 22% Cr, 10 to 22% Fe and 1.7% Mn. Other impurities were low. The loss of Cr was as high as 15 to 23%. Microstructure of all alloys is given. All the alloys were satisfactorily cold rolled into a 5 mm. strip, or wire 2.6 mm. in diameter. The wires were then annealed at 950°-1000° C. and drawn to 2 mm. These were annealed again and drawn to 1.5 mm. Mechanical properties of the alloys are given. Tests showed that the electric resistance, temperature coefficient and resistance to oxidation at high temperatures render the alloys suitable for use in heating coils, the ternary Ni-Cr-Fe alloys being the best. Details are given in tables, diagrams and photomicrographs. BND (3)

Properties of some Silico-Manganese Steels. G. Burns. *Foundry Trade Journal*, Vol. 46, May 19, 1932, page 308; *Rolling Mill Journal*, Vol. 7, No. 1, 1932, pages 33-34; *Engineering*, Vol. 133, May 27, 1932, pages 621, 643-644; *Iron & Coal Trades Review*, Vol. 124, May 6, 1932, page 757.

Mechanism of Deformations in Gray Iron. J. W. Bolton. *Transactions American Society for Testing Materials*, Vol. 32, Pt. 2, 1932, pages 477-491.

Susceptibility to permanent deformation in gray cast Fe is found to be dependent on the size and distribution of graphite flakes as well as on their amount. Room-temperature creep tests indicate that gray irons do not creep at room temperature when loaded to 80% of their tensile strengths. This suggests that although gray Fe possesses no apparent true proportional limit (because of the permanent set phenomena) the elastic limit (or more accurately the limiting stress at which statically loaded bars will not "flow" and rupture) is somewhat above 80% of the tensility and probably approaches it rather closely. Progress in the Manufacture of Heat Resistant Steel. (Fortschritte in hitzbeständigen Stahl.) Th. Hoffmann. *Korrosion*, supplement to *Chemische Apparatur*, Vol. 19, June 25, 1932, pages 21-22.

Alloying with Al and Cr makes steel more heat resistant without appreciably changing its mechanical properties. Ferrite-pearlite steels are made heat resistant by adding Al, which reduces the rate of gas diffusion into the steel. "Sicromal" 8, 9, 10, and 12 are recommended for temperatures of 800°, 900°, 1000° and 1200° C. respectively. BER (3)

The Flexibility of Corrugated Pipes under Longitudinal Forces and Bending. L. H. Donnell. *Transactions American Society of Mechanical Engineers*, Vol. 54, June 15, 1932, Applied Mechanics, pages 69-75.

Expansion bends of steam lines or applications where the maximum longitudinal or bending flexibility is required are made of pipes with circumferential corrugations. The longitudinal flexibility is calculated for several types of corrugations, and from this analysis a "reduced modulus of elasticity" is derived by which corrugated pipes can be calculated as if they were smooth; this same modulus is suggested for use also in calculating the bending of corrugated pipes. The full theoretical derivation is given for V-shaped and for semicircular corrugations. Ha (3)

Some Mechanical Properties of Cast Iron. (Considérations sur quelques propriétés mécaniques des fontes.) J. R. Maréchal. *Revue Universelle des Mines*, Series 8, Vol. 8, Aug. 1, 1932, pages 92-97; Aug. 15, 1932, pages 117-123.

A New Theory of Corrosion of Alloys. (Eine neue Theorie der Strukturkorrosion.) G. Akimow. *Korrosion und Metallschutz*. Vol. 8, Aug. 1932, pages 197-205.

1 The electrochemical theory of corrosion is broadened to include alloys. The nature and location of the attack is attributed to differences in potentials resulting from: positions of molecules in the space lattice, grain boundaries, heterogeneity produced by presence of solid solutions or intermetallic compounds and physical inhomogeneity. In different types of solutions the polarity of one particle with respect to another may be reversed. Film formation may also alter the potentials. In any heterogeneous alloy some points become anodic and some cathodic. A scheme is presented for the prediction of anodic and cathodic areas. If
2 a series of connected electrodes I, II, III, IV . . . . N, is present whose potentials in a certain electrolyte are V_1, V_2, V_3, V_4 and V_n and if $V_1 < V_2 < V_3 < 4 \ldots < V_n$ an electrode X will become the external member of the series. When $V_n - X_x > V_x - V_1$, X becomes an anode and vice versa. The electrode X divides the series into 2 parts, cathodes to the left and anodes to the right when $V_n - V_x = V_x - V_1$. Solving this equation $V_x = \frac{V_n + V_1}{2}$. Increasing the anodic areas does
3 not increase corrosion while the reverse is true for cathodic areas. A few experiments with Al alloys containing Cu or Zn give an indication that the theory is valid. Alloying Al with Zn reduced the chemical resistance of the Al. The corrosion phenomena are explained by the new theory. The effectiveness of Mg additions to Al-Cu alloys in preventing intercrystalline attack is also explained by this theory. However, as yet the necessary data to establish firmly the theory of "Strukturkorrosion" are very meager and the author promises further results in a later publication. BER (4)

Protection of Al Alloys by Means of Metals Sprayed on by the Schoop Process. (Korrosionsschutz von Aluminiumlegierungen mittels metallischer Ueberzüge nach dem Schoop'schen Spritzverfahren.) G. Akimow & W. Kroenig. *Korrosion und Metallschutz*, Vol. 8, May 1932, pages 115-119.

4 Plain, riveted, irregularly shaped pieces of duralumin, duralumin-Fe couples and duralumin-stainless steel couples were sprayed with metallic coatings by the Schoop process. The metallic pieces were exposed to a spray of 10% NaCl solution and the mechanical properties determined after 40 days. The sprayed metals showed no decrease in tensile strength or elongation while the uncoated sheets showed a decrease in tensile strength of 13% and in elongation of 24.5%.
5 Cd-Zn coatings kept a good appearance. Zn coatings showed signs of deterioration. Al sprayed upon Fe-Duralumin couples did not afford good protection. Cd coatings were not very satisfactory for couples. An alloy of 83% Cd and 17% Zn proved most satisfactory and also afforded electrochemical protection to duralumin in Black Sea H_2O. Immersion tests were made in the Black Sea. Zn coatings suffered less deterio-
6 ration than in salt spray. Al coatings were subject to localized attacks. Uncoated duralumin was quite severely attacked. Zn and Al afford electrochemical protection to duralumin; Cd does not, particularly if the structure is riveted. Unprotected duralumin was subject to great deterioration in tensile strength and elongation. Cd-Zn coatings are recommended for duralumin or metallic couples subjected to a casual contact with sea H_2O. For submerged pieces Cd-Zn also seems best. Pure Cd is ineffective. Al can also be used but it must be extremely pure. Zn is the least satisfactory. BER (4)

Recent Investigations on the Atmospheric Corrosion of Cu. (Neuere Untersuchungen über die atmosphärische Korrosion von Kupfer.) W. H. J. Vernon. *Korrosion und Metallschutz*, Vol. 8, June 1932, pages 141-147.

7 In order to determine the effect of SO_2 on the patina formed on Cu in the atmosphere, experiments were conducted in which plates of Cu and Cu containing 0.45% As were exposed in the laboratory to air containing 0.1-10% SO_2 at relative humidities of 50-99%. Weight increase-time curves were of the exponential form. Between 0.0 and 1.0% SO_2 a maximum was reached at 0.5% SO_2 and a minimum at 0.85%. Above 1% SO_2 the weight increased with the SO_2 concentration. The critical humidity apparently lay between 63 and 75%. Far more corrosion took place when the critical humidity was exceeded. Below 0.85% SO_2 the
8 corrosion products were $CuSO_4 \cdot x\ Cu(OH)$; x decreasing as the % SO_2 increased. Above 0.85% SO_2 corrosion products were $CuSO_4 \cdot y\ H_2SO_4$; y increasing as the % SO_2 increased. At 0.85% SO_2 the corrosion product was $CuSO_4$. The $CuSO_4$ being washed away when corrosion occurred in the atmosphere the residual product became more basic with time. The corrosion product on high conductivity Cu was very hygroscopic. The presence of 0.45% As reduced the hygroscopicity of the corrosion product and hence the corrosion rate, and more as the time of exposure was increased. CO_2
9 produced no discoloration. SO_2 caused the green patina found in densely populated regions. However, no sulphite was found in the corrosion product and hence the author believes that the Cu catalyzed the oxidation of SO_2 to SO_3. These laboratory experiments confirmed the author's previous contentions that SO_2 was the cause of the green patina and that CO_2 was relatively unimportant in its development. BER (4)

Effect of Properties of Water on the Construction of Hot Water Storage Tanks. (Einfluss der Eigenschaften des Wassers auf den Bau von Heisswasserspeichern.) S. Ottenstein.
10 *Elektrizitätswirtschaft*, Vol. 30, June 1931, pages 357-359.

After 10 years experience on electric hot water tanks, it has been found that Sn-plated Cu furnishes the best material in regard to corrosion resistance. Riveting of the Cu-shells yielded the best results and electrodeposition of Sn has been generally adopted. EF (4)

Corrosion of Oil Containers. (Zur Frage der Korrosion von Transport- und Lagerfässern der Treib-, Heiz- und Schmieröle.) FRANK. *Erdöl und Teer*, Vol. 8, Jan. 15, 1932, pages 12-13.

Vessels carrying highly refined oils show after relatively short service periods marked corrosion attacks, which require expensive repair work. The writer strongly warns against the utilization of Zn as a protection means for Fe, since galvanized vessels displayed extreme corrosion effects. Oil does not dissolve the artificial resin Bakelite and probably not shellac either. Both products however are rather brittle and show an expansion coefficient different from Fe. EF (4) 1

The Determination of the Porosity of Tin Coatings on Steel. D. J. MACNAUGHTAN, S. G. CLARK & J. C. PRYTHERCH. *Iron & Steel Industry & British Foundryman*, Vol. 5, June 1932, page 332.

Method of test involves submerging sample in hot water of suitable purity for several hours and examining the number and distribution of very adherent and easily visible rust spots formed at the pores. The pH value of H_2O should be 4.5 to 7, the temperature 95° C. and time of immersion 6 to 8 hours. CHL (4) 2

Total-immersion Tests. F. N. SPELLER, *et al. American Society for Testing Materials Preprint* 12, 1931, pages 6-10. 4

Tabulated data are given on the failures of sheets of ferrous materials immersed in sea water at the Key West Navy Yard and at the Portsmouth, N. H., Navy Yard. The acid-immersion tests, undertaken to show whether the immersion of Fe and steel sheets in 20% H_2SO_4 gives results comparable to those of atmospheric corrosion tests, show that there is no correlation between these 2 types of tests. The acid test conducted by the procedure followed by the committee is not capable of consistent repetition. The data from such an acid test should not be used to forecast the relative life of ordinary ferrous materials in the atmosphere. Ha (4) 5

Method of Pretreatment for the Production of Corrosion Resistant Coatings for Difficultly Workable Materials. (Die Vorbehandlungsmethode zur Herstellung korrosionsbeständiger Ueberzüge bei schwer zu verarbeitenden Materialien.) A. STEIN. *Korrosion und Metallschutz*, Vol. 8, Apr. 1932, pages 89-91.

A method of pickling is described which permits electroplating of ferrous alloys which are difficultly plated because of oil, non-homogeneous characteristics, etc. A short treatment of the base metal with a mixture of oxalic acid and HCl followed by a secondary pickle in a mixture of acidulated $FeCl_3$ and $Fe(NO_3)_3$ renders the surface free from impurities and permits the deposition of a uniform coat of metal. BER (4) 6

Film-reactions. The Corrosion of Metals. (Schichtreaktionen. Zur Frage der Korrosion der Metalle.) LEIF TRONSTAD. *Zeitschrift für Metallkunde*, Vol. 24, Aug. 1932, pages 185-191.

Galvanic cell theories of corrosion are briefly reviewed. It is emphasized that the determining factor is not the potential difference of the primary local elements but the electromotive force of the *reactions* proceeding at the anodes and cathodes. The effect of local elements can best be studied by direct observation under the microscope. Upon the surface of an Al sheet (0.3% Si, 0.3% Fe) were placed drops of 3 gelatine solutions to each of which had been added separate indicators sensitive in the ranges pH 5.4-7.0, 6.1-7.7, 7.0-8.6 and the solutions then neutralized. These solutions slowly attacked the Al sheet, producing (at different rates) first H bubbles at the points of attack and an acid reaction in the medium nearby, and subsequently a precipitate—probably Al hydroxide—and a general etching attack; in no case were alkaline points of attack found. The formation of acid is attributed to inclusions in the Al. Similar observations were made on Fe (0.01% Fe, 0.002% P, 0.036% S, 0.02% Mn) with a phosphate buffer added to the gelatine. In this case gas bubbles were found not to originate at inclusions; the corrosive attack proceeds under the influence of local galvanic cells. RFM (4) 7 8

Standardization of Corrosion Tests for Light Alloys. (Normalisation des Essais de Corrosion des Alliages Légers.) *Revue de l'aluminium et de ses applications*, Vol. 9, Jan.-Feb. 1932, pages 1650-1654.

A description of the methods of corrosion testing developed and standardized by the European Aluminum Association. These tests are: (a) Mylius, (b) Modified Mylius, (c) Salt spray, (d) Continuous dipping, (e) Dipping at regular intervals. The Mylius test consists in the measurement of the heat evolved per unit time when the alloy comes in contact with dilute HCl. In the case of metals of a high degree of purity the volume of hydrogen evolved per unit time is measured. The modified Mylius test consists in the measurement of the change in tensile strength and elongation after several different periods of dipping in a solution of 0.5 *N* NaCl in water containing 0.1% of pure H_2O_2. AH (4) 9

Loosening of Rusted Parts. (Ablösung verrosteter Teile.) *Oberflächentechnik*, Vol. 9, Aug. 16, 1932, page 168.

According to German patent No. 523071 parts which have become so tight by rust that they cannot be loosened and taken off, can be removed easily by applying methylhexaline and other organic solvents obtained by hydration; these penetrate readily into the rusted parts and loosen them. Ha (4) 10

UNIVERSAL CORROSION-RESISTANT ALLOY

supplied as rough or finished castings

Particularly effective against the sulphur acids and compounds, ILLIUM likewise withstands other corrosives, both acid and alkali, to a degree equalled by few materials. Also resistant to heat, wear, impact and torque. It machines readily, takes high polish, is easily welded.

ILLIUM has been in successful use for more than 15 years. Its chemical and physical characteristics are known. Its advantages and limitations clearly defined. Its record is proof of its value.

RECOMMENDED FOR

Agitators	Filter Parts
Bobbins and Holders	Instrument Cases
Bombs	Kettles
Bolts and Nuts	Machine Parts
Buckets	Nozzles
Crucibles	Pipe Fittings
Dipping Baskets	Pump Parts
Fans	Racks

Corrosion Plays a Major Part in the Cooling of Radiators. Wm. H. Wilson. *Automotive Industries*, Vol. 66, Mar. 1932, pages 457-458. Effect of oxidation corrosion on the Fe and steel parts of the automobile cooling system was studied. After a discussion of the theory of corrosive oxidation the writer points out that the same general conditions occur in the corrosion of other cooling system metals such as Cu, solder and brass. Since the corrosion products of these metals are finally precipitated as oxides or hydroxides, the term "corrosive oxidation" has been used. Average corrosion loss in mg./200 hrs./12 in.^{2} area, the test metals not being in electrolytic contact with any other metals, are:

Test Metal	Distilled Water Not aerated	Distilled Water Aerated
Iron	55	580
Solder	5	12
Copper	1	22
Brass	2	28

These and other test data, as well as the theory of corrosion, show that aeration is the greatest single factor involved in cooling-system corrosion and the formation of rust. In the absence of aeration, corrosion of metals can proceed only until a protective film of H_2 is formed, after which the attack is negligible. DTR (4)

Acid Corrosion Resistance of Paint Coatings on Phosphatized Iron. (Die Säurebeständigkeit von Anstrichen auf phosphatiertem Eisen.) Fr. Kolke. *Farben Zeitung*, Vol. 36, Sept. 26, 1931, pages 2235-2238.

Corrosion tests are reported which were made with phosphatized and plain Fe sheets dipped into 6 different lacquers and then exposed to the attack of the following media: acetic acid, H_2SO_4. H_3PO_4 and HCl. Concentration was 3% and the testing times amounted to 24, 48, 72, 120 and 168 hours. Disregarding the results in acetic acid, the durability of acid proof lacquers on phosphatized carriers was not improved but rather impaired. The inferior acid resistance of lacquer coatings on parkerized steel is ascribed to the permeability of the coating and to the solubility of the phosphates in the acids applied. EF (4)

Regarding the Protection of Mg Alloys against Corosion by Chemical Oxidizing Processes. (Ueber den Schutz von Magnesiumlegierungen gegen Korrosion mittels Beizverfahren.) W. O. Kroenig & G. A. Kostylev. *Korrosion und Metallschutz*, Vol. 8, June 1932, pages 147-151.

Numerous methods for oxidizing Mg and its alloys were investigated. The best results were obtained when using a solution containing 4 parts $K_2Cr_2O_7$, 18 parts HNO_3 and 100 parts H_2O by weight at 80° C. The addition of nitrates improves action of the solution and permits operation at room temperature. The action of the pickle is not the same for all alloys. The stability of Mg is not influenced; alloys containing Al show the best results. The best results are for sea H_2O. No practical value is evident in tap and distilled H_2O. The resistance against atm. corrosion is considerably increased. The solution loses its effectiveness during use. 10 liters should be used to treat not more than 1 m.^{2} of surface. BER (4)

Studies on the Influence of Heating Period, Temperature, Gas Velocity and Atmosphere on Iron Loss. (Untersuchungen über den Einfluss von Liegedauer, Temperatur, Gasgeschwindigkeit und Atmosphäre auf den Eisenabbrand.) Wilhelm Schroeder. *Archiv für das Eisenhüttenwesen*, Vol. 6, Aug. 1932, pages 47-54.

1 Report 166 of Heat Section of Verein deutscher Eisenhüttenleute. Losses on heating were determined in a test pusher furnace 360 x 360 x 400 mm. heated with different fuels, illuminating gas, oil, or coke. Ingot steel of uniform composition, containing 0.34% C, 0.28% Si, 0.87% Mn, 0.07% P and 0.005% S was used for the charge, and dimensions of the ingots were 25 x 25 x 60 mm. Temperature range explored was 900° to 1100° C. Test results were plotted on a series of curves for the different factors studied. The most important results are summarized herewith. Temperature strongly influences the amount of loss on heating. A temperature rise from 900° to 950° C. gave a 25% higher loss. With a rise from 900° to 1000° C. the loss was 100% higher. The Fe loss on heating is small up to a temperature of 900° C. on the top surface of the ingot. In the operation of a pusher furnace it is evident that a rapid rise of ingot surface temperature up to 900° C. is desirable, providing that this procedure is possible without producing cracks in the ingots. A considerable difference lies in the kind of furnace atmosphere, be it oxidizing or reducing. Above 900° C. a reducing atmosphere should be used by all means. Illuminating gas, with its high water vapor content (21.2%), and excess air gives better ignition than coke with high CO_2-content (20.5%). From this it follows that water vapor or steam gives a stronger oxidizing action than CO_2. On the other hand illuminating gas with insufficient amount of air decreases the loss more than does coke, which is to be attributed to the stronger reducing action of H as against that of CO. Thus illuminating gas is the best fuel to use, since with its high percentage of H, even with small air deficiency, it yields the lowest losses. If a reducing flame is maintained on the principal burner of a pusher furnace, the unburned gases must be burned afterwards in the back part of the furnace by means of supplementary air or an added burner. In this event not only fuel losses are avoided, but also an ignition layer is set up with an oxidizing atmosphere in the back of the furnace surrounding the ingot, which in opposition to a reducing atmosphere adheres very loosely and the top surface of the charge does not become rough. Then the reducing atmosphere of the main burner can no longer cause any breaking down of the smooth surface of the charge. The benefits of the 2 methods, (1) excess air—smooth surface of the furnace charge, and (2) lack of air—small Fe loss—are tied up with each other. The various positions of the ingot sides to direction of the flame, flame radiation, or within the zone of the flame are all without effect on the loss during heating. The loss in g./cm.^{2} for surfaces surrounded by gases is the same for all sides. A varying rate of flow of waste gases does not affect the loss. DTR (4)

Contribution of the Knowledge of the Protective Action of the Oxide Films Formed on Steel by Scaling. (Beitrag zur Kenntnis der Schutzwirkung der beim Zundern auf Stahl gebildeten Oxydschichten.) Hjalmar von Schwarze. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund*, Vol. 2, No. 12, 1932, pages 263-277.

6 The object of this investigation was to find the conditions under which steels at high temperatures form on their surface such oxide film that scaling is effectively prevented. The oxidizing velocity was determined by means of the temper colors; the thickness of the oxide film and composition of the scale was examined. The ternary system Fe-Cr-Al was investigated up to 20% of each component with regard to scaling up to 1200° C. 2 different forms of scale were observed: white scale, which is very dense, adheres firmly and protects well against further scaling, and black scale which does not protect. The Al and Cr content determine which kind of scale is formed, pure Al alloys or 7 those with predominant Al content form white scale. This scale consists mainly of alumina and protects even in very thin films; steels with white scale remain practically unchanged at very high temperatures and can be used as heat-proof steels. Black scale consists mainly of Cr and Fe oxides. Higher Cr contents give a protection but to a much lesser degree than the Al steels, and the protective action is good only up to 900° C. Test methods, ternary diagrams and results are described in full and the analyses of steels investigated are given. Ha (4)

The Effect of Hydrogen Sulphide on the Corrosion of Iron by Salt Solutions. S. C. Britton, T. P. Hoar & U. R. Evans. *Iron & Steel Institute, Advance Copy* No. 2, Sept. 1932, 9 pages.

8 Small additions of H_2S or Na_2S (less than 5 parts per million) added to KCl solution accelerated the total attack of electrolytic Fe and mild steel partially immersed. A study of the mechanism of attack indicated that the increased general attack was due to a stimulation of the anodic reaction. The intensity of attack was diminished by the sulphide because the area of attack was extended. 11 references. JLG (4)

Corrosion and Nucleus Formation. (Korrosion und Keimbildung.) H. Cassel. *Korrosion und Metallschutz*, Vol. 8, May 1932, pages 113-115.

9 A theoretical discussion of the probable importance of nucleus formation on anodic and cathodic reactions and the rapidity of metal dissolution. No experimental data. BER (4)

The Rate of Solution of Thallium in Acids. (Lösungsgeschwindigkeit des Thalliums in Säuren.) M. Centnerszwer. *Zeitschrift für Elektrochemie*, Vol. 37, Aug-Sept. 1931, pages 603-610.

Tl dissolves readily in HNO_3 with little generation of H_2. After an induction period, the rate of solution proceeds according to Boguski's rule. The rate of solution increases 10 with increasing strength of HNO_3 to 0.25 *N* and then decreases. The temperature coefficient increases with temperature. Tl dissolves slowly in H_2SO_4 and in HCl. The rate of solution is nearly independent of the acid concentration. The rates of solution in 2 *N* HNO_3, H_2SO_4 and HCl are 428: 1.78:1 respectively. Ha (4)

The Most Important Announcement in Years for Hydrochloric Acid

DURICHLOR

DURICHLOR is a new acid-resisting alloy, developed by THE DURIRON COMPANY, which is almost entirely resistant to Hydrochloric Acid at all concentrations and at all temperatures, up to the boiling point!

DURICHLOR fills the need for an alloy with satisfactory chemical resistance, good heat transfer properties, good physical characteristics, and is commercially practicable from the viewpoint of cost.

All types of equipment now made in *Duriron*—pumps, valves, pipe and fittings, exhaust fans, circulating jets, ejectors, and other handling equipment—are also being made in DURICHLOR.

Samples of DURICHLOR are available for testing—ask to have our representative call. He has further information which will be of interest to you.

Corrosion of Lead. Its Causes and Remedies. *Electrical West.* Vol. 68, May 15, 1932, pages 457-461.

Report of Subcommittee on Lead Corrosion Underground Systems Committee, Engineering Section, Pacific Coast Electrical Association, dealing with a laboratory investigation of chemical corrosion of Pb. Describes method of testing and tabulates various tests. These were made to conform as nearly as possible to practical field conditions. Observations made upon surface exposed to air indicate that mechanically stressed Pb shows increased corrosion. Direct current corrodes Pb readily, the Pb becoming charged like storage-battery plates. Tests show that use of bare Cu neutrals and bare Cu wire for cross-bonding in water-filled manholes is conducive to corrosion. At end of 2 months, galvanic current between a Cu and a Pb electrode, each 18" long and 1" in diameter and half submerged in electrolytic H_2O was 0.7 milliamp. This would prove quite destructive. At end of 2 months galvanic potential between Fe and Pb was 0.04 volts and 0.25 milliamp., in favor of the Pb. For the same period, galvanic potential for Zn to Pb was 0.13 volts and 0.75 milliamp., in favor of Pb. Tests are still in progress. MS (4)

Corrosion of Tin Plate by Greened Food Products. (Korrosion des Weissbleches bei gegrünten Konserven.) P. Nehring & E. Nehring. *Konserven-Industrie,* Vol. 18, Mar. 1931, pages 199-201; Apr. 1931, pages 214-215.

Experiments were carried out to throw light upon the frequently encountered corrosion of cans used for greened food products. It was established that the corrosion of the lacquered and unlacquered tin plate is due to the addition of $CuSO_4$ which is required for the greening process. The Cu attacks the tin plate. Pitted areas are developing and the Fe is exposed. Either the remaining Cu or the fruit acids present will cause rapid perforation of the Fe. EF (4)

Discussion on the Corrosion Theory. (Erörterungen zur Theorie der Korrosion.) E. Liebreich. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 160, June 1932, pages 211-224.

Pursuing previously published research work a series of new tests yielded evidence against the differential aeration theory of Evans. All experiments indicate that, on account of the effect of local elements, the corrosion products originated determine the corrosion appearance irrespective of the enobling action of O_2. With respect to the corrosion of plates partly or wholly submerged in liquids, an O_2 concentration gradient along the plate does not play any role. Especially in case of partly submerged plates, the reason for the more pronounced unattacked zone is not the greater amount of aeration, but the current phenomena. The surface tension probably exerts an additional influence. In an atmosphere saturated with water vapor and containing O_2 no central corrosion spot occurs in the drop test if the experiment is carried out in such a manner that the drop does not spread out. Stirring of the liquid also does not produce a central etching picture on Fe plates. Only the course of the corrosion products determines the appearance of the corrosion picture. EF (4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Recrystallization and Crystal Recovery after Cold-Working of Pure Aluminum and Several Age-Hardening Aluminum Alloys of an Aluminum-Copper Base. (Ueber die Rekristallisation und Kristallerholung von Rein-aluminium und einigen aushärtbaren Aluminiumlegierungen auf Al-Cu-Basis nach Kaltverformung.) H. Bohner & R. Vogel. *Zeitschrift für Metallkunde,* Vol. 24, Aug. 1932, pages 169-175. The following alloys were studied: pure Al, 0.19% Si, 0.23% Fe; (I) 1.09% Si, 0.24% Fe, 4.29% Cu, 0.55% Mn; (II) 0.18% Si, 0.23% Fe, 5.56% Cu, 0.61% Mn; (III) 0.50% Si, 0.22% Fe, 4.21% Cu, 0.43% Mn, 0.45% Mg; (IV) 2.23% Si, 0.40% Fe, 4.20% Cu. In pure Al critical grain growth takes place at 1.5% cold-rolling on heating to 500° C. for 20 min.; for alloy I at 5%, alloy II at 6%, alloy III at 5%, alloy IV at 2%. Al recrystallizes (after cold-rolling) at the lowest temperatures, then follow in order of higher temperatures, alloys IV, I and III, II. Recrystallization depends not only upon chemical composition, heating temperature, time of heating, but also upon the thermal and mechanical treatment prior to recrystallization, as temperature of deformation, type of deformation, deformation velocity, degree of deformation, and by the size and orientation of the original grains. Under certain conditions the surface offers greater resistance to recrystallization than the interior. The range of "critical grain-growth" is greater in pure Al than in the Al-Cu alloys studied; increase in Si in the Al-Cu alloys lowers the recrystallization temperature and the critical deformation. Increase in Mg has no effect whereas increase in Mn increases the critical deformation. Lüder lines, observed in the Al-Cu alloys, act as seats for recrystallization, giving recrystallized grains oriented along the Lüder lines. Crystal recovery is dependent upon the thermal and mechanical treatment prior to deformation and can be influenced by small variations in composition. RFM (5a)

Prevention of Recrystallization by a Preliminary Short Annealing. A. A. Bochvar. *Tzvetnuie Metallui,* No. 5, May 1931, pages 587-594. The author investigated the effect of preliminary short annealing on grain growth after cold deformation in metals which in service are liable to heating above recrystallization temperatures. The tests were made on 2 grades of Sn, 99.8 and 99.9 pure. First, the rate of grain growth of cold worked samples (Brinell impressions) was determined at temperatures from 100° to 180° C. In the second set of experiments the cold worked samples were first given a short anneal and then heated for a long time at temperatures slightly lower than the preliminary anneal. It was found that a preliminary anneal for a few seconds at temperatures 15° C. or more higher than the (possible service) temperature of the long annealing is sufficient to prevent any further appreciable grain growth. The grain size after preliminary annealing was found to increase somewhat, but it always was less than that of specimens heated for a long time without the preliminary anneal. Heating for 2 - 10 seconds at 165° or 180° C. was found sufficient to prevent further grain growth at 150° C. These results were verified by further experiments. Detailed data are given in tables, graphs and photographs. BND (5a)

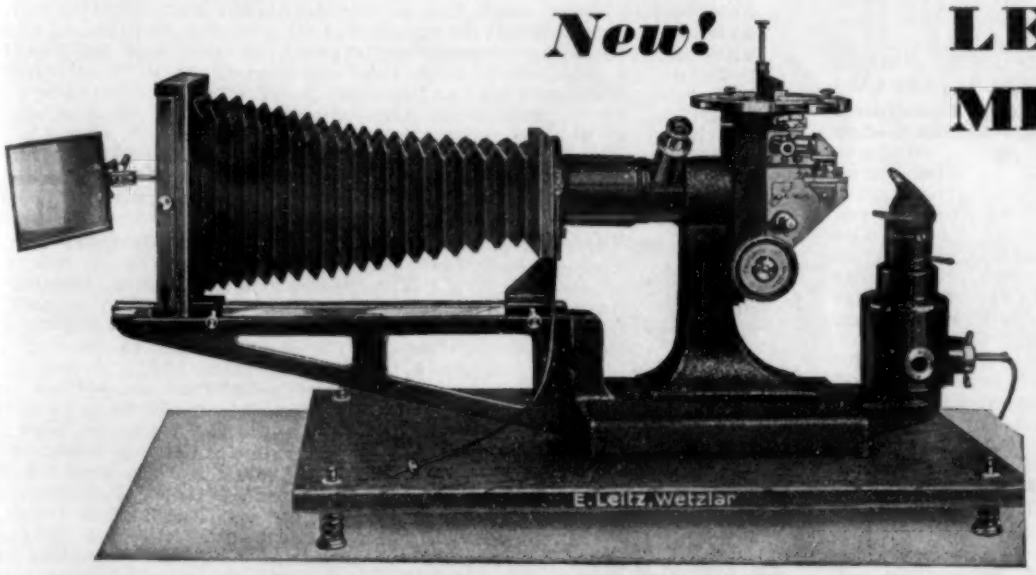
On the Rates of Reactions in Solid Steel. Edgar C. Bain. *Transactions American Institute Mining & Metallurgical Engineers, Iron & Steel Division,* Vol. 100, 1932, pages 13-46. This is the Ninth Annual Henry Marion Howe Lecture, delivered in Feb. 1932. Previously reported work had shown that in C and low-alloy steels the rate of decomposition of austenite was a maximum between 600° and 500° C. Rates of reaction were determined by microscopic examination of quenched samples or by the dilatometer. Decomposition-time curves are shown for several Mn steels containing 0.55% C at temperatures of 525° and 315° C. Also for Ni steels containing 0.55% C at 480° and 315° C. The rate of reaction decreased rapidly as the temperature was lowered. The decomposition-time curves closely agree with "first-order reaction curves" except that they are shifted forward along the time axis, the rate is not a maximum for zero decomposition, and all austenite is decomposed in finite time. Increased amounts of Mn and Ni decreased the rate of decomposition, but Mn was much more effective in this respect than Ni. Austenite, ferrite and carbide were found to be stable in some alloys in a certain temperature range as proved by the decomposition-time curves and by microstructures of pearlitic and austenitic samples of the same steel held in this range. In some of the Ni steels graphite and not carbide was the end product, but in all cases cementite first formed and then was converted to graphite, provided any graphite was formed. An austenitic Mn steel was partially transformed to martensite by cooling in liquid air. On reheating this steel to 525° C. the carbides were immediately precipitated from the martensite, while many hrs. were required for appreciable decomposition of the austenite. As this experiment proved that the rate of decomposition of martensite at elevated temperatures was much greater than the rate of transformation of the austenite, it was concluded that martensite was *not* an intermediate stage in the formation of pearlite. Carbide absorption rates at quenching temperatures and the rates of carbide growth at tempering temperatures are briefly discussed. JLG (5a)

The Use of Polarized Light in the Study of Metal Sections. (Über die nutzanwendung des polarisierten Lichtes bei der Untersuchung von Metallschliffen.) M. F. von Schwarz. *International Association for Testing Materials, Zurich Meeting, 1931,* Vol. 1, 1932, pages 508-517. Striking micrographs of Si Cu, Cu P and other alloys showing the same fields with ordinary illumination and with polarized light. Details of structure not revealed by ordinary light come out when crossed nichols are used. Characteristic colors are shown by different phases, as is illustrated by a couple of color photographs. See also "The Micro-optical Investigation of Non-ferrous Alloys by Polarized Light," *Metals & Alloys,* Vol. 3, Aug. 1932, page MA 239. HWG (5a)

The System Iron-Cobalt-Carbon. (Das System Eisen-Kobalt-Kohlenstoff.) Rudolf Vogel & Werner Sundermann. *Archiv für das Eisenhüttenwesen,* Vol. 6, July 1932, pages 35-38.
The phase diagram for Fe-Co alloys with amounts of C up to 5% was studied by the usual cooling curves, structure
1 examinations, and magnetometric measurements. 3 classes of crystals separate out: ternary α-solid solution, ternary γ-solid solution and graphite. Primary cementite precipitation was not found for the rates of cooling used, 1° to 2°/sec. The eutectic consisted of ternary solid solution and cementite or graphite. The ranges, in which the cementite or graphite
— eutectics occur, were divided by a transition zone, in which both phases existed in common. Alloys in this range of concentration easily change over from the graphitic to the cementitic solidification through slight variations in the rate of cooling or in the pressure. These conditions are well
2 known in the case of reversible chilled castings. The relation of the hardness characteristic of Co-steels to their composition was determined for a definite rate of cooling. The transformations in the solid state for alloys up to 80% Co finally produces pearlite, which consists of binary α-solid solution and cementite or graphite. The γ-solid solution is
— stable down to room temperature for the samples containing 80 to 94% Co. The magnetic transformation of Fe is caused to take place at higher temperatures by Co. The magnetic conversion was observed in alloys up to 70% Co. For alloys up to 10% Co and 2% C the range within which martensite occurs was determined for a cooling rate of 65°/sec. Aus-
3 tenite, sorbite and troosite were not observed. DTR (5a)

Mechanical and Magnetic Precipitation Hardness of Iron-Cobalt-Tungsten and Iron-Cobalt-Molybdenum Alloys. (Mechanische und Magnetische Ausscheidungshärtung der Eisen-Kobalt-Wolfram- und Eisen-Kobalt-Molybdän-Legierungen.) Werner Köster. *Archiv für das Eisenhüttenwesen,* Vol. 6, July 1932, pages 17-23. Report 181 of Committee on Materials of Verein deutscher Eisenhüttenleute. In the investi-
— gation of Fe-Co alloys with increasing additions of W or Mo, it was demonstrated that the variation in hardness with the annealing temperatures depends on the original struc-
4 ture of the alloy, that is, whether it is a representative ferrite, austenite or martensite type. By noting the change in specific gravity, electrical conductivity, and magnetic saturation it was observed that the annealing process for ferrite and austenite alloys depended solely on the precipi-
— tating out of supersaturated solid solutions of the series Fe_3W_2-CoW or Fe_3Mo_2-CoMo. In the case of martensite alloys there occurred the added transformation of residual austenite, which was established at temperatures somewhat lower than the precipitation. The hardening of ferrite alloys is accelerated if supersaturated α-solid solution is produced
5 by cooling from the γ-phase. The hardness numbers increase for all 3 structure states with increasing amounts of Co, W, or Mo. The hardness was measured up to 70 on the Rockwell-C-scale. The magnetic hardening of α-alloys produced in the course of separation takes place at only slightly higher temperatures than the mechanical hardening. Widen-
— ing of the induction loop involves appreciable changes. In the maximum case a rise in coercive force was observed 75 times higher than its value in the cooled condition. The coercive force in this case was 350 Oersted at 7300 gausses remanence. With increasing amounts of W, Mo and Co, the
6 coercive force increased. Remanence decreased with increasing W or Mo, and increased with increasing Co. The martensite alloys after being hardened by precipitation are suitable as cutting and machining alloys, the ferrite alloys as permanent magnets. Due to their special metallographical differences from alloyed C steels, together with their par-
— ticular properties already outlined, new fields are opened up for these C-free alloys in the manufacture and use of cutting tools and permanent magnets. DTR (5a)

On the Structural Constituents of Chromium Steels. Takejiro Murakami & Kazue Hatsuta. *Tetsu to Hagane,* Vol. 18, Apr. 1932, pages 399-405. In low Cr-high C steels, the magnetic
7 transformation below 200° C. takes place in 2 steps, which were previously attributed to existence of 2 carbides, i.e., cementite and α-double carbide by one of the present writers. By annealing and slow cooling the specimens, the change takes place in one step. This transformation tem-
— perature in well annealed specimens, gradually decreases, as the Cr content increases. The corrodibility of the carbide existing in low Cr steels by boiling picrate solution gradually decreases, as the Cr content increases. From these facts it is concluded that the Cr dissolves in cementite forming a θ-solid solution, and the α-carbide is not a double
8 carbide. β-carbide previously proposed by one of the present writers is also the θ-phase dissolving much Cr and not a double carbide. The corrodibility of carbides by several etching reagents, and the X-ray spectrum of carbides in many alloys of this system were investigated. In this sys-
— tem there exist 2 other carbides, η- and ε-phases, besides θ-phase, above described. The η- and ε-phases are solid solutions dissolving Fe in trigonal and cubic carbides, Cr_7C_3 and Cr_4C, respectively and not double carbide, confirming the view of Westgren, etc. From these results a consti-
9 tutional diagram at the room temperature showing the fields in which several phases exist was constructed, that of Westgren, etc. being somewhat modified. TM (5a)



The Growth of Austenite above Ac_1 in Plain Carbon Steels. J. H. Whiteley. *Iron & Steel Institute, Advance Copy* No. 13, Sept. 1932, 12 pages. Hypo-eutectoid steels were heated to
— various temperatures between Ac_1 and Ac_3 and quenched in order to determine the structure at that temperature. Austenite when formed at isolated areas tends to surround the untransformed ferrite, leaving islands of ferrite in a groundmass of austenite. The slower the rate of heating the greater the tendency for the austenite to surround the fer-
10 rite. Mn decreases the tendency of the austenite to surround the ferrite grains. The movement is modified and may be suppressed by a banded structure. The extent of the movement is increased by repeated heatings, provided the intermediate coolings are not too slow. The formation of the
— austenite film causes a drop in the impact value after the steel has been cooled to room temperature. JLG (5a)

Heat Treatment of Ternary Alloys Containing Gold and Nickel. J. S. SHELL. *Journal American Dental Association*, Vol. 18, Aug. 1931, pages 1541-1544. Ni-Au alloys consist, after quenching from 900° C., of homogeneous solid solutions, which disintegrate eutectically after 24 hours annealing at about 420° C. The addition of Cu, Co, or Fe to Ni-Au alloys of medium concentration shifts the disintegration temperatures; this can be of importance for the application of the white gold alloys in dentistry. Ha (5a)

The Kinetics of the Transformation of Austenite. I. Magnetic Studies of Austenite Decomposition. (Zur Umwandlungskinetik des Austenits. I. Magnetische Untersuchungen des Austenitzerfalles.) FRANZ WEVER & HEINRICH LANGE. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung*, Vol. 14, Report 201, 1932, pages 71-84. The transformation of 2 Cr-Ni-steels containing 0.35 and 0.50% C was studied with an improved Wever and Lange magnetometer furnace, the original hookup being outlined in *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, 1930, page 353. The conversion of austenite was determined by the GP- and GS- lines of the equilibrium diagram and their prolongations at low temperatures. The transformation took place in 3 well defined and separate temperature stages. In the first stage between 650° and 500° C. the transformation reactions occurred in a sequence similar to that for slow cooling. In the beginning of the first stage, ferrite alone is precipitated, whereby the C-content of the austenite is increased up to the eutectoid composition. Finally the pearlite conversion sets in and the transformation is terminated. In the second stage between 500° and 120° C., the austenite loses its ability to yield cementite in direct formation. At first the austenite precipitates out supersaturated ferrite, the composition of which is given by the extension or prolongation of the GP-line. This ferrite however breaks down very rapidly into stable, practically C-free ferrite and cementite, which as a nucleus indirectly produces cementite separation from the austenite. In the lower part of the second stage no further cementite is formed from the ferrite on account of insufficient diffusion, while coincident with this the activity for cementite precipitation from austenite is halted. In this temperature stage the C is converted into a form which as yet is unknown, and which is converted by annealing into cementite. In the third stage the austenite is converted into the intermediate form of tetragonal martensite without any alteration in composition, this form being nothing more than the supersaturated ferrite. The precipitation of supersaturated ferrite in the second and third zones always gives a formation of needles. These needles retain their external shape at temperatures below 350° C. for so long a time, that they are actually made visible in structure. However at temperatures above the martensite-point they break down always into the cubical ferrite and cementite or the as yet unknown structure form of C. In the third stage only these needles retain their original tetragonal shape. Upon annealing they are converted readily into the more stable cubical shape along with precipitation of C. 8 references. DTR (5a)

On the Types of Fractures of Metals and Alloys: Part I. Pure Metals and Mono-phase Alloys. ICHIRO IITAKA. *Tetsu to Hagane*, Vol. 18, May 1932, pages 480-489. Fractures of metals and alloys are technically very important. They differ from each other both as to kinds of materials and applied forces. The writer has classified all these fractures into 4 types according to the path and mechanism of rupture. The types for poly-phase alloys may be considered as combinations of those for mono-phase ones. Type 1. Transgranular. Separation occurs along cleavage planes or "Spalt-fläche." Fineness of fracture coincides with grain size. Very rough fracture. Type 2. Transgranular. Slipping occurs along slip planes. Fracture is generally very much finer than grain size, fineness is equal with slip band size. Very fine fracture. Type 3. Transgranular. Breaking occurs along dendrite boundaries. Fineness is quite indifferent to grain size and coincides with dendrite size. Very fine fracture. Type 4. Intergranular. An abnormal fracture breaking along grain boundaries. Fineness coincides with grain size. Very rough fracture. Type 3 was discovered by his experiments. Many common metals and alloys belong to this type, other 3 types being met with rather in rare cases. The reasons for proposing the new type are described in this paper. Test pieces were always broken by bending with shock force. Fractures, when viewed by the naked eye, give a feeling of fineness or roughness which of course is due to the zigzags on the surface. The characteristic features of type 3 are as follows: (a) The width of zigzags which determines the fineness is far smaller than grains but of equal size with dendrites. The fineness of fracture in natural size of α brass is smaller than 1-1/10 mm. The grains are 1 mm. or so wide and 10 mm. or more long while the dendrites are about 1/30 mm. thick and correspond just to the zigzags of the fracture. (b) The path of fracture runs mostly along the trunks and big branches of dendrites, and even when the force acts so as to cross them they project (or sink) a little resulting in both cases the unevennesses of their sizes on the fracture. (c) Dendrites are revealed in most fractured surfaces and contribute directly to the feeling of fineness. They are of equal size with the dendrites shown in the photomicrographs of the polished and etched surfaces. (d) Is the grain size proportional to the dendrite size and consequently proportional also to fineness? That the answer is negative and the fineness is quite independent of grain size was proved by photomicrographs of gun metal ingots cast at various temperatures. Even the specimens of the same grain size give quite different finenesses when the dendrite sizes are different. Besides, specimens of larger grains have finer fracture than specimens of smaller grains when the dendrites of the former are smaller. That the fracture is exceedingly fine as compared with grain size was clearly proved by many photographs. Fracture of large dendrites is coarse and that of small ones is fine. Even different alloys are of the same fineness when their dendrite sizes are equal. These results were confirmed on fractures of steels, various Cu alloys, etc. TS (5a)

New!

LEITZ MICRO-METALLOGRAPH

Simplified Model "MM-2"

Note: The Leitz Darkfield Equipment and the new series of Leitz Objectives (corrected for infinity) are supplied with the Simplified Micro-Metallograph "MM-2."

THE INVERTED MICROSCOPE and Camera of Micro-Metallograph Simplified Model "MM-2" represent a modified as well as simplified construction of the well known Leitz Micro-Metallograph Large Model "MM-1" which is so successfully used for micro-analysis of metals. The purpose of offering the Simplified Model "MM-2" is *to provide at the lowest possible cost an instrument including all essential equipment both in optical and mechanical respects that meets the entire range of practical requirements from carbon-iron alloys to metals of every variety.*

THE NEW INSTRUMENT fulfills a demand which has hitherto existed for micro-metallographic equipment arranged in its construction to meet the efficiency known to exist with the large Micro-Metallograph, however, in price so arranged, that industrial and educational laboratories with a moderate purchasing budget can be accommodated.

Investigations on the Iron-Oxygen System. (Untersuchungen über das System Eisen-Sauerstoff.) H. Schenck & E. Hengler. *Mitteilungen aus dem Institut für Eisenhüttenkunde der technischen Hochschule zu Aachen*, Vol. 11, 1932, 6 pages. See *Metals & Alloys*, Vol. 3, July 1932, page MA 204. Ha (5a)

Advances in Microscopy. F. F. Lucas. *International Association for Testing Materials, Zurich Meeting, 1931*, Vol. 1, 1932, pages 422-444. Common metals absorb so much and reflect so little ultra-violet light that the hopes for greatly improved resolving power by its use have not been fully realized for metallography. Much information in previous publications of Lucas is again given in this article and the 3500 diameter micrographs of martensite, etc. that have appeared in those publications are reproduced. HWG (5a)

The Kinetics of the Transformation of Austenite. II. Dilatometric Studies of Austenite Decomposition. (Zur Umwandlungskinetik des Austenits. II. Dilatometrische Untersuchungen des Austenitzerfalles.) Franz Wever & Werner Jellinghaus. *Mitteilungen Kaiser-Wilhelm-Institut für Eisenforschung*, Vol. 14, Report 202, 1932, pages 85-89. The transformation of a Cr-Ni Steel containing 0.35% C was studied with a modified P. Chevenard differential dilatometer. Results are tabulated for 22 tests giving the rates of transformation and the changes in length of austenite at temperatures varying from 728 to 130° C. At 728 and 660° no conversion was observed in a period of 2 hrs. At 614° C. this change in structure was first evidenced by change in length of test steel. The results plainly corroborate Wever and Lange's magnetic studies on austenite decomposition. Again it was observed that the transformation occurs regularly in 3 well defined temperature stages. Time-elongation curves are shown for various temperatures. 8 references. DTR (5a)

Veining or Sub-boundary Structures. L. Northcott. *Iron & Steel Institute, Advance Copy* No. 10, Sept. 1932, 13 pages. Veining net work was observed in mild steel, wrought Fe, cast Ni, and cast Cu, but not in electrolytically deposited Fe, Ni or Cu. Veining can be removed by quenching from a high temperature. It can also be removed from the surface layers of steel by annealing in H. It is promoted by annealing in air. By certain heat treatments the particles causing the veining can be made to agglomerate. The observations indicated that veining was due to oxide inclusions. They also indicated that the solubility of O in γ Fe was greater than in α Fe, and that the solubility in α Fe decreased with decreasing temperature. The possible influence of O on aging phenomena is discussed and it is concluded that O is not responsible for aging at room temperature as veining is only affected by heating several 100° above room temperature. 8 references. Structure and X-Ray Analysis (5b)

Thermal Behavior of Certain Solid Solutions. E. L. Nichols & Mary A. Ewer. *Journal Optical Society of America*, Vol. 22, Aug. 1932, pages 456-465. Some materials, notably Tb, Pr, U, Eu, showed a certain flash effect when a flame heating the substance was withdrawn. This occurred a definite time after the withdrawal of the flame. This glow took place, however, only if some activating material was present. The spectrum of the flash was investigated; the bands lay generally between 0.510 μ and 0.050 μ. The cause of the phenomenon must be ascribed very likely to a gradual change in the crystalline arrangement of the material. The method of investigation is described in detail. Ha (5b)

Precision Determinations of the Space Lattice Constants of Beryllium. (Präzisionsbestimmung der Gitterkonstanten von Beryllium.) M. C. Neuburger. *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 17, June 1932, pages 285-292. The space lattice dimensions of highly pure Be which contained only traces of Fe, Ba and C (spectroscope) were re-determined by X-ray powder photographs. An accuracy of 0.01% was ascertained due to the utilization of Reglers' calibration method (See *Metals & Alloys*, Vol. 3, page MA 266). EF (5b)

X-ray Interferences on Liquids. Hg, Ga, CCl_4. (Röntgeninterferenzen an Flüssigkeiten. Hg, Ga, CCl_4.) H. Menke. *Physikalische Zeitschrift*, Vol. 33, Aug. 15, 1932, pages 593-604.
The theoretical part of the subject is treated under the following heads: (I) Coherent and incoherent scattering of a single atom; (II) Scattering of liquids composed of single atoms: (III) Scattering of liquid CCl_4. Then the experimental equipment is described in full detail. The X-ray photographs of liquid Hg show distinct minima and maxima in almost periodical succession. Similar intensity curves were gained on Ga, which was studied at 45° C. and in an under-cooled liquid state at 18° C. The m.p. of Ga is 30° C. EF (5b)

X-Ray Investigation for the Change of Direction of Crystal Axes During an Allotropic Change of a Substance. Hikoroku Shoji. *Kinzoku no Kenkyu*, Japan, Vol. 9, July 1932, pages 292-294. It was experimentally shown that by the transformation of α-iron $\rightarrow$ γ Fe a deviation of about 20° from the case found by Kurdjumow & Sachs may occur and the degree of the rotation of the lattice as a whole is different in each case and also that when Fe is transformed from α into γ modification the lattice of the latter has, when cooled, a tendency to return back to that of the former in its initial orientation. KT (5b)

Diffusion and Decomposition in Solid Solutions. (Zur Diffusion und Entmischung in Mischkristallen.) A. Smekal. *Zeitschrift für Metallkunde*, Vol. 24, June 1932, pages 121-124. Theoretical considerations on this subject by Hanemann and Schröder (*Zeitschrift für Metallkunde*, Vol. 23, 1931, pages 269, 297) are criticized and amplified. The assumption of "perfusion directions" by them is discredited; the difference in precipitation velocities in substitutional and interstitial solid solutions is explained simply by differences in diffusion velocities. The volume change accompanying precipitation is held to produce strains along certain lattice planes (slip, shear, cleavage, fracture) which initiate precipitation and thus lead to the formation of lamellar precipitate forms. It is suggested that such strains may be detected by the reflection of polarized light. See next abstract. RFM (5b)

Addendum to article by A. Smekal entitled "Diffusion and Decomposition in Solid Solutions." (Kurzer Beitrag zu der vorstehenden Arbeit von A. Smekal "Zur Diffusion und Entmischung in Mischkristallen.") M. v. Schwarz. *Zeitschrift für Metallkunde*, Vol. 24, July 1932, pages 124-126. The presence of internal strains induced by precipitation have been demonstrated by the reflection of polarized light (cf. M.v. Schwarz. *Zeitschrift für Metallkunde*, Vol. 24, 1932, page 97) from the polished and etched surfaces of Cu-Si alloys. Photomicrographs are given (4 in color) showing that an alloy with 0.85% Si, which does not form a precipitate on cooling, gives no indication of internal strain (uniform color in each grain under the polarizing microscope); that an alloy with 3.5% Cu precipitating β crystals on cooling shows color variations in the neighborhood of precipitated β crystals, indicating a strain accompanying precipitation in the supersaturated matrix. The indications of internal strain are greater in an alloy with 4.6% Si. Strains introduced by polishing are confusing and very deep etching to remove the polishing film produces etch pits and leads to disturbing etchpit reflections; polishing must be very light so that a weak etch will remove the polishing film. RFM (5b)

On the X-Ray Determination of Stresses in Welds. John T. Norton. *Journal American Welding Society*, Vol. 11, Sept. 1932, pages 5-7. Paper presented at the Fall Meeting of the American Welding Society in Buffalo, Oct. 4, 1932. An explanation of the X-ray diffraction method of determining grain size, grain orientation and presence of internal stresses in metals. Photograms of weld metal having deformed grains show pronounced asterism. It is suggested that this method may be used advantageously in the investigation of physical properties of weld metal. TEJ (5b)

Stresses in Technical Work Pieces and Its Detection by X-Rays. (Spannungen in technischen Werkstücken und ihr röntgenographischer Nachweis.) Fritz Regler. *Zeitschrift des Österreichischen Ingenieur-und Architektenvereins*, Vol. 84, Aug. 26, 1932, pages 171-174. The so-called cone-reflection method developed by the author for the determination of internal stresses is described. The method offers a considerable experimental simplification over other methods including that recently described by Wever & Möller. (*Metals & Alloys*, Vol. 3, Aug. 1932, page MA 240). In straight C steels a measuring accuracy of $\pm$ .1 kg./mm.^{2} could be attained up to the yield point. The method was devised on the basis of the assumption that cold working and quenching bring about twists of the space lattice and bending slip, so that these 2 occurrences can be used for quantitative stress measurement. It is suitable for any type of steel and seems to be particularly adaptable to testing stresses in bridges, steel constructions, gas bottles, etc. GN (5b)

Technical X-Ray Photographs and their Evaluation. (Technische Röntgenbilder und ihre Auswertung.) W. Grimm & F. Wulff. *Autogene Metallbearbeitung*, Vol. 25, July 15, 1932, pages 217-221; Aug. 1, 1932, pages 232-237. The differences in the picture taken on a screen or on a photographic film are pointed out and the determination and evaluation of defects is explained in great detail and by means of many photographs. The arrangement and proper use of the apparatus is described and the causes of failure discussed. The composition of a substance is of great importance for the time of exposure as the alloying materials for steels all have a higher atomic weight. The higher the atomic weight the greater the absorption of X-rays, and the longer the time of exposure necessary. A photograph shows the blackening of the plate for Al, cast Fe, steel and Cu under the same conditions of radiation. Ha (5b)

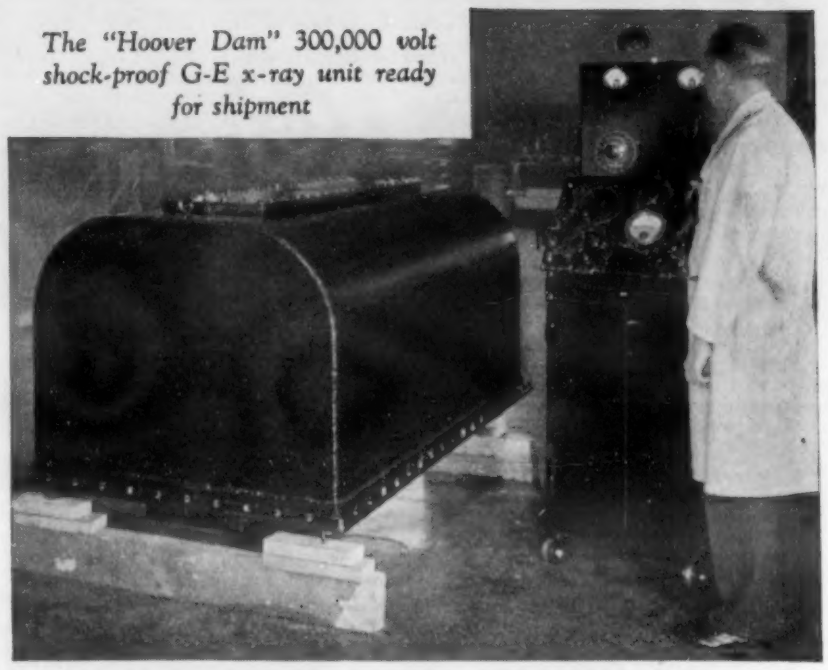
The Ag-Cu-Zn System. (Das System Silber-Kupfer-Zink.) M. Kleinert. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 160, May 1932, pages 15-33. The paper opens with a discussion on the binary diagrams Ag-Zn and Cu-Zn. The constitutional system Ag-Cu was discussed in a previous publication of the author on the Ag-Cu-Mn system (*Zeitschrift für physikalische Chemie*, Abt. A, Vol. 156, Oct. 1931, pages 291-303.) All melts of the ternary Ag-Cu-Zn system, which was studied metallographically, are miscible and in the solid state crystallographic phases only occur which are already known from the binary systems. Corresponding to the striking analogy between the binary systems Ag-Zn and Cu-Zn, formation of complete solid solutions of the corresponding types of crystals (β, γ, ϵ) takes place so that in the ternary system, the analogous couples become one kind of crystals from a phase-theoretical viewpoint. The Zn bearing Ag crystals saturated with Cu, are subject to age-hardening. With regard to the Zn corner, the Zn solid solution η, holds about 4% Cu and 3% Ag in solid solution. At higher Cu and Ag concentrations, the ϵ phase appears. Both γ phases of the Cu-Zn and Ag-Zn diagram form a continuous series of solid solutions. The δ phase, only stable at elevated temperatures, is enclosed by the γ and ϵ field. Regarding the 2 corresponding β crystals, a complete analogy of the space lattice was ascertained by X-rays as well as the occurrence of an intermetallic compound at about 50 atomic %. The micro examinations confirmed the isomorphy of the β phases. The β' crystals show traces of a eutectoid decomposition, as if both phases β'-Cu-Zn and β'-Ag-Zn are separately originated from the β crystals and form a eutectoid mixture. The extent and equilibria of the α solid solution (α-Cu and α-Ag solid solution) among one another and with the β and β' phases are investigated only roughly. An addition of Zn to the Ag Cu phase does not result in a complete mutual solid solution formation unless the saturation of both α crystals with Zn is attained. Two different α phases occur. Since the saturation limit of the Ag crystals with Cu drops with falling temperatures, age-hardening tests were made. The publication concludes with a detailed critical discussion of a previous investigation of Ueno on the Ag-Cu-Zn system (*Memoirs College of Science, Kyoto Imperial University*, Vol. 12, No. 6, 1929) which was laid out on the basis of thermal analyses. EF (5b)

Note on Article "Diffusion and Decomposition in Solid Solutions." (Zuschrift Zur Diffusion und Entmischung in Mischkristallen.) H. HANEMANN. *Zeitschrift für Metallkunde*, Vol. 24, July 1932, pages 164-165. Takes issue with article by A. Smekal. Contains reply by Smekal. RFM (5b)

The Deformation of Ternary Magnesium Solid Solution Crystals. (Über die Dehnung ternärer Magnesium-Mischkristalle.) E. SCHMID & G. SIEBEL. *Metallwirtschaft*, Vol. 11, Oct. 21, 1932, pages 577-579. The deformation under tensile stress of single crystals of 2.8% Al, 0.9% Zn, balance Mg and 5.6% Al, 1.0% Zn, balance Mg, was determined. The orientation of the crystals was determined by X-rays and angle between the base and the longitudinal direction varied between about 10° and 61°. The stress-strain curves are shown. These ternary alloys have a distinct initial slip strength of the base plane corresponding to the yield point. The strengthening of these alloys in comparison with pure Mg is equal to the sum of strengthening of the 2 binary alloys of equal alloy content. The stress-strain curves for the ternary alloys are somewhat flatter than for the corresponding binary alloys. The relation between maximum stress, total elongation and Al content of binary Al-Mg alloys is shown graphically. The 2.8% Al ternary alloy does not vary much from the corresponding binary alloy, but higher values are obtained for the 5.6% Al ternary alloy. CEM (5b)

The Tungsten Cobalt System. (Über das System Wolfram-Kobalt.) CURT AGTE, KARL BECKER & FRHR. v. GÖLER. *Metallwirtschaft*, Vol. 11, Aug. 12, 1932, pages 447-450. Samples of W-Co alloys were prepared from 99.99% W and 98% Co by pressing the mixed powders and sintering them in H_2 atmosphere, raising the sintering temperature 50° at a time. The temperatures at which the surface melted were used in plotting the solidus curve. The samples were then quenched in water and examined magnetically, microscopically and by X-rays. The solidus curve does not show any point corresponding to a compound. By the other methods it was determined that Co is soluble up to about 10 atomic % in W, producing a considerable drop in melting point but no change in the lattice. W is soluble in Co up to 8 atomic % Between these 2 phases only one other intermediate crystal form exists, which has a variable composition of 50 to 62.5 atomic % Co. With increasing Co content the average lattice constant of this crystal form increases by .4%. On the W side it is non-magnetic, but becomes slightly magnetic with increasing Co content. Between 10 and 50 atomic % Co the alloys consist of a heterogeneous mixture of solid solution of Co in W and the W-Co crystal form. Between 62.5 and 90 atomic % they consist of a mixture of solid solution of W in Co and W-Co crystal form. CEM (5b)

Material Testing and X-Ray Stereo-Cinematography. (Die Materialprüfung und die Roentgen-Stereokinematographie.) G. KOEGEL. *Angewandte Chemie*, Vol. 45, Jan. 9, 1932, pages 43-44. The possibilities and requirements of stereoscopic projections of the metallic structures on a luminescent screen are discussed and several apparata for this purpose reviewed. Exact measurements can be made by these pictures only with certain precautions. Ha (5b)



On the Regler Calibration Method for Precision Determinations of Space Lattice Dimensions and the Authors' Method. (Über die Reglersche Eichungsmethode zur Präzisionsbestimmung von Gitterdimensionen und die unsrige.) N. H. KOLKMEIJER & A. L. TH. MOESVELD. *Physikalische Zeitschrift*, Vol. 33, Mar. 15, 1932, pages 265-269. The calibration method for precision determinations of space lattice dimensions of powder photographs, previously published by Regler (*Physikalische Zeitschrift*, Vol. 32, Sept. 1931, pages 680-687) is compared with the authors' calculations independently published at the same time. (*Zeitschrift für Kristallographie*, Vol. 80, Sept. 1931, page 63-90.) Special consideration is paid to the formulae concerning the corrections for the thickness of the sample. The agreement of both methods of calculation is very satisfactory for a certain choice of the anti-cathode focus. EF (5b)

Lattice Parameters of Solid Solutions of Silicon in Copper. H. F. KAISER & C. S. BARRETT. *Physical Review*, Vol. 37, June 1931, page 1697. A brief review of a paper presented before the American Physical Society. WAT (5b)

Radium in Engineering Inspection. V. E. PULLIN. *Engineering*, Vol. 153, May 6, 1932, pages 492-494. Compares use of radium and X-rays in the examination of materials. In examining castings and forgings up to 3" of steel, X-rays are more satisfactory than radium because the exposure time is less and finer detail can be seen. Radium can be used to advantage for detecting big cracks, blow-holes and corrosion cavities in large structures. Radium can be used in places where access is impossible by an X-ray tube. Neither method is practical for routine testing. LFM (5b)

The Iron-Mercury System and the Solubility of Nickel in Mercury. (Ueber das System Eisen-Quecksilber und über die Löslichkeit von Nickel in Quecksilber.) EVA PALMÄER. *Zeitschrift für Elektrochemie*, Vol. 38, Feb. 1932, pages 70-76. The solubility of Fe in Hg was determined in the case of amalgamated Fe wire, and was found to be about 0.00007% by weight, and to be practically constant between 20° and 211° C. The crystals that were deposited out of the Hg on the electrolytic Fe (the so-called iron-amalgam) were found, when separated, to consist, not of a definite compound of Fe and Hg, but of pure Fe that had been suspended in the Hg. The solubility of Ni in Hg was determined by stirring Hg with Ni wire, and was found to be 0.00014% by weight at 20° C. Ha (5b)

The Crystal Structure of AuCd. A. ÖLANDER. *Zeitschrift für Kristallographie*, Vol. 83, July 1932, pages 145-148. (English) Investigation of the intermediate phase (β phase) in the binary system CdAu around 50 atomic %, gave the following dimensions of the unit cell: a = 3.144 A. U., b = 4.851 A. U., c = 4.745 A. U. The specific weight of the alloy was found to be 14.5, hence there are 4 atoms to the elementary body. The probable space group is V_h^5. The alloy has the same structure as the corresponding phases in the AuZn and CuZn systems when the temperature is above 267° C., whereas below this point the lattice will be "wrinkled" in a very remarkable way. EF (5b)

The "Hoover Dam" 300,000 volt shock-proof G-E x-ray unit ready for shipment

G-E X-Ray Equipment to radiograph penstocks at Hoover Dam

WHEN Babcock & Wilcox were awarded the penstock contract for the colossal Hoover Dam project, they found themselves faced with the mammoth task of checking every inch of all fusion welds by radiographic inspection. *These fusion welds totaled more than 75 miles in length!*

Based on their experience with G-E x-ray equipment in their Barberton plant, Babcock & Wilcox turned to the General Electric X-Ray Corporation for apparatus which would fulfill these stipulations. As a result, they have been equipped with the 300,000 volt oil-immersed x-ray unit shown here.

This equipment, the most powerful shock-proof industrial x-ray apparatus in use at the present time, has its complete high tension system—transformers, condensers, Kenotrons and x-ray tube—completely immersed in oil and sealed within a compact tank or "head." This head will be so mounted that the x-rays can be quickly directed at any angle required. There is no possibility of accidental high tension shock, as the only external wiring is at low tension, connecting the head, control stand, and power source.

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Notched Bar Testing (Kerbschlagprobe). E. STARCK. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 412-414. Brief résumé of the various bar sizes and notch types. HWG (6)

The Testing of Castings. WALTER ROSENHAIN. *Journal Institute of Metals,* Vol. 48, 1932, pages 273-285; *Engineering,* Vol. 133, Mar. 25, 1932, pages 383-385; *Foundry Trade Journal,* Vol. 46, Mar. 10, 1932, pages 154-156; *Heat Treating & Forging,* Vol. 18, June 1932, pages 362-364; July 1932, pages 420-422. See *Metals & Alloys,* Vol. 3, Nov. 1932, page MA 322. OWE + LFM + MS (6)

Loading Tests with New Type Welded Beams. (Belastungsversuche mit neuartigen geschweissten Trägern.) RUDOLF ULBRICHT. *Elektroschweissung,* Vol. 3, Jan. 1932, pages 12-13. As contrasted with former welded sheet beams half T-irons are used. This offers the advantage in that the welded seams are located closer to the neutral axis. The new beam proved successful in a number of cases. The results of loading tests are reported. GN (6)

A New Type of Dynamic Balancing Machine. E. L. THEARLE. *Transactions American Society of Mechanical Engineers,* Vol. 54, June 15, 1932, Applied Mechanics, pages 131-141. In this method of determining the planes of correction where balancing weights have to be added or removed, the rotating body to be balanced is suspended rigidly on one end, the other supported by a spring. The theory of the method is developed; the machine employs an automatic compensating device so that even an unskilled operator can obtain accurate readings of amount and position of unbalance. The operation of the machine is described. Ha (6)

Photoelastic Study of Shearing Stresses in Keys and Keyways. A. G. SOLAKIAN & G. B. KARELITZ. *Transactions American Society of Mechanical Engineers,* Vol. 54, June 15, 1932, *Applied Mechanics,* pages 97-123. The technique of photoelastic determination of stresses in structural members using bakelite as the transparent medium is described. The mechanical properties of bakelite and the process of annealing it for the removal of internal stresses are explained. A great number of photographs are reproduced showing that rounding the corners and corresponding chamfering of the key reduces the stresses. Ha (6)

The Notched-bar Impact Test as an Acceptance Test. (L'essai de résilience comme essai de réception.) A. STECCANELLA. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 379-387. The tensile and impact specifications for various grades of steel used by the Italian railways, and the usual range of impact figures given by the material delivered are shown in tables and diagrams. In 16 of these grades the results are based on tests of 1000 to 15000 specimens. Impact tests are regularly made on all steel that is subjected to the tensile test. A Mesnager notch is used. HWG (6)

Elastic and Inelastic Behavior in Spring Materials. M. F. SAYRE. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Applied Mechanics, pages 99-105. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 143. Ha (6)

Rockwell Testing. (Die Rockwellprüfung mit Verspannung.) GEORG REICHERTER. *Die Werkzeugmaschine,* Vol. 36, Sept. 30, 1932, pages 333-336. After surveying Brinell and Rockwell tests and their relations, advantages and disadvantages of both of the tests are considered, the Rockwell test being distinguished by the possibility of testing the hardest pieces and avoidance of measuring the indentation. Special fixtures are described to avoid displacement of intricate pieces on the testing table during the test. Illustrations show such fixtures for testing tips of tool steels, conical shafts and bevel gears. In using these fixtures a modified Rockwell tester must be applied. GN (6)

Impact Tests—Standard Test Pieces. (Kerbschlagproben—Normenprobe.) M. SCHMIDT. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 365-371. Discussion of the factors of size and shape of specimen. The author prefers the V notch. HWG (6)

Wear of Metals. SAMUEL J. ROSENBERG & HARRY K. HERSCHMAN. *Metals & Alloys,* Vol. 2, Feb. 1931, pages 52-56. The authors analyze different types of wear and describe a number of wear testing machines. Laboratory tests where conditions can be accurately known and quickly made are essential for development of materials. The wide difference in the effect of different types of service on a given material necessitate correlation with service tests which is beset with difficulties. In discussion of the interpretation of wear test results 7 factors due to the metal and 8 due to the service are tabulated. Conditions of service such as a tire chain are discussed where some other factor as resistance to shock must be considered along with a wear test result. Attempts to relate wear resistance with other mechanical properties has been unsatisfactory, though it is generally true that hard materials resist wear better than soft materials there are numerous instances of the reverse. The mechanism of abrasion is discussed and it is shown that wear in a Brinell wear testing machine took place by tearing of particles of the grains away from the surface accompanied by severe local straining. 21 references. WLC (6)

Meaning of the Notched-bar Impact Test for Investigation and for Acceptance Test Purposes. R. H. GREAVES. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 372-378. Discussion of the transition range in a plot of energy absorbed versus temperature of test, as affected by dimensions of the bar, and other factors. A high impact figure does not insure that the material may not show brittle behavior at a slightly lower test temperature. Demanding a good impact figure in a test at the temperature of service tends to eliminate steels of the class in which adventitious failures are likely to occur. In the experience of Woolwich Arsenal, much of the material that has actually failed in service by cracking, gives poor notched-bar tests, and the concordance is too high to be accidental. HWG (6)

The Standardization of the Notch-Impact Test. (Zur Normung des Kerbschlagversuches.) M. MOSER. *Zeitschrift Verein deutscher Ingenieure,* Vol. 76, Mar. 12, 1932, pages 257-261. The author points to the present impossibility of a comparison of the results of notch-impact tests, as is possible with tensile strength. Not only in different countries, but also in the same country are the tests made in a different manner, and so it is suggested that a standard test be developed which is suitable by the shape of the test piece and kind of notch, to distinguish as correctly as possible between different steels and their properties at room temperature. Additional tests which might be necessary should be restricted to a minimum. Several samples are illustrated which are all of smaller size than the test piece for the Charpy test. Ha (6)

The Notched Bar Impact Test in Germany. (Der Stand der Kerbschlagprobenfrage in Deutschland.) M. MOSER. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 342-355. The impact test has value in classifying materials even though the quantitative figure is not used in design. The shift of the impact curve with temperature and with the aging of an alterable steel is illustrated. The standard German Charpy specimen is 10 mm. square, 55 mm. long (40 mm. between supports, with a round notch 2 mm. (0.078") diameter, 3 mm. (0.118") deep). For very tough materials, a 45° V notch with 0.5 mm. radius at the base, and of the same depth may be used, but the round notch is preferred for general use. Abstracts of, and references to, 33 papers. HWG (6)

Plasticity of Copper-zinc Alloys at Elevated Temperature. ALAN MORRIS. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 336-352. Includes discussion. See *Metals & Alloys,* Vol. 2, June 1931, page 112. (6)

Full-Load Calibration of a 600,000-lb. Testing Machine. H. F. MOORE, J. C. OTHUS & G. N. KROUSE. *Transactions, American Society for Testing Materials,* Vol. 32, Pt. 2, 1932, pages 778-782. The paper describes the calibration of a screw-power, balance-beam testing machine of 600,000-lb. capacity. The calibration was made by the use of two 10,000-lb. standard weights and an elastic bar fitted with a delicate strainometer. The elastic bar was used merely as a transfer instrument, and it was not necessary to evaluate its elastic constants. All that was necessary was to have a strainometer sufficiently sensitive that load on the bar could be reproduced a few moments later with a high degree of accuracy. After 27 years of rather severe service the testing machine was found to still have a high degree of accuracy and sensitivity. VVK (6)

The Determination of the Depth of the Case of Case-Hardened Pieces. (Ueber die Bestimmung der Einsatztiefe bei im Einsatz gehärteten Werkstücken.) WALTER MELLE. *Werkstattstechnik,* Vol. 26, Jan. 15, 1932, pages 21-24. The thickness of the hardened case of a case-hardened piece can be determined by the Rockwell hardness test by measuring the hardness with 2 different weights when making the test. A diagram shows the relation giving depth as ordinate against hardness as abscissa. Ha (6)

Discussion on Impact Testing. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 388-405, 415-420. The representatives of the various countries agreed that it would be fine to have an international standard impact bar, but each one wanted this to have the notch with which his own country's main stock of data had been obtained. The bulk of the evidence was in favor of a V notch on the ground that it is more discriminating than the round notch, but the German and British practice in depth of notch and root radius is so different that neither one is likely to give way. For the less tough materials, the Mesnager type of notch is required, but here again the practice as to radius and depth varies. All the discussion referred to Charpy type of bar which is apparently far more popular at present in all the countries represented than is the Izod. HWG (6)

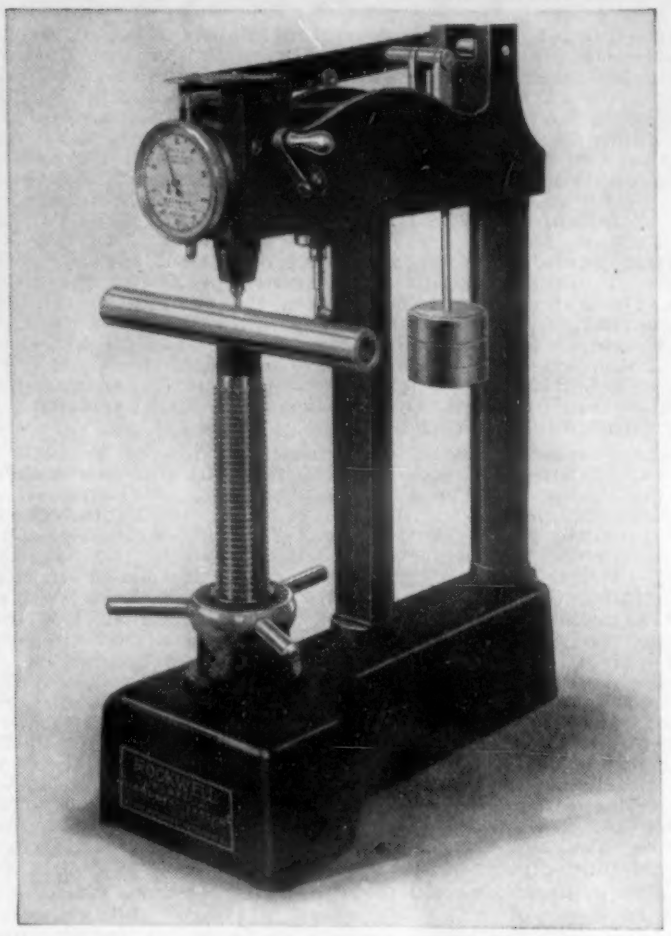
Testing Sheets for Deep-Drawing Qualities. *Iron & Coal Trades Review,* Vol. 124, May 20, 1932, page 837. From a report by F. Eisenholb, *Stahl und Eisen,* Vol. 52, Apr. 14, 1932. See *Metals & Alloys,* Vol. 3, Nov. 1932, page MA 322. Ha (6)

The Damping Capacity of Copper, Zinc and Its Alloys at Dynamic Tension-Compression Stresses. (Die Dämpfungsfähigkeit von Kupfer, Zink und ihren Legierungen bei dynamischer Zug-Druck Beanspruchung.) R. GÖTZELT. *Forschung, Zeitschrift Technische Mechanik und Thermodynamik,* Vol. 3, Sept./Oct. 1932, pages 241-246. The experiments were carried on in the apparatus described by Voigt in *Zeitschrift für technische Physik,* Vol. 9, 1928, page 321. For measuring the damping capacity of relatively plastic metals such as Cu and its alloys proper dimensioning of the test bars and special precautions in clamping the bars in the grips of the machine are necessary. For Cu, brass and bronze certain damping ranges were found, i.e. a decrease of initial damping, an increase of damping capacity with increasing load and constant damping capacity at every load stage below the fatigue limit. Above this limit damping did not attain constant values. The constant damping decrements obtained with the initial load were practically always the lowest; they were not altered after a longer interruption of the load. As contrasted with this result the constant curves taken at higher load stages showed a considerably lower course after a 24 hr. rest; a few of the values were even lower than the lowest values obtained with the initial load stage. After short loading, however, the curves returned to the original stable location. The damping values for various brands of commercial brass show but slight differences. The damping of the alloys is appreciably smaller than that of its 2 main components. Damping of high grade alloys shows characteristic deviations from commercial brands. At equal loads special Cu shows a considerably higher damping than commercial Cu. For Zn the damping capacity does not increase in increasing the load. Slight injuries of the bar surface do not affect damping properties. In testing the damping capacity of brass between −120° and +400° C., a maximum of damping was found at −50° C. and a minimum at +270° C. 13 references. GN (6)

Testing for Hardness. (Härteprüfung.) B. Buxbaum. *Zeitschrift für Instrumentenkunde,* Vol. 58, Feb. 1932, pages 87-88. The writer critically discusses the conception "hardness" and the commercial hardness testing machines. The greatest reliability is ascribed to the Rockwell Machine, but 6 main sources of error are pointed out and their degree of error is estimated. Due to an additive effect, divergencies of 5 Rockwell units may occur. Then the author deals with his improved testing method based on filing with a tool that incorporates a large hardness scale. EF (6) 1

The Strength of β′ Brass. (Über die Festigkeitseigenschaften von β′-Messing.) U. Dehlinger & F. Mendl. *Metallwirtschaft,* Vol. 11, July 29, 1932, page 424. The β to β′ transformation in brass, which is accompanied by an increase in elongation and decrease in tensile strength, requires a longer annealing period than is usually used in industry. 2 samples of brass containing 51.8% and 52% Cu were pressed at 600° C. and annealed at 430° C. for 24 hours. No difference in structure could be determined by microscopical examination. Annealing at 600° C. for 1 hour produced recrystallization, but subsequent annealing at 430° C. for 24 hours produced no further change. Results of the tensile tests are given. 4 references. CEM (6) 2

On the Significance of the Yield Point for Non-ferrous Metals. (Über die Bedeutung der Streckgrenze bei Nicht-Eisen- Metallen.) Bosshardt. *Schweizerische Technische Zeitschrift,* Vol. 29, Aug. 25, 1932, pages 521-523. It is shown that the yield point of non-ferrous metals, defined as the stress at which the permanent elongation amounts to .2% is no satisfactory yardstick for their mechanical properties. After dealing with the relations between yield point and cold working as well as tensile strength and cold working the author points out that the mechanical properties of non-ferrous metals are sufficiently characterized by tensile strength, elongation at fracture and hardness. GN (6) 3



Measurement of Angular Strains During the Twisting of Cylindrical Specimens. C. E. Larard. *Engineering,* Vol. 133, Apr. 8, 1932, pages 417-418. In studying the behavior of ductile material during twisting to destruction, it is necessary to have an accurate instrument to measure the angles of twist corresponding to the increasing twisting moments. 2 such instruments are described (1) a high-precision torsionmeter for measuring very small increments of angular strain through the so-called elastic period and beyond the normal yield point, and (2) a handy laboratory torsionmeter for measuring angles of torsion through both elastic and plastic stages. The former is used for measuring the large plastic or viscous strains up to the maximum torque for destruction; the large instrument is used for moderately large and very large torsion specimens up to and over 3″ diameter and the laboratory instrument for the testing of small and moderate diameter specimens. LFM (6) 4 5

Kinematography in Photoelasticity. Max M. Frocht. *Transactions American Society of Mechanical Engineers,* Vol. 54, June 15, 1932, Applied Mechanics, pages 83-96. One of several methods of stress analysis in metals is photoelasticity. The author describes an arrangement which used cinematographic pictures of stress distribution taken in monochromatic light. A great number of the moving pictures are reproduced. They show a variety of stress-distribution patterns and their formations. Stress concentration can spring from various sources such as holes, notches, grooves, scratches, etc. A layer of rubber, Pb or wood has been found to eliminate stress concentration due to a die. When sources are many and close they can become mutually destructive. Applications for practical purposes are illustrated. Ha (6) 6

Special Methods of Testing Aircraft Materials. David M. Warner. *Transactions American Society of Mechanical Engineers,* Vol. 4, July-Sept. 1932, Aeronautical Engineering, pages 141-149. The testing of welded and riveted joints, axles, wheels and brakes, struts, beams, etc., as applied at the Wright Field for airplanes is described in detail. It is recommended to make the tests on aircraft engine materials above the temperature ranges to which they are subject in service. Service conditions should be simulated as nearly as possible. Testing apparatus is described and charts reproduced. Ha (6) 7

Permeability of Sheet Steel. G. Waters. *Electrical Review,* Vol. 110, Apr. 29, 1932, page 628. Describes method of testing and includes curves showing results of tests on 4 different makes of steel. Analyses of the specimens are not given. MS (6) 8

Plastic Flow at the Compression Test. (Das Fliessen beim Druckversuch.) Hans Waschek. Dr. Ing. Thesis, Technische Hochsche, Breslau, 1932, 94 pages. The paper first discusses the literature on the subject with special reference to plastic flow in a most comprehensive manner. Tests were undertaken to simplify and facilitate the method for measuring the crystal deformation as previously described by Tafel & Scholz. (See *Metals & Alloys,* Vol. 1, July 1930, page 639). Cylindrical samples of .05 C steel (Krupp WW), 28 mm. high, 24 mm. diam., tensile strength 29 kg./mm.², elongation 38.7%, reduction of area 79.6%, were normalized for 1 hr. at 900° C. and 930° respectively and then upset in a 500 ton press with a maximum velocity of 170 kg./sec. = .35 kg./mm.². Samples were upset by 20%, 35%, 50%, and 70%. The control measuring method for plastic deformation which was combined with the calculation in the above mentioned paper was separated from it and modified so that it can be used independent of the calculation. The previous equations on calculating the course of plastic deformation were also modified for compressive tests. 2 numerical examples illustrate the calculation. With the aid of this modified method the crystal deformation was investigated for the stress distribution. The grain sizes were measured in various cross-sections of all upsetting stages. On the basis of the results various hypotheses on plastic flow are considered; that by Tafel was substantially verified. In compressive tests plastic deformation is a deformation of crystals as well as a displacement in regard to their mutual location, as in the case of tensile tests. These fundamental occurrences were also observed in the compressive test, the results, however were not sufficient to evaluate them quantitatively. 48 references. GN (6) 9 10

Lightly Carburized Work can be tested for hardness

Cyanide hardened steel parts, and pack hardened parts that are carburized at low temperatures or for short time, present a problem in hardness testing much the same as does nitrided steel.

Manifestly any indentation hardness test must, on such work, be based on minute indentation. Manifestly also, any hardness measurement based on a minute impression involves great sensitivity and precision of depth measurement if the determined values are to be reliable and the hardness inspection useful.

The *ROCKWELL SUPERFICIAL Hardness Tester* was designed for just that class of work and it is doing it and doing it well.

On the Effect of Notches on the Strength of Structural Parts. (Ueber den Einfluss von Kerben auf die Festigkeit von Konstruktionsteilen.) EUGEN ARMBRUSTER. *Zeitschrift des bayerischen Revisionsvereins,* Vol. 36, Sept. 30, 1932, pages 199-205.
Calculation of the stress distribution on notches is not yet sufficiently cleared up to be of practical value. Suitability, applicability and disadvantages of the various methods for stress measurement (extension measurements with fine measuring instruments, photo-elastic method, measurements on rubber model bodies) are discussed. Important factors for the notch effect at dynamic stresses and its numerical effect on the fatigue limit are considered as, for instance, form of notch, method of processing notches, surface condition of notch, etc. The following rules are given for avoiding fatigue failures. (1) Precise machining of all highly strained parts, (2) avoidance of subsequent injuries, (3) increase of tensile strength by surface pressing, (4) avoiding of sharp changes in cross-section, (5) rounding of edges by chamfering, and subsequent pressing of the chamfer in order to work harden the highly stressed points, (6) cross bore holes for lubrication are to be rounded off on the surface, subsequent pressing of the edges is advantageous, (7) the direction of lubricating grooves should, if possible, coincide with a direction of principal stress. GN (6)

Impact-Tensile Tests with Sample Rods of Welded Steel Sheets. (Schlagzugversuche mit Stäben aus geschweissten Stahlblechen.) *Zwanglose Mitteilungen des Fachausschusses für Schweisstechnik,* No. 20, Mar. 1932, pages 4-7.
Tests were made to determine whether the material in welded seams is stronger or less capable of deformation than the parent material, to determine if the fracture is brittle or if the deformation energy is absorbed by the material as well as by the weld. The impact test was chosen because the impact acts not only, as in the impact-bending test, on the welded seam but on the entire welded joint. The preparation of the samples and the results are described. It was found that a brittle fracture under the given conditions does not occur; on the contrary, the weld which has less strength than the sheet but a greater deformability is inferior in its behavior under impact stress. A good weld should, therefore, have at least the same strength as the parent material in order to utilize the deformability of the sheet as much as possible; the weld must possess a certain capacity for deformation. Whether the same conditions hold good for oscillating endurance loads has not yet been ascertained. Ha (6)

The Dependence of the Permeability of Iron Wires on the Field in Case of High Frequency. (Die Abhängigkeit der Permeabilität von Eisendrähten vom Felde bei Hochfrequenz.) M. WIEN. *Physikalische Zeitschrift,* Vol. 33, Feb. 15, 1932, pages 173-175.
Tests were made on 0.5 mm. Fe wires at low frequencies and at high frequencies of 31, 96, 700 and 3400 m. wave length. An increase of wave length with cycles was noticed at all high frequency wave lengths. According to Ewing's conception the results can be interpreted as follows: the initial permeability corresponds to the completely elastic movements of the elementary magnets. Then the permeability becomes dependent on the frequency and a phase loss occurs after the elementary magnets pass the elasticity limit and friction occurs. This part is more extended in the high frequency field. EF (6)

Contribution on the Critical Valuation of the Bending Test on Welded Samples. (Beitrag zur kritischen Wertung des Biegeversuchs an geschweissten Proben.) K. JURCZYK. *Elektroschweissung,* Vol. 3, Aug. 1932, pages 154-155.
Angle of bending is not the proper measure for the elasticity of welded joints. The effect of plate thickness, curvature diameter and distance of bending rolls on the results of bending tests are discussed. A new bending device is described which avoids the faults of former constructions. GN (6)

Tests on Cast Iron—a Consideration of Test Results Obtained in Czechoslovakia. M. F. PISEK. *International Association for Testing Materials, Zurich Meeting,* 1931, Vol. 1, 1932, pages 56-74. (In English.)
Recounts cooperative work of the Czechoslovakian Standards Association comparing tensile, transverse, hardness and shear tests on 22 classes of iron. Frequency curves are shown. Tensile specimens of the American standard form were prone to fracture away from the test section. A gradual taper with only a short cylindrical section is preferred by the author. The shear test was found to show the smallest divergence from proportionality to tensile tests, being more uniform than transverse tests. HWG (6)

The Strength of Thin Plates in Compression. TH. VON KARMAN, E. E. SECHLER & L. H. DONNELL. *Transactions American Society of Mechanical Engineers,* Vol. 54, Jan. 30, 1932, Applied Mechanics, pages 53-57.
In aeronautical structures, thin metal sheets are often used beyond the stability limits and the load which can be carried by the structure is determined by the ultimate strength in compression. Recent experiments by the Bureau of Standards have shown the ultimate load to be independent of width and length of the plate and approximately proportional to the square of the thickness. The theoretical analysis shows the ultimate strength of a plate to be proportional to the square roots of the modulus of elasticity and the yield point of the material and to the square of the thickness. Tests agree well with the theory. Ha (6)

Experimental Researches on the Barkhausen Effect. (Recherches expérimentals sur le phénomène de Barkhausen.) ST. PROCOPIO. *Revue Générale de l' Electricité,* Vol. 31, Feb. 13, 1932, pages 211-213.
Abstract from *Annales scientifiques de l' Université de Jassy,* Vol. 16, Mar. 1931, pages 352-374. Study of influence of intensity of magnetizing of the substance considered and of passage of alternating-current through the substance. Concludes that Barkhausen effect is due to the orientation of the elementary particles and that it is proportional to the variation intensity of magnetization. Passage of an axial alternating-current increases it, this increase depending upon the values of the alternating-current and of the constant magnetic field for which Barkhausen effect is being investigated. Influence of alternating-current on the phenomenon is due to increases in magnetization of the Fe. MS (6)

Fatigue of Metals (6f)

Surface Stresses and Fatigue Fracture of Anti-Friction Bearings. (Oberflächenspannungen und Ermüdungsbruch bei Wälzlagern.) R. MUNDT. *Forschung auf dem Gebiete des Ingenieurwesens,* Vol. 3, May/June 1932, pages 127-134.
The results of running tests on 3 ball bearings are compared with theoretical considerations of Hertz on the conditions of stress at the contact of curved surfaces. It is shown that the influence of surface deformation on the carrying capacity of a bearing is quite different from the expectations based on the calculation of the normal stresses. Similar considerations on roller bearings prove that such bearings are much better fit to take up intermittent loads than ball bearings. Tests on roller bearings show that the tangential stresses are not only constant for various-sized bearings but that, for equal duration, the stresses correspond to those of ball bearings. 15 references. METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Standardization of Chemical Methods of Testing Metallic Coatings. N. A. ISGARISHEV & N. P. EGOROVA. *Tzvetnuie Metallui,* No. 6, June 1931, pages 713-719.
The authors studied the relative merits of various chemical methods for determination of thickness and uniformity of Zn coatings. They recommend the method of Bauer (H_2SO_4 and As_2O_3) for the determination of thickness, and the method of Werulund (acetic acid and H_2O_2) for detection of holes in the Zn coatings. The cupric sulphate method is considered incorrect and is not recommended. BND (8)

The Cathode Sputtering of Beryllium and Aluminum in Helium. P. D. KUECK & A. KEITH BREWER. *Review of Scientific Instruments,* Vol. 3, Aug. 1932, pages 427-429.
For the production of the He spectrum, Be proved to be a more suitable cathode material than Al; the arc burns much more quietly, the number of atoms sputtered is 1.5 times greater than for Al. Also the light transmission is far greater for Be. The higher melting point of Be is another factor in its favor (1350° against 658° C.) Ha (8)

Spraying Molten Metal to Combat Corrosion. *Petroleum Engineer,* Vol. 3, Aug. 1932, pages 38-40.
One of the methods now used with success to prevent or reduce the corrosion of refinery equipment consists in spraying molten metal onto the metal surface to be protected. The atomized metal is driven into the pores of the surface receiving it, cools instantly, and becomes a part of it. The surface must first have been cleaned and roughened by sand-blasting. Several coats may be applied if desired, or an under-coating of Zn may be laid on first. Al coating on exhaust ells of gas compressors that had been on trial for 10 weeks appeared to be perfectly tight at the end of that time. EF (8)

The Electric Oxidation of Aluminum with Polarized Alternating Currents up to high Frequencies. (Die elektrische Oxydation des Aluminiums mit polarisierten Wechselströmen bis zu hohen Frequenzen.) F. WOLHR. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Apr.-June 1932, pages 94-98.
A polarized high-frequency current is a current on which a direct current of such value is superimposed that the resulting current has a wave form on one side of the zero-axis only with the zero value on this axis. The effects on and the properties of oxide films produced with such currents were investigated and compared with direct current which was interrupted mechanically and by a Wehnelt interrupter. It was found that the breakdown voltage of the oxide film depends to a great extent on the frequency of the polarized current; it increases from 50 cycles to a maximum at 1000 cycles and then decreases rapidly; the best value was 6000 V for all frequencies but the scattering of the values was much greater than at 1000 cycles. The maximum at 1000 cycles is explained by the anodic gas charge of the base metal and the diffusing of the electrolyte which, at this frequency, seems to go on easiest. Ha (8)

The Electric Oxidation of Aluminum. (Die elektrische Oxydation des Aluminiums.) HANS SCHMITT. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk,* Vol. 4, Apr.-June, 1932, pages 79-94.
The oxide film formed on Al acts as a valve for alternating current and has also a corrosion protective and electrically insulating effect. According to the use the oxide film was formed with the particular purpose in view. A new method was developed by the V.A.W. Lautawerk, Berlin, which produces on Al and Al alloys oxide films which show the protective action in a considerably more pronounced degree as the crystalline structure of the oxide film can be varied so that the range of application is greatly enlarged. The method of producing the oxide films in baths or solutions of definite composition is treated in detail, the properties of the film vary according to whether alternating or direct current was used for the oxidation. The treatment is different for Al parts which are not bent in service, such as plates, sheets, and those which are subject to bending, such as wire, strips, etc. The oxide film consists normally of a pure γ Al oxide which is crystalline but has an extraordinarily fine grain. By a certain treatment this γ oxide can be converted into Al hydroxide (poor in water) and the fineness of the grain can be influenced. The bath consists of a solution of 3-10% oxalic acid with additions of up to 0.1% chromic acid into which the objects are immersed at 15-30° C.; the current density should be 60-300 amp./dm.^{2} at 60-100 volts; both alternating or direct current, or also high-frequency rectified alternating current can be employed. The hardness of this oxide film is very great, and the dielectric strength excellent; the breakdown voltage for a film of about 0.05-0.1 mm. is 2500 volts at ordinary air pressure, decreasing only slightly to about 2200 volts at 100 kg./cm.^{2} pressure. Layers up to 0.8 mm. can be produced but usually 0.05 to 0.1 suffice for practical purposes; temperatures of more than 200° C. damage the films. The melting point of the film is very high; the thermal utilization is therefore limited by the Al itself. Many practical applications, such as insulated wires in transformers for 5000 volts, for refining the surface of castings, etc. are described, and the mechanical properties, hardness, suitability for bending, corrosion-resistance, coloring of surface, etc. are illustrated. 23 references. HEAT TREATMENT (10)

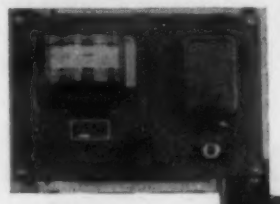
The Heat Treatment and Manufacture of Small Automotive Steel Parts. ERNEST F. DAVIS. *Fuels & Furnaces,* Vol. 9, Dec. 1931, pages 1345-1350. Bolts, screws and studs for automobile construction require about 500,000 tons of steel annually of 3 general types, alloy steels for highly stressed parts, medium C (0.30-0.50 C) to stand medium stresses, and low C open hearth or Bessemer steels for parts of less vital importance. Carburizing to a depth of .010" to .060" is applied to parts subject to wear. The S. A. E. class numbers of the steels most widely used are given, together with the heat treatments and brief descriptions of some automatically controlled apparatus for hardening and drawing. CMB (10)

Testing of a Material for Regeneration of Steel. (Prövning av ett medel för regenerering av stal.) CARL BENEDICKS. *Jernkontorets Annaler,* Vol. 116, July 1932, pages 339-343. A trade compound "ferronovo" was found no more useful than ordinary oil in regenerating overheated steel. HCD (10)

Boeing Airplane Company. J. B. NEALEY. *Heat Treating & Forging,* Vol. 18, July 1932, pages 433-434; *Iron Age,* Vol. 129, Mar. 10, 1932, pages 606-607, 628. Deals particularly with method and equipment for heat treating Al and its alloys. Immersion type of equipment used. Heating medium is a 50-50 solution of KNO_3 and $NaNO_3$ kept at 940°-950° F. Parts are quenched in cold H_2O and washed in hot H_2O. Time of immersion depends upon thickness of parts. Aging of duralumin rivets after treatment until they can be used is temporarily suspended by placing them in a refrigerator cooled by dry ice. Steels of S.A.E. 2330 and 4130 analysis are also treated. MS + VSP (10)

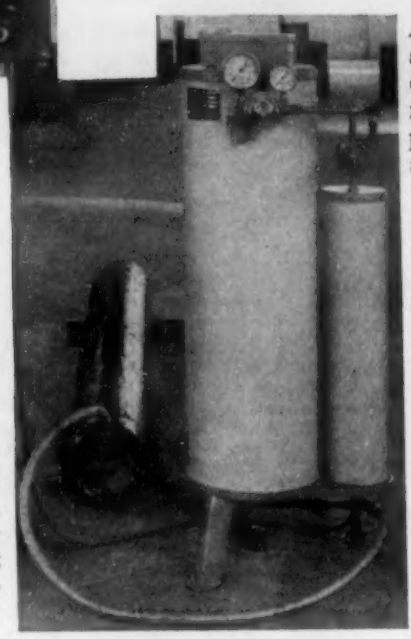
Where Small Tools are Heat-Treated. *American Machinist,* Vol. 76, Apr. 28, 1932, pages 558-559. Heat treating furnaces, quenching baths and pickling methods applied for small tools by the Union Twist Drill Co., Mass., are described. Ha (10)

Heat Treatment of Wheels or Rims in Electric Furnaces. (Vergüten von Radreifen in Elektrischen Oefen.) R. MICULESCU. *Stahl und Eisen,* Vol. 52, July 21, 1932, pages 710-711. In the past 10 years there have been steady increases in railroad locomotive and car weights as well as in running speeds. These have placed greater demands on the wheels and rims. The Roumanian railroads specified material having a minimum tensile strength of 90 kg./mm.^{2} with 8% elongation. The impact test consisted of 3 blows with a 1000 kg. hammer from a height of 10 m. The steel produced in the past could not meet these higher requirements. Cr and Ni steels were prohibitive due to their cost. Basic open-hearth steel, composed of 0.5 to 0.6% C, 0.35% Si, 1 to 0.8% Mn, 0.07% P and S, was used in the investigation. In order to produce a wheel or rim to meet these rigid specifications, heat treatment studies were undertaken. A generator gas-fired furnace was not quite successful for heat treating. Electrical annealing furnaces were successful and for the production required 6 annealing furnaces were employed, 5 small ones and 1 large one. The construction of these furnaces is given. The 5 small furnaces handle 200 small wheels, total weight 58 tons, per 24 hrs., consuming 270 kw-hrs./ton. The large furnace handles 28 large locomotive wheels, total weight 14 tons, per 24 hrs., using 350 kw-hrs./ton. DTR (10)



Obtaining Better Results in Hardening High-Speed Steel. WILLIAM E. SNOW. *Machinery,* Vol. 38, Mar. 1932, pages 486-488; April 1932, pages 590-592. 3 methods of heating for hardening are: the open forge, gas furnace, the electric furnace. The open forge is generally unsatisfactory. Gas furnaces should be no larger than necessary as the larger the furnace the greater chance for cold spots, which must be guarded against. The electric furnace gives more uniform and constant heat than gas and does not have air introduced to the furnace while heating so the steel is not decarburized and is relatively clean. Martensitic structure is desirable in tool steel. This is obtained by very rapid cooling from a temperature above the critical point. Best equipment for hardening consists of a preheating furnace capable of maintaining a temperature of 1800° F.; a hardening furnace of temperature ranges between 2400° and 2450° F.; a tempering furnace to operate between 850° and 1300° F., all furnaces to be pyrometer equipped. A quenching tank of water cooled oil is required. Steel should be quenched from a rising temperature, never allowed to soak at quenching temperature. Steel should be brought to the hardening temperature as rapidly as possible. Working should be done while hot. Heavy hammering while hot increases the density of the steel. Steel for forging should not be heated too abruptly. Single pieces should be taken from the preheating furnace and inserted in the hardening furnace. The piece is to be watched closely. The appearance of the flux on the metal shows the proper quenching time. The "perfect quench" would be instantaneous. This is impossible. Cold water is probably the fastest quenching medium but is too severe, so oil is used as it does not cause cracking as water does. It is important that oil be kept cool. Complete immersion is necessary. In tempering regular high-speed steels the furnace temperature should be kept between 1000° to 1100° F. Steels containing Co should be tempered to 1200° to 1300° F. These temperatures are for heavy duty tools as lathes and planers. Lighter tools do not require such high temperatures. Avoid high temperatures in grinding the tools. If rehardening is necessary the tool should be annealed first. Cyanide may be used for special hardening. Boracic acid gives freedom from decarburization. RHP (10)

Hardening (10a)



Surface Hardening of Metals by Means of the Oxy-Acetylene Torch. (Die Oberflächenhärtung mittels der Azetylen-Sauerstoffflamme.) *Zeitschrift für Schweisstechnik,* Vol. 22, Sept. 1931, pages 208-211. Reports on a lecture of A. E. Shorter before the British Institute of Welding Engineers. The hardness at the surface of C steel (0.25-0.75%), Ni-Cr steels and cast iron used for gears, axles, spindles, brake drums, etc., is raised from 180 Brinell to 500-600 Brinell. Instead of rapid water quenching, air, oil or nitrogen are accordingly applied. Automatic operation instead of manual performance is indispensable. See also "Metal Surface Hardening," *Metals & Alloys,* Vol. 2, May 1931, page 103. EF (10a)

6 **The "Secret" of Copper Hardening. (Das "Geheimnis" der Kupferhärtung.)** RALPH J. SNELLING. *Apparatebau,* Vol. 44, Sept. 16, 1932, pages 127-128. The author deals with the centuries old "secret" of Cu hardening and considers the increase of hardness of Cu owing to (1) oxygen, (2) addition of foreign elements, (3) cold working. Probably all 3 of the methods were known to old copper-smiths and priests. The value of hardness increase of Cu is discussed. GN (10a)

Annealing (10b)

Bright Annealing Furnace Economies. H. HINES. *Metals & Alloys,* Vol. 3, May 1932, pages 113-115. The author describes the economies effected in the handling incident to annealing of mesh bag frames using a conveyor belt type of electric annealing furnace. The furnace atmosphere is controlled to produce a bright annealed article eliminating pickling, drying and handling. The saving in press costs due to better 7 product was sufficient to pay the cost of operating the new furnace so that 100% of the old cost of annealing was saved. WLC (10b)

Theory and Practice of Annealing Steel. (Theorie und Praxis des Stahlglühens.) R. ESCHELBACH. *Werkstattstechnik,* Vol. 26, June 15, 1932, pages 235-240. Descriptive. RFV (10b)

Bright Annealing in the Light of Patents. (Das Blankglühen im Lichte der Patentschriften.) E. FAHRLAENDER. *Deutsche Goldschmiede-Zeitung,* Vol. 35, Sept. 10, 1932, pages 370-371. The paper first deals with the application of various protective 8 gases for bright annealing, as H, N, producer gas, CO_2, O- free air and special gases. Vacuum annealing is then considered. New constructions of bright annealing furnaces, pot annealing as well as electric furnaces, are dealt with. The paper concludes with bright annealing in salt baths. According to recent patents salts free from cyanides are suggested which proved successful. Further improvement of all of the methods as regards refinement and simplicification of the equipment seems advisable. GN (10b)

Case Hardening & Nitrogen Hardening (10c)

9 **Nitriding for Small Production Obtained at Low Expense.** R. R. LAPELLE. *Automotive Industries,* Vol. 66, Mar. 1932, pages 390-391; *Iron Age,* Vol. 129, Apr. 14, 1932, pages 874-875, adv. page 18. A new type of nitriding furnace as installed at the Detroit Commercial Steel Treating Plant is described. This installation marks a long advanced step in the development of nitriding equipment. It is of the type which might be termed semi-continuous in principle because, even on limited production, it secured many of the advantages with respect to cost which may be obtained in continuous equipment. Briefly the furnace consists of a movable furnace chamber 10 mounted upon track wheels and located above a stationary hearth. The latter, which is twice the length of the furnace proper, has mounted upon it 2 nitriding retorts, over either one of which the furnace proper may be placed at the will of the operator. Advantages of the stationary hearth used together with the movable furnace are summarized. VSP + DTR (10c)

New Methods of Hardening Steel. (Neue Wege der Stahlhärtung.) Otto Gassner. *Metallwirtschaft*, Vol. 11, Aug. 19, 1932, pages 464-465. The case-carburizing method for hardening steel has the disadvantages of requiring a long time, due to the time necessary to heat the boxes and carburizing material, uneven heating of the parts resulting in distortion, and high cost. A separate hardening operation is usually required. These disadvantages can be overcome by the use of salt baths consisting principally of cyanides. They result in heat and time saving, and parts free from scale, but require a special furnace installation. In the Durapid process steel parts can be hardened in ordinary furnaces in from a few minutes to 1 hour by dipping them in a paste and heating them in the open furnace to above the upper point and quenching in the usual way. An even case is produced with minimum distortion, no scaling and at a great saving of time and heat. CEM (10c)

Mechanical Surface Treatment. (Mechanische Oberflächenbehandlung.) Lang. *Zeitschrift für Schweisstechnik*, Vol. 21, June 1931, pages 135-136. Attention is called to the nitriding process and to the hardening method developed by the Edelstahlwerke consisting in a heating of the Cr, Mo and Si bearing steels by means of an acetylene torch immediately followed by a rapid quenching. The depth of the case depends on the revolving speed and the C and Cr content of the steel. The hardening effect is based on a transformation of sorbite into austenite and martensite. The following data are given: initial cost of the acetylene equipment = 8,000 R.M. and 14,000 R.M. construction expenses. EF (10c)

Hardening of Alloyed Steels by Nitrogen. (Die Härtung Legierter Stähle durch Stickstoff.) Oskar Meyer & W. Eilender. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, Mar. 26, 1932, pages 317-320. A few recent investigations at the Technische Hochschule at Aachen are reviewed which were carried on to elucidate the behavior of Fe during nitriding. The most important alloying elements of a nitriding steel are Al and Cr as they readily form nitrides. This is true of V, Mo and Ti to a lesser degree. The migration of the N into the Fe goes on according to the diffusion law of Fick, and is determined by the migration of the N atoms through the intermediary lattices. The nitride forming capacity decreases with the addition of metals in the order Al, Ti, V, Cr, Mo; the nitrided steels with these additions are all of similar character. The relations between velocity of diffusion and temperature applied are discussed. The application of high-frequency alternating current seems to result in a shortening of time for the process. 22 references. Ha (10c)

Welding & Cutting (11c)

Welding in the Steel Plant. E. L. Quinn. *Blast Furnace & Steel Plant*, Vol. 20, Apr. 1932, pages 346-358; May 1932, pages 425-427.

Except for omission of sections on welding of non-ferrous metals and surface hardening alloys, this article is the same as that in *Journal American Welding Society*, Vol. 10, June 1931, pages 6-10. MS (11c)

Reduced Cost of Bridge Maintenance. Frank P. McKibben & Walter Roof. *Welding Engineer*, Vol. 17, May 1932, pages 23-28.

The causes for alterations and repairs of bridges when they wear out or when loads increase, that is, corrosion, cracks due to overloading or to defective metal, or excessive stresses, are discussed and several examples described where it was possible by welding to carry out their alterations much more economically than could have been done by riveting. Details of the construction and welding methods are described and the importance of employing only capable welders pointed out. Ha (11c)

Application of Electric Welding in Crane Construction. (Anwendung der Elektroschweissung im Hebezeugbau.) A. Marschall. *Elektroschweissung*, Vol. 3, Aug. 1932, pages 149-150.

Discusses the advantages of electric welding in crane construction. The specifications for welding are tabulated. GN (11c)

On the Theory of Welded Joints. (Ein Beitrag zur Theorie geschweisster Verbindungen.) E. Melan. *Ingenieurarchiv*, Vol. 3, May 1932, pages 123-129.

The development of the theory of welded joints lags behind the practical application of welding. With the exception of a few investigations of one-dimensional problems (P. Fillunger: Über die Festigkeit von Löt- Leim- und Nietverbindungen, Oesterreichische Wochenschrift für den öffentlichen Baudienst, 1919) there is lacking up to the present time the theoretical treatment of even the simplest 2-dimensional problems as they are represented, for instance by joining a bar to a plate. There are to be found in the literature only a few most unsatisfactory solutions of this problem which are based on the theory of elasticity. The author gives the first fundamental mathematical solution of the theory of welded joints between a plate and a round bar. In his considerations the supposition is made that the weld seam possesses the same elastic properties as the base metal. This only holds approximately, but it is correct as far as the modulus of elasticity is concerned, which is of prime consideration. GN (11c)

Progress in Automatic Hydrogen Welding. Samuel Martin, Jr. *Iron Age*, Vol. 129, Mar. 3, 1932, pages 537-540.

In this method of welding an electric arc is established and maintained between 2 tungsten electrodes. Molecular H is fed into the arc. Atomic H welding affords a temperature of 4000° C. This method does not displace other methods but broadens the field of electric welding. Smooth and strong welds are produced. Considers some of the applications of this process in industry. VSP (11c)

Economy of Progressive and Retrogressive Welding in Built-Up Welds. (Wirtschaftlichkeit der Vorwärts- und Rückwärtsschweissung bei Auftragschweissungen.) Bardtke & Matting. *Autogene Metallbearbeitung*, Vol. 25, June 15, 1932, pages 184-187.

1 Tests were made with respect to gas consumption, time for preheating, welding, after-heating and hammering and the costs for the individual steps and the total welding were determined. It can be stated that the most favorable values were obtained for retrogressive welding without hammering. The expenses for preheating vary greatly according to the kind and size of the object. Retrogressive welding requires a shorter welding time and is a continuous process, while progressive welding can be carried out only with interruptions as the flame heats a small space before the seam which is built up and then the flame passes on to the next step. The economical advantages of the retrogressive welding method can be enhanced further if the piece can be preheated. Ha (11c)

Fabrication of Large Dairy Tanks Demands Expert Technique. L. E. Browne. *Steel*, Vol. 90, Feb. 15, 1932, pages 23-25.

A description of the 1000 to 5000 gal. capacity glass-lined tanks made of seamless welded Cr-Ni steel by the Pfaudler Co. for the ice cream and dairy industries. Includes 7 large photographs. JN (11c)

Electric Welding in Merchant Ship Building with Special Reference to the Specifications of the German Lloyd. (Elektrische Schweissung im Handelsschiffbau unter besonderer Berücksichtigung der Vorschriften des Germanischen Lloyds.) Burkhardt. *Elektroschweissung*, Vol. 3, June 1932, pages 108-112.

3 After a survey of American and English specifications, those of the German Lloyd from 1931 are discussed. The new German specifications contain fewer restrictions than the American and English ones. Illustrations of all-welded ships are shown. GN (11c)

Welding of Highly Alloyed Tool Steels. (Schweissen hochlegierter Werkzeugstahle.) H. Cegielski & J. Goleniewicz. *AEC—Mitteilungen*, May 1932, pages 184-185.

4 Millers of 22% W and 5% Cr steels could be satisfactorily welded and repaired by the "Arcatom" welding method; the fine-grained structure of the material was only little changed at the welded place and the hardness differed only inappreciably. Ha (11c)

The Economics of Quality Welding. R. E. Kinkead. *Welding Engineer*, Vol. 17, Jan. 1932, pages 43-44.

The author defines "quality welding" as a weld which is good enough for the purpose for which it is to be used. To do this it is necessary to have an exact knowledge of the service requirements, and of the stresses in the weld under
5 service conditions, and to be able to judge the life of the weld under any conditions. If these points are taken into account it is maintained great savings can be obtained as no excessive and superfluous care for the case in question is given to the weld. Ha (11c)

The Occurrences in the Welding Arc and Its Effect on the Welds Made with Bare and Coated Electrodes. (Die Vorgänge im Schweisslichtbogen und ihre Einfluss auf die Schweissungen bei blanken und umhüllten Elektroden.) W. Strelow. *Elektroschweissung*, Vol. 3, May 1932, pages 81-87.

6 The article first discusses the physical occurrences in the electric arc, with special reference to the emission of electrons and the deflection of the arc in the magnetic field as it is formed during welding near the elements of current which pass through the piece to be welded. Then follows a discussion of the formation of the fused weld by bare and coated electrodes. With bare electrodes it is to be expected that the arc is uniformly distributed over the area of the electrode. With coated electrodes the arc is restricted to the circumference of the coated shell for a long time. For both of the electrodes the course of voltage was studied by taking oscillograms. The drops of the weld metal are
7 much larger with coated electrodes than with bare ones. Coated electrodes offer the following advantage: The base metal adjacent to the weld seam is heated to a larger extent so that the seam does not cool so rapidly. The impurities of the fused metal thus have a better chance to separate. To this fact in particular, next to the favorable type of the formation of the weld drops, the greater purity of weld seams made with coated electrodes is to be attributed. GN (11c)

Economy in Welding Operations. E. Lunn. *Welding Engineer*, Vol. 17, Feb. 1932, pages 45-46.

8 The principal factors for economical welding are considered to be control of design, materials, welding wire, personnel, welding procedure and the inspection program. To neglect one of these may result in losses in raw material, labor, overhead, good will of the customer and trade reputation. Ha (11c)

Sheet Welding in Production. Earl Kelsey. *Welding Engineer*, Vol. 17, Apr. 1932, pages 42-43; *Welding News*, Vol. 3, Apr.-June 1932, pages 24-25.

Oxy-acetylene welding is the most satisfactory welding method for sheet metal utensils for holding liquids and which have therefore to be tight and are to be porcelain
9 enameled. Butt joints and flanged joints are used preferably, the latter especially for sheet thinner than No. 20 gage. The proper design and application of jigs is explained and the welding technique described. Ha (11c)

Control of Warping in Preheating for Welding. Jas. M. Vossler. *Modern Machine Shop*, Vol. 4, May 1932, pages 7-9, 14.

The author gives directions to avoid sagging or other deformations by building supports for castings when hot. Ha (11c)

Effect of Annealing on the Physical Properties of Welds. Thomas K. Vincent. *Welding*, Vol. 3, Aug. 1932, pages 463-465.

10 Tensile, Charpy impact and fatigue tests of welds in C steel and 3.5% Ni steel plates show that annealing at 600° C. reduces all of the physical properties slightly. Anvantages are gained in machinability and freedom from internal strains. The Charpy test is considered to be the most valuable. TEJ (11c)

Repairing Worn Shafts. (Herrichten abgenutzter Wellen.) A. O. Scholl. *Maschinenbau,* Vol. 11, Feb. 18, 1932, page 78.

2 axles of a heavy bending machine were worn out and had to be repaired without delaying production more than 3 days. It would have taken a full week to make and mount new axles. While the axles were revolving slowly they were electrically arc welded so that uneven heating was avoided. Thickness of the welded layer was about 1/5". New threads had to be cut. It took 7 hours to repair one. RFV (11c)

Welding Plate Beam Bridge. (Geschweisste Blechträger-Strassenbrücke.) H. Schütte. *Stahlbau,* Supplement to *Bautechnik,* Vol. 5, June 10, 1932, pages 89-91.

Calculation, design, welding and mounting of a road bridge. The bridge was electrically welded with coated electrodes. 4 references. GN (11c)

Remarks on the Application of the "Rules for Welded Steel Constructions," with Examples. (Ausführungen über die Anwendung der "Vorschriften für geschweisste Stahlbauten" mit Beispielen.) H. Schmuckler. *Elektroschweissung,* Vol. 2, July 1931, pages 127-139; Aug. 1931, pages 148-150.

This is a commentary on "Vorschriften für geschweisste Stahlbauten" (*Elektroschweissung,* Vol. 2, June 1931, pages 103-108) as they have been set up by the Fachausschuss für Schweisstechnik of the Verein Deutscher Ingenieure in coöperation with Ausschuss für einheitliche technische Baupolizeibestimmungen and the Deutschen Reichsbahngesellschaft. Part I refers to the practice to be followed in building construction, Part II to bridge construction. See also the paper by F. Merkel "Kritische Betrachtungen der Vorschriften für geschweisste Stahlbauten" (D I N 4100) *Elektroschweissung,* Vol. 2, Sept. 1931, pages 177-180. GN (11c)

Economics of Arc Welding. A. E. Steiger. *Mining Congress Journal,* Vol. 18, July 1932, page 36.

Discussion of practical economies derived from the use of arc welding. The greatest advantage of arc welding is that by its use repairs can be made without removing the parts which have failed. The writer sums up by saying that the arc weld is one, if not the most important, of repair tools. DTR (11c)

The Span-Weld System. E. F. Spanner. *Welder,* Vol. 3, June 1932, pages 1-5.

The problems of designing substantially flat steel plate diaphragms intended to resist pressures at right angles to their planes are discussed; such diaphragms occur in ship construction such as tank bottoms, tops and sides, or hull-plating. They are usually made up of a number of structural elements; a few methods of joining them are illustrated. Ha (11c)

Careless Welding Repair of a Boiler. (Unsachgemässe Kesselausbesserung mittels Schweissung.) *Zeitschrift des Bayerischen Revisionsvereins,* Vol. 36, Apr. 30, 1932, pages 97-98.

A case is reported on the repair of a ship boiler by electric welding. When the boiler was tested the welding proved to be faulty due to poor workmanship. GN (11c)

Arc Welding of High Conductivity Joints in Copper. T. C. Stuart. *Engineering Journal,* Vol. 14, Dec. 1931, pages 600-601.

The bus bars which flank the batteries of tanks in a Cu refinery and make electrical connection with the anode plates at one side and the cathode plates on the other require a high conductivity joint. The successful development of arc welding for this purpose is described. VVK (11c)

Multiflame Tips for Welding Torches. W. A. Slack. *Welding Engineer,* Vol. 17, Jan. 1932, page 42.

A few welding torches for production welding having 2 or 3 flame tips are described. Ha (11c)

Changes of State and Stresses During the Welding of the Steel Construction of the Switching Station at Stendal. (Zustandsänderungen und Spannungen während der Schweissung des Stahlbaues für das Reiterstellwerk in Stendal.) W. Schröder. *Der Bauingenieur,* Vol. 13, May 6, 1932, pages 268-272.

During the welding of the above construction there were studied in particular the effects of shrinkage of the weld seams on the changes in shape and the stresses set up in the various structural parts. Measurements were carried out at 9 different welded sections of the whole construction. The author emphasizes that in designing constructions to be welded it is a point of extreme importance to have a precise knowledge of the stresses and distortions which can be caused during the later performance of the welding. GN (11c)

Electric Welded Pipe Line in Cairo. E. Tutt. *Welder,* Vol. 3, June 1932, pages 22-25.

Details of shipping, erecting and welding of 155 pipes of 6" length each are described; the diameters vary from 0.9" to 1.8", the wall thickness from ¼" to ⅜". Ha (11c)

Manufacturing Steel Pipe in Japan. Maurice Taylor. *Steel,* Vol. 89, Dec. 7, 1931, pages 31-33.

A description of the automatic shielded arc-welding process installed in the plant of the Kawasaki Dock Yard Co., Ltd., Kobe for making pipe of 1300, 1500 and 2100 mm. diam. and of the shielded arc process used for joining sections of pipe in the field. The present status of welding in Japan is discussed. JN (11c)

Factors Affecting the Welding Qualities of Steel. W. E. Stine. *Yearbook American Iron & Steel Institute,* 1931, pages 486-510; *Engineering,* Vol. 133, Feb. 19, 1932, page 235.

See *Metals & Alloys,* Vol. 3, Mar. 1932, page MA 71. (11c)

Electrically Welding Gasometers. (Elektrisches Schweissen von Gasbehältern.) Schuster. *Gas und Wasserfach,* Vol. 75, Aug. 13, 1932, page 669.

Dutch experiences in repairing gasometers by welding. Welding proved satisfactory in technical regard, the costs of welding were rather high. GN (11c)

Electric Current Supply for Welding. D. A. Trickett. *Welder,* Vol. 3, June 1932, pages 30-32.

The power cost per 1000 hours for an arc of 100 amp. and 20 volts is tabulated for different types of generators. The lowest cost, £13 10s, was obtained with a machine of an inherently drooping characteristic from 60 to 20 volts with an overall efficiency of 62%, while the highest was £62 for a level compound machine with a series resistance in the weld circuit. Ha (11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

1 **A New Method for Production of Completely Deoxidized Iron Castings of Low Sulphur Content. (Ein neues rationelles Verfahren von vollkommen entoxydiertem Eisenguss von geringem Schwefelgehalt.)** W. Haüly. *Schweizerische Technische Zeitschrift,* Vol. 29, May 5, 1932, page 277.

As a result of many years of practical and scientific research a new method has been developed for the production of Fe and steel with low S content. The paper gives no detailed information on the new process but states that it can be used for melts made in both the cupola and the open hearth furnace. The S content could be decreased from, for instance, .15% to less than .035%. The method 2 can also be used in adding the alloying elements in making special alloys; practically without any loss of the alloy added. The elimination of O is performed in the ladle by a special deoxidizing alloy. There are added about 2 oz. of this deoxidizing alloy per ton of metal. By this method castings are claimed to be obtained absolutely free of segregations. GN (12a)

Re-melting of Electrolytic Nickel. (Umschmelzbehandlung von Elektrolytnickel.) *Die Metallbörse,* Vol. 22, Apr. 23, 1932, page 515.

Note on tests of Kuznetzov & Baranov (*Sobshenia Vsesouznogo Istituta Metallov,* 1931, pages 93-104) who aimed at a 3 determination of the factors responsible for the irregular properties of remelted electrolytic Ni. The duration of the remelting procedure exerts a decisive influence on the properities of Ni due to an increase of the content of the low oxide of Ni. Maintaining a temperature slightly below the m.p. for 2 hours, succeeded by 10 min. in the liquid state, the NiO content amounted to 2.45-2.64% and to 5.85-6.1% after 50 min. C seems to furnish a suitable deoxidizer, but a surplus tends to graphite formation at the grain boundaries. Mn tends to form Mn oxide which impairs the physical properties, but Mn removes dissolved gases and S. Mg 4 yielded still better results as a desulphurization means. The authors suggest an addition of 0.5% charcoal. After the C content dropped to 0.1% an addition of 0.3% Mn (0.2% Mn in case of Ni later used for forging purposes) is employed. Finally 0.1-0.14% Mg are introduced as a Ni-Mg intermediary alloy. EF (12a)

The Refining of Nickel. (Zur Raffination des Nickels.) E. T. Richards. *Die Metallbörse,* Vol. 22, May 28, 1932, pages 673-674.

The effect of S, C, Si, H_2 (electrolytic Ni), O_2 (deoxidized with Mg) and Ni sulphide (Merica & Waltenberg) on the ductility of Ni is dealt with. Stress is laid on the 5 detrimental effect of S due to the low solubility of sulphides in Ni (0.005%), their low m.p. (Ni-NiS eutectic at 620° C.) and their accumulation at the grain boundaries. The inferior properties of S bearing Ni at elevated temperatures are self-explanatory. The m.p. of Ni oxide is 1650° C., while the Ni-NiO eutectic melts at about 1400° C. as compared with 1450° C., the m. p. of pure Ni. At low concentrations, O_2 does not exert a very harmful effect on the physical properties. But this does not hold true for less pure commercial brands which contain Fe, Si and Mn up to 1% and over. They absorb more O_2 and show a 6 different micro-structure. But even at the eutectic content of 1.10% O_2 the detrimental effect is not extraordinary. A table is presented showing the 3 American Standards according to the U. S. Federal Specification Board, No. 371, 1926. The German Standards allow the following maximum contaminations: 98.5 Ni + Co, 0.15 Cu, 0.50 Fe, 0.20 Si, 0.03 As, 0.03 S, 0.3 C and only traces of P, Mn, Sn, and Sb. The refining process of Ni does not offer great difficulties. The remaining percentages of Fe, Co, Mn, Cu, As, Sb, Pb and Zn are indifferent with respect to most of the commercial applications. Cu must be absent if Ni is used for galvanoplastic purposes. Si forms a silicide which only induces 7 brittleness at higher concentrations. Fe in larger percentages increases the resistance towards oxidation. The 2 steps of the refining process of Ni (a) the deoxidation by Mn. Mg, and charcoal and (b) the desulphurization are fully dealt with. The drawbacks of Mn for both purposes are pointed out, while the application of 0.15-0.20% Mg for the refining process are strongly recommended. Sometimes Mn is used as a deoxidizer (0.2%) followed by the desulphurization by Mg (0.1%). The latest suggestions of Kutzenow & Baranov (Abstract above) are critically discussed in conclusion. 8 EF (12a)

Casting & Solidification (12b)

Melting and Casting Nickel-Silver Alloys. Edmund R. Thews. *Metallurgist,* Feb. 1932, pages 21-22.

Recommended practice for melting and casting Ni-Ag alloys is as follows: Cu, Zn, and Ni should not be added as such in making up the charge but the Ni or suitable Ni-Cu alloys should be alloyed with brass and the brass added to the charge. All the components of the mixture are added at once. As soon as the charge commences to melt, a few 9 handfuls of table salt or sea salt are thrown into the crucible and heating continued until the metal is thoroughly fluid. The best pouring temperatures usually lie about 300° F. (150° C.) above the melting point of the alloys handled. At this temperature about ¼ oz. Al/100 lb. of metal is added for deoxidation purposes and the metal is then poured without delay. Successful pouring of the alloys is dependent on the maintenance of a narrow range of temperature depending on the composition of the alloy. Molds and cores should be made of fine, highly refractory sand, moderately moistened and for facing material a 30 : 1 mixture of finest sand 10 with graphite will improve the smoothness of the casting surface. In sand castings the shrinkage of Ni-Ag averages 1.8%; chill castings about 2%. Chill molds are preferably filled from below and held for 30 minutes. The mold walls are coated with a mixture of turpentine and lampblack applied by a brush. VVK (12b)

The Action of Cast-in Chills on the Density and Strength of Castings of Bessemer Steel. (Die Einwirkung von eingegossenen Kühlkörpern auf die Dichte und Festigkeit von Bessemerstahl-Gussstücken.) E. LANZENDOERFER. *Die Giesserei*, Vol. 19, May 13, 1932, pages 181-186.

Cooling bodies are often used for the elimination of formation of pipes as they withdraw heat from the molten steel during pouring into the mold so that the steel crystallizes onto the cooling material. Such cooling materials can be made of simple nails, pieces of Fe, spirals, etc. The behavior was investigated by casting at 1600° C. cooling bodies of 80 mm. length and 8 x 8 mm. section, 32 g. weight, into castings of different sections and 80 mm. height; the surface of the cooling nail was rusty, clean and tinned with different compositions of a Sn-Pb alloy. The casting was subject to tensile tests and the surface examined microscopically. The results are given in detail. It can be stated that the application of cooling pieces is of advantage in all cases where pipes can be expected in a casting due to its complicated shape, especially where many bosses or flanges have to be cast on so that it would not be economical to provide so many gates. Although the strength and density of the casting is generally not very much impaired and the formation of pipes often prevented, gates should preferably be provided instead of cooling pieces when a casting has to be of best quality as cooling bodies always leave some uncertainty as to the result. Ha (12b)

Rolling (12c)

Lubrication of Roll Neck Bearings Requires Special Attention. RALPH C. WALTER. *Steel*, Vol. 90, Feb. 1, 1932, pages 31-33.

A discussion of the special lubrication problems involved in handling antifriction bearings of large size and capacity such as those developed for use in four-high, continuous, hot strip mills for rolling steel plate. JN (12c)

Application of Tapered Roller Bearings in Merchant Bar Mills. S. M. WECKSTEIN. *Transactions American Society of Mechanical Engineers*, Vol. 54, Apr. 30, 1932, Iron & Steel, pages 29-35.

Details of construction, field of application, experiences in operation and comparisons with other types of bearings are compiled; considerable power savings were made due to elimination of friction losses and also due to smaller driving motors. Ha (12c)

Roll Pass Design. XXXVII-XI. W. TRINKS. *Rolling Mill Journal*, Vol. 6, Jan. 1932, pages 15-17; Feb. 1932, pages 55-58, 65; Mar. 1932, pages 103-106; Vol. 7, No. 1, 1932, pages 25-30.

Outlines methods of rolling I-beams and factors which determine the methods that may be employed for each size of beam. Discusses diagonal, Slick, and universal-mill methods of rolling I-beams; rolling wide I-beams with narrow flanges; rolling small and large T-shapes; rolling T-sections on the diagonal; and methods of rolling rails. MS (12c)

Application of Impregnated Fabric Bearings to Roll Necks. ARTHUR J. SCHMITT. *Transactions American Society of Mechanical Engineers*, Vol. 54, Apr. 30, 1932, Iron & Steel, pages 25-27.

Results of tests with bearings of celeron which consists of sheets of woven fabric impregnated with resin are given. The hardness of the material is about 40 Brinell, its compressive strength is about 35,000 lbs./in.^{2}, its tensile strength 17,000 lbs./in.^{2} The load carrying capacity ranges from 1,000 to 2,500 lbs./in.^{2} of projected bearing area. The celeron bearing can be lubricated with water but oil or grease improves the performance appreciably; it is most efficiently used on highly polished roll necks with great savings in power cost and many times the life of a metal bearing. Details of construction are described. Ha (12c)

Notes on Chilled Rolls and Their Subsequent Failure in Service. D. J. THOMAS. *Blast Furnace & Steel Plant*, Vol. 20, Feb. 1932, page 200; Mar. 1932, page 288; Apr. 1932, page 364; May 1932, page 448.

Chief cause of the breakage of rolls is uneven or eccentric chill. Irregular chill is due to the unequal departure of the roll body from the chill mold during contraction. As a means for holding the roll centrally within the mold, so that even chilling can take place, the usual molds have a number of beveled grooves bored in the inner circumference. 2 are placed equidistant from the upper end, and 2 are placed equidistant from the bottom end. Thus, corresponding projections are formed on the surface of the roll bodies when the rolls are cast. During shrinkage, beveled edges of projections bear on the beveled edges of the grooves, causing the roll to depart from all sides evenly. Projections on largest roll should be not more than 3/16". MS (12c)

Modern Processing of Threads. (Moderne Gewindeherstellung.) A. PAMPEL. *Werkzeug*, Supplement to *Maschinenkonstrukteur-Betriebstechnik*, Vol. 8, May 10, 1932, pages 56-57.

The paper shows that threads are more accurately made by rolling than by cutting. GN (12c)

Plastic Deformation in Theory and Experiment. *Metallurgist*, Feb. 1932, pages 22-24.

Extended abstract of a paper by E. Siebel, *Stahl und Eisen*, Vol. 50, Nov. 26, 1931. See *Metals & Alloys*, Vol. 3, July 1932, page MA 220. VVK (12c)

Reconstruction of a Three-High Mill for Rolling Wide Strip or Bar Iron. (Umbau einer Triostrasse für Walzung von Breitem Bandeisen.) L. PLETSCH. *Stahl und Eisen*, Vol. 52, June 9, 1932, pages 563-565.

Description of the rebuilding of the 3-high mill in the Werke Javornik (Südslawien) to permit rolling of bar Fe or Fe strip up to 420 mm. wide and 2 mm. thick. Fe plate 35 mm. thick and 1500 mm. long were used for producing the finished products. Automatic passage of the material was used and the general 3-high mill features were retained. A second heating furnace was necessary due to the increased rate of production. DTR (12c)

A New Separating Machine for Finished Sheets. F. CHRIST. *Engineering Progress*, Vol. 13, June 1932, pages 129-130.

See *Metals & Alloys*, Vol. 2, Dec. 1931, page 313. (12c)

Cold Rolled Metals. A. L. MOLINEUSE. *Metal Industry*, London, Vol. 40, Jan. 15, 1932, pages 93-96.

Apparatus used in the production of cold rolled sheet and strip is described. The high "1931" standard of surface, flatness and accuracy are discussed. PRK (12c)

Development of New Equipment. GEORGE T. LADD. *Blast Furnace & Steel Plant*, Vol. 20, Mar. 1932, page 280.

Outline of rolling-mill equipment installed in 1931 or under construction at present by the United Engineering & Foundry Co. MS (12c)

Electrical Developments in 1931. A. F. KENYON. *Blast Furnace & Steel Plant*, Vol. 20, Jan. 1932, pages 56-57.

Reviews application of electric drives to rolling mills of the Illinois Steel Co., Duquesne plant of the Carnegie Steel Co., Ellwood City works of the National Tube Co., Algoma Steel Corp.'s Sault Ste. Marie Mill, Republic Steel Corp. and a sheet mill. These were or are being installed by the Westinghouse Electric & Mfg. Co. MS (12c)

Metal Rolling in Mass Production. JAMES R. CORNELIUS. *American Machinist*, Vol. 76, Jan. 7, 1932, pages 2-7.

Describes and illustrates cold rolling processes as practiced in England. Describes some of the machines used. RHP (12c)

Influence of Temperature and Foreign Metals on the Rolling of Zinc. (Einfluss von Temperatur und Fremdmetallen auf die Walzbarkeit von Zink.) O. BAUER & P. ZUNKER. *Metallwirtschaft*, Vol. 11, May 20, 1932, pages 289-292; May 27, 1932, pages 303-306.

7 references. 2 grades of Zn were used, refined Zn containing 1.12% Pb and .11% Cd, and electrolytic Zn containing .015% Pb. Test sheets 8 mm. thick were reduced by rolling in .2 mm. steps. The ease of rolling increases regularly with increase in temperature for both grades of Zn. Below 110° C. good results cannot be obtained, the sheets crack. At 110° and 130° a few small cracks appeared in the refined Zn, but disappeared at 150°. The claim of other investigators that rolling temperatures of 120° to 140° were particularly unfavorable were found to be not true. With increasing amount of deformation and rolling temperature the coarse casting structure changes to a fine grained rolled structure. The start and finish of this change occurs at a lower temperature in electrolytic Zn than in refined Zn. The addition of Pb to electrolytic Zn has no influence on the ease of rolling. The other metals were added to refined Zn only. Cd is harmful if present above its solubility in Zn, which is .25% at room temperature. Cu does not influence the ease of rolling provided the temperature is above 110°. Fe above .1% is harmful unless the rolling temperature is above 150°. Sb has no effect provided the temperature is high enough. Sn is the most harmful of any of the metals tested. Even .1% produces cracks and its effect is not overcome by higher rolling temperatures on account of the eutectic it forms with a low melting point. CEM (12c)

Push Bench Process for Manufacture of Seamless Tubes. WM. H. ENGELBERTZ. *Rolling Mill Journal*, Vol. 6, Mar. 1932, pages 91-96.

Discusses the development of the modern push bench process or the so-called improved Ehrhardt process. Billet is perforated in a hydraulic punching press. Hollow cylinder is then stretched over a long mandrel on a push bench. Tube passes through a reeling machine which loosens the tube on the mandrel and evens and smooths the tube wall. Tube then passes through a set of sizing rolls, and, after leaving the cooling rack, is straightened in a set of cross rolls. Advantages of push bench process are its high output and low production costs. For economical reasons no tubes under 2½" outside diameter are made on the push bench. If products of smaller diameter are required, tubes from the push bench are reheated and passed through a reducing mill. Tabulates output of small type push bench plant. Comparison of the costs of production of tubes by the push bench, butt-weld and electric-weld processes shows that only the continuous butt-weld mill (Moon) can produce a cheaper product than the push bench. MS (12c)

Sheet and Tinplate Rolls. J. SELWYN CASWELL. *Blast Furnace & Steel Plant*, Vol. 20, Jan. 1932, page 111.

Part of an abstract from *Proceedings South Wales Institute of Engineers*, Vol. 46, pages 310-432. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 11. MS (12c)

Aluminium Sheet Production. Part XIII. Finish Rolling. ROBERT J. ANDERSON. *Metallurgia*, Vol. 6, May 1932, pages 11-14; June 1932, pages 45-48; July 1932, pages 85-86; Aug. 1932, pages 121-122.

A detailed description of equipment and technique. JLG (12c)

Lignum Vitae Bearings for Roll Necks of Medium-Sized Rolling Mills. K. W. ATWATER. *Transactions American Society of Mechanical Engineers*, Vol. 54, Apr. 30, 1932, Iron & Steel, pages 1-2; abstract, *Rolling Mill Journal*, Vol. 7, No. 1, 1932, pages 19-20.

The often unsatisfactory performance of metal roll-neck bearings is pointed out and the experiences with bearings of various species of lignum vitae described. They were cooled by water spray. The rate of wear and the power loss in friction were found to be considerably lower than in metal bearings with oil or grease lubrication. Savings in power up to 23% and a 15 times longer life than in metal bearings were observed. MS+Ha (12c)

Machining (12g)

Electrical Testing Equipment for Machine Tools. (Elektrische Prüffeldeinrichtungen für Werkzeugmaschinen mit Einzelantrieb und für Werkzeuge.) E. LÖTTERLE. *Werkzeugmaschine*, Vol. 36, May 31, 1932, pages 175-178.

Detailed description of all the various electrical instruments used to supervise the performance of machine tools. There are also discussed the methods for supervising the performance of the tools used for machining, for measuring the cutting speed, electrical measuring boxes and electrical torsional dynamometers for measuring the cutting pressure, optical and mechanical measuring instruments for studying the cutting performance of the tool. It is emphasized that such equipment cannot be dispensed with for supervising and improving the quality. GN (12g)

The Newer Cutting Tool Materials. A. L. De Leeuw. *Mechanical Engineering,* Vol. 54, May 1932, pages 329-334, 353.

The outstanding materials for modern cutting tools are W and Ta carbides which do not lose their hardness until at a very high temperature. They are sintered materials and have therefore not the strength of solid metals. W carbide shows an affinity for steel which causes small pieces of it to weld to the tool. These properties required the development of a special technique for the support and arrangement of the tools; the practices for various kinds of metal working are described. Ha (12g)

Haynes Stellite Cutting Tools. W. A. Becker, E. E. Gordon & W. A. Wissler. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 93-100.

Haynes stellite is a non-ferrous alloy consisting essentially of Co, Cr and W. The cutting material most used, Stellite No. 3, has the following physical properties: Brinell 600, Rockwell C 61, tensile strength 38,000 lbs./in.^{2}, compressive strength 311,000 lbs./in.^{2}, cantilever strength ½ in.^{2}, 1 in. overhang, 2500 lbs. Its most important property is red-hardness which was tested up to 1100° C.; at 850° C. it is still 49 Rockwell C. Used for milling it shows a decided superiority over high-speed steel; it can be used equally well for cast Fe, semi-steel, malleable Fe, bronze, etc. It is not good for automatic or semi-automatic cutting machines. The manner of using it in different machining operations is described. See also *Metals & Alloys,* Vol. 2, Feb. 1931, page 43. Ha (12g)

Tool Steel Tools. A. H. D'Arcambal. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 101-109.

The 3 factors which govern the life of tool steel tools are proper design, kind of steel used, and treatment. The progress made in materials for machining and preparing machine tools is reviewed. See *Metals & Alloys,* Vol. 2, Feb. 1931, page 44. Ha (12g)

Time Calculations in Machining. (Il calcolo dei tempi nelle lavorazione meccaniche.) T. Bruzzone. Ulrico Hoepli, Milan, 1932. Paper, 6½ x 9½ inches, 105 pages. Price 15 Lire.

Deals with calculation of proper machining speeds, feeds and depths of cut for various types of machining operations on hard iron, steel of various tensile strengths, gray iron, bronze and brass, according to the methods of Taylor. Nomographic charts are provided and a slide rule, similar to that of Barth, is described. One example assumes the use of "superior high speed steel" of 17.8% W, 5.9% Cr, 0.93% V, which would indicate the use of higher Cr in Italian high speed steel than is customary here. Tungsten or tantalum carbide tools are not dealt with. H. W. Gillett (12g)-B-

Manufacturing Dies and Molds by the Hobbing Process. L. Doerfler. *Modern Machine Shop,* Vol. 5, July 1932, pages 12-17.

Dies and plastic mold cavities are readily reproduced by means of a "hob" upon which is duplicated, in shape and surface details, the design of the piece that is to be made. This hob is forced cold into a cold block of steel to the necessary depth to obtain the impression desired. The process and the method of working are described in detail. Ha (12g)

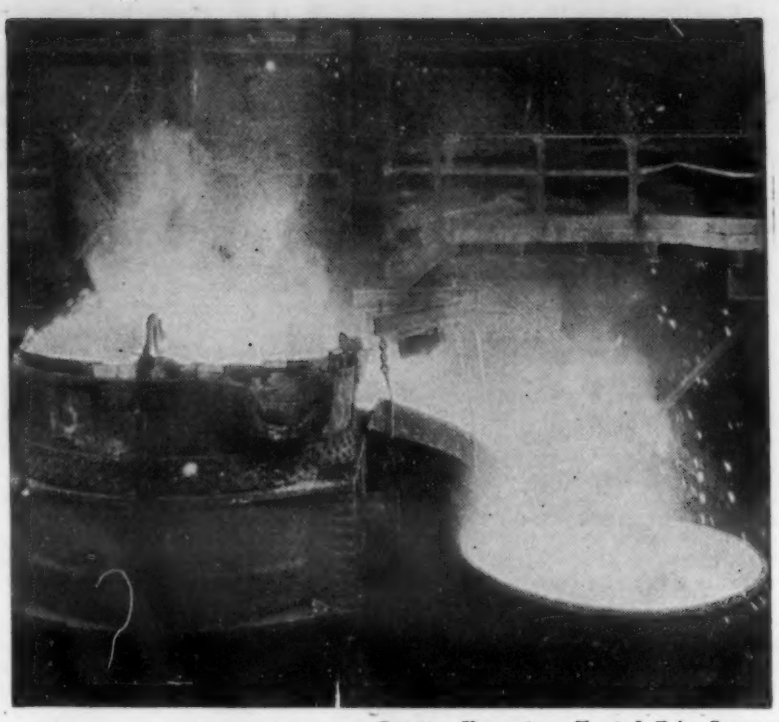
Machining Properties of Some Cold-Drawn Steels. O. W. Boston. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Machine Shop Practice, pages 41-55.

See *Metals & Alloys,* Vol. 2, Feb. 1931, page 44. Ha (12g)

Machining an Aluminum Piston. A. P. Gwiazdowski. *American Machinist,* Vol. 76, Feb. 25, 1932, pages 264-266.

Discussion of the various machining operations dealing with machining cycles, clutching positions, speeds and feeds, and diamond boring of the wrist pin holes. RHP (12g)

Working of Glass with Widia Tools. (Bearbeitung von Glas mit Widia Werkzeugen.) A. Fehse & B. Kindt. *Glastechnische Berichte,* Vol. 10, Apr. 1932, pages 193-200.



A very great number of examples and photographs show the applicability of Widia (tungsten carbide) tools for the shaping of glass. As it is extremely difficult to give bodies of pressed or cast glass the exact shape desired they can now be machined to exact dimensions easily and cheaply. Rough turning can be done with a chip of 3 mm., finishing usually with 0.1 or 0.2 mm. The cutting velocity is 60-100 m./min. As a particularly interesting piece of work of machined glass the photograph of a calendar of glass is shown. Ha (12g)

Influence of Chemical Composition and Heat Treatment of Steel Forgings on Machinability with Shallow Lathe Cuts. T. G. Digges. *Transactions American Society of Mechanical Engineers,* Vol. 54, Feb. 15, 1932, Machine Shop Practice, pages 49-59.

See *Metals & Alloys,* Vol. 2, Nov. 1931, page 271. Ha (12g)

Is there at Present any Unique Factor for Valuation of High Speed Tool Steels? (Gibt es heute schon einen einheitlichen Wertmesser für Schnelldrehstähle?) A. Hofmann. *Maschinenbau,* Vol. 11, Feb. 4, 1932, pages 45-46.

The value of high speed tool steels is dependent on the percent of its alloy constituents and on the melting practice in the steel plant. The influence of the various elements is explained in detail. W must be present by more than 14% to guarantee sufficient stability at high temperatures. To use more than 22% would be wasteful because of the excessive carbides not being dissolved in the solid solutions. To get the full effect of the important W content, 4-6% Cr and 0.6-0.85% C must be present for formation of the necessary carbides. Above this percentage of Cr and C, tools turn brittle and incline to cracking. More than 1% Mo is dangerous by increasing grain size and corresponding brittleness. V is very valuable for its deoxidizing effect and its rendering the steel less sensitive. It substitutes for or supports the effect of W to some extent. As much as 3% are used. Co is added up to 6% in American practice, in Germany up to 10% and in England as high as 20%. Tempering stability and heat conductivity are chiefly improved. To exceed 10% is said to be uneconomical. Ta and Ti carbides are mentioned as further bettering the quality. The importance of the melting, pouring and subsequent rolling or forging practice are pointed out. It is shown to be wrong to judge the grade of tools by the amount of their so-called alloy units, counting 1% W as 1 unit, 1% Co as 7.5 units, etc., but no other standard of valuation is offered. Quality Specifications for Tools. (Gütevorschriften für Werkzeuge.) Fetzer. *Das Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 65, Apr. 10, 1932, pages 41-42.

Paper stresses importance of cöoperation between manufacturer and consumer. GN (12g)

Influence of the Shape of the Chip on the Cutting Speed. (Einfluss des Spanquerschnitts auf die Schnittgeschwindigkeit.) S. F. Gleboff-Heintz. *Die Werkzeugmaschine,* Vol. 36, Aug. 15, 1932, pages 275-278.

The paper discusses the question whether, in studying cutting pressure and cutting performance of a tool, it is sufficient, according to the proposal of Nicholson, to consider the cross-section of the chip as the one variable value or whether it is necessary to simultaneously consider feed, depth of cut, thickness and width of cut, cutting angle, etc., as Taylor has done. The author calculates the error when the Nicholson method is used instead of the Taylor method. GN (12g)

The Roughness of Machined Metallic Surfaces. (Die Rauhigkeit bearbeiteter Metallflächen.) W. Fritz. *Forschung (Zeitschrift Technische Mechanik und Thermodynamik)* Vol. 3, Mar.-Apr. 1932, pages 103-106.

The paper deals with the practical suitability of the various methods of studying the surface condition of machined surfaces of metals. (1) The cast method (gelatin) is applicable when, without claim to a high degree of accuracy, an approximate insight into the roughness of the surface is desired. (2) The optical (reflection) method is suitable for comparative measurements on ground surfaces (glass) when the unevenness is in the limits of from 2-6 μ. The method fails for quantitative determinations of roughness. (3) The mechanical (touch) method with photographic recording is most adaptable. The results of tests on steels, gray cast Fe, red brass and Lautal are reported. For brass, drawing and rolling give about the same roughness. 2 references. GN (12g)

Cutting Diamonds. (Schneiddiamanten.) B. Fetzer. *Werkzeugmaschine,* Vol. 36, May 15, 1932, pages 159-161.

The paper first discusses the points which are to be borne in mind in selecting diamonds for cutting tools. The capacities and properties (hardness, elasticity, effect of temperature, admissible cutting speed, feed, depth of cut and cutting performance) of high speed steel, Widia and diamond are dealt with and compared. For a successful use of diamonds it is of extreme importance to choose the depth of cut and the feed as low as possible but the speed of cutting as high as possible. The duration of life of the diamond essentially depends on a careful fastening of the diamond on the tool shank. The cutting angles are given. The most favorable conditions for turning and drilling the various metals, alloys and other materials with diamonds are tabulated. GN (12g)

Drawing & Stamping (12h)

Die Pressing of Brass and Copper Alloys. John R. Freeman, Jr. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 329-335.

Includes discussion. See *Metals & Alloys,* Vol. 2, Mar. 1931, page 72. (12h)

The Use of Hard Metals in the Wire Drawing Trade. (Die Verwendung von Hartmetallen im Drahtziehereigewerbe.) C. Agte. *Die Werkzeugmaschine,* Vol. 36, Aug. 15, 1932, pages 281-283.

Outline of the use of Widia and similar hard metals for drawing dies and accessories such as gages, pliers, etc. Data on capacities are given. The power consumption in drawing through hard metal dies essentially depends on the lubrication. Die angles for various ferrous and non-ferrous metals are tabulated. Products drawn with such type dies are distinguished by highest accuracy of dimensions. GN (12h)

Advantages of Uniformity in Cutting and Stamping. (Vorteile der Vereinheitlichkeit beim Schnitt- und Stanzenbau.) A. Peterhans. *Werkzeug,* Supplement to *Maschinenkonstrukteur-Betriebstechnik,* Vol. 8, June 10, 1932, pages 71-74.

Wire: Machine and Single-Hole Drawing. Richard Saxton. *Metallurgia,* Vol. 6, Aug. 1932, page 120.

Multiple die machines are not satisfactory for drawing high-strength wire because of the fatigue stresses set up at each reduction which can only be removed by allowing the wire to stand an hr. or so between draws. JLG (12h)

The Knowledge of Structure Displacement in Shaping and Its Utilization to Tool and Material to be Shaped. (Die Erkenntnis der Gefügeverschiebung beim Umformen und deren Nutzanwendung auf Werkzeug und Werkstoff.) Max Thiele. *Zeitschrift für wirtschaftliche Fertigung,* July 1932, pages 78-83.

Theoretical and practical considerations on various shaping processes with special reference to the flow of material in stamping and drawing. GN (12h)

The Distortion of Wires on Passing Through a Draw Plate. G. I. Taylor & H. Quinney. *Institute of Metals, Advance Copy* No. 618, Sept. 1932, 13 pages.

Semicircular wires of ⅛" diameter were engraved with straight lines parallel and perpendicular to their axes. Pairs of these wires were drawn through dies and the distortion of the lines determined. When drawn through 3° dies the distortion of the lines produced by each pass diminished, and increased distortion did not occur after the 4th pass. Wires were also drawn through dies having increased tapers. As the angle increased distortion increased. Results are shown by curves and are analyzed mathematically. JLG (12h)

Cold Working (12j)

Forces and Power Requirements for Cold Drawing Wire. J. H. Hitchcock. *Rolling Mill Journal,* Vol. 6, Feb. 1932, pages 67-70; Mar. 1932, pages 107-110.

Summarizes results of recent research work in England and Germany. 5 references. MS (12j)

The Influence of Cold Work on the Strength of Brass and the Possibility of an Improvement by Heat-treating. (Der Einfluss der kaltmechanischen Bearbeitung auf die Festigkeit und die Möglichkeit einer Vergütung durch eine entsprechende Wärmebehandlung.) F. Freude. *Die Metallbörse,* Vol. 22, Feb. 20, 1932, pages 225-226.

Residual stresses from cold working of 70/30 brass led to failure in service. Tests on the remaining stock were performed to ascertain the cause of trouble. Etching in mercury nitrate for 15 min. resulted in cracking of the tube samples. Further experiments on cold-drawn 60/40 Cu-Zn alloys were carried out and the internal stresses were determined. A thermal treatment at 150° C. resulted in a material reduction of the residual stresses which were almost entirely released after the same samples were exposed to 250° C. for 3 hours. The strength properties were not affected by this heat-treatment. Comparative tests on a 64/36 and 70/30 Cu-Zn alloy yielded the same result. EF (12j)

Hammering and Forming of Sheets. (Martelage et Façonnage des Toles.) G. Dubois. *Cuivre et Laiton,* Vol. 5, June 15, 1932, pages 245-254.

The practice in Cu boiler shops is discussed and the laying out of shapes, the required material, shaping by hammering and the joining of the parts is described in detail and procedures illustrated by sketches and photographs. The author recommends the application of more engineering principles to operate more economically than is possible with the present rather arbitrary methods. Ha (12j)

Mathematical Derivation of Machine Time for Cold Rolling Mill Machines. (Rechnerische Ermittlung der Maschinenzeit an Kaltwalzwerksmaschinen.) Karl Veit. *Stahl und Eisen,* Vol. 52, June 23, 1932, pages 617-618.

In a cold strip mill the time consumed on any machine may be computed mathematically. For example, on the cold rolls, given rolling diameter (d) and R.P.M. (η) of the rolls, the time is given by $t = \frac{100}{d \times \pi \times \eta}$, where t is machine time in min./100 m. length of strip. Rolling time is tabulated for different gage strip, from 0.2 to 2 mm., and for strip widths from 10 to 50 mm., for 100 kg. strip rolls. DTR (12j)

Cleaning (12k)

Degreasing in Chromium Plating. (Die Entfettung in der Chrom-Galvanotechnik.) Richard Justh. *Feinmechanik und Präzision,* Vol. 40, June 1, 1932, page 105.

Cleaning of Castings by Means of a Mixture of High Pressure Water and Sand. (Putzen von Gusstücken mittels eines Druckwasser-Sandgemisches.) Fr. Huth. *Emailletechnische Monatsblätter,* Vol. 8, Aug. 1932, pages 60-61.

A simple apparatus is described, recently constructed by a German foundry, in which the coarse quartz sand used for cleaning, and the fine-grained molding or core sand are recovered separately. GN (12k)

The Degreasing of Metal Parts and Quality Wares before Electroplating. (Einiges über die Entfettung von Metallteilen und Massenartikeln vor der Plattierung.) K. Altmannsberger. *Oberflächentechnik,* Vol. 9, May 3, 1932, pages 88-89.

The most used degreasing method is now the electrolytic which is often combined with a preliminary Cu-plating. A bath for this purpose with Fe anode is 4.25 kg. NaOH, 4.25 kg. calcined soda, 0.70 kg. sodium silicate, 0.20 kg. Al-silicate, 0.70 kg. Na-cyanide and 0.70 kg. cupro-cyanide. The mechanical and chemical methods of degreasing for small articles are briefly treated. Ha (12k)

DEFECTS (13)

Inclusions and Their Effect on Impact Strength of Steel. I, II. A. B. KINZEL & WALTER CRAFTS. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 95, 1931, pages 143-180, 181-195.

Includes discussion. See *Metals & Alloys,* Vol. 2, July 1931, page 136; Dec. 1931, page 315. (13)

Fractures in Boiler Metal. A. E. WHITE & R. SCHNEIDEWIND. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Fuels & Steam Power, pages 193-214.

A review of metallurgical examinations of a great number of failures of boiler materials is given and from it a classification as to the causes of failure was attempted. Bending, compression, tension and impact, all produce fractures predominantly through the grain; failure in such cases is accompanied by deformation of the crystals. Impact failures under some conditions may be produced with very little deformation. Fatigue cracks are always transcrystalline without deformation of the grain. Caustic embrittlement, due to alkaline liquors, produces intercrystalline cracks. The cause of many failures can be more or less satisfactorily traced by comparison with fractures produced in the laboratory. Ha (13)

CHEMICAL ANALYSIS (14)

Extension of the Customary Scratch Test for a Rapid, Approximate Determination of the Gold Contents of Gold Alloys. (Erweiterung der bisher üblichen, sogenannten Strichprobe, zur schnellen, annähernden Prüfung des Feingehaltes von Goldlegierungen.) GEO. BUCHNER. *Oberflächentechnik,* Vol. 9, May 3, 1932, page 89.

Making a scratch test with the Au alloy on a test stone and observing its reaction with certain acids, is reliable only if there are only Au, Cu and Ag present, but not as is the case in modern jewelry, Pt, Pd, Ni and others. A modification of this test permits dissolving all additions and determining the Au chemically. For Pt-addition a precipitation as K_2PtCl_6 is made. Ha (14)

Spectrum Analysis in Metallurgy. C. E. EDDY. *Chemical Engineering & Mining Review,* Vol. 24, Apr. 5, 1932, pages 239-240.

A brief review of the work done on the determination of Pb, Sn, Fe, Ni, Al, and Mn in brass by means of the spectrum. Also of Sn, Sb, Cd, As, Bi, Cu, Zn, and Ag in Pb alloys. The accuracy in estimation by optical methods is about 10% of the amount of the element present—amply sufficient for ordinary production control. Simultaneous determination of 2 or more constituents is a favorable feature of the method. An analysis requires about ½ hour, compared to 5 or more hours for a chemical analysis. WHB (14)

The Determination of Beryllium in Highly Alloyed Steels and in Ferro-Beryllium. (Ueber die Bestimmung des Berylliums in hochlegierten Stählen und Ferroberyllium.) HORST ECKSTEIN. *Zeitschrift für analytische Chemie,* Vol. 87, No. 7/8, 1932, pages 268-285.

The determination of Be in ores is briefly discussed and it is explained how analyses by weight can be advantageously supplemented by spectrum analytical methods. For determination in steels the oxine-, alkali-hydroxide-, acetate-, tannin- and ammonium sulphide methods are described which all give good agreement and accuracy with consideration of other alloying components. Ha (14)

The Effect of Manganese and Aluminum Content of Steel on the Determination of Oxygen, Nitrogen and Hydrogen according to the Hot Extraction Method. (Ueber den Einfluss des Mangan- und Aluminiumgehaltes von Stahl auf die Sauerstoff-, Stickstoff- und Wasserstoff-Bestimmung nach dem Heissextraktionsverfahren.) W. EILENDER & H. DIERGARTEN. *Mitteilungen aus den Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen,* Vol. 11, 1932, 5 pages.

See *Metals & Alloys,* Vol. 2, Dec. 1931, page 315. Ha (14)

Testing Precious Metals with the Touchstone. I, II, III. C. M. HOKE. *Brass World,* Vol. 28, May 1932, pages 92-93; June 1932, pages 112-114; Aug. 1932, pages 159-160.

The first installment outlines the old methods of testing alloys for Au and Ag. The second installment deals with Pt and its alloys. The old touchstone method is extended and developed to include Pt, Ir-Pt, Pd and its alloys, dental alloys and both kinds of white gold (Ni-Au and Pd-Au) as well as solutions containing these metals. Part III deals with the detection of Pd and Ni in white golds, Pt, or dental alloys. $Hg(CN)_2$ serves as a test for Pd, forming a dense precipitate from the milky solution. WHB (14)

A Method for the Determination of Slags in Low Carbon Iron and Steel. (Metod för elektrolytisk slaggbestämning i järn och stal med lag kolhalt.) RAGNAR TREJE & CARL BENEDICKS. *Jernkontorets Annaler,* Vol. 116, Apr. 1932, pages 166-196; Summary in *Iron & Coal Trades Review,* Vol. 125, July 1, 1932, page 3.

The electrolysis is carried out in a vessel with 2 compartments separated by a diaphragm. The Fe sample, surrounded by a collodion sack for holding the slag, is used as anode in a solution of 0.1 N KBr and 10% Na citrate, while sheet Cu, in 10% $CuSO_4$ solution, is used as the cathode. A current density is maintained so that the potential drop between the anode and the solution is less than 1.23 V. With these conditions evolution of H_2 and O_2 is prevented and the MnO is attacked less by the electrolyte than by distilled H_2O. The liberated slag can be measured by centrifuging, but a machine driven centrifuge is necessary. Microscopic examination may also be used for identification of the slag particles. The authors have thus identified small octahedral crystals of Al spinelle for the first time in Armco Fe. Chemical analysis of the slag shows some metallic Fe. Colloidal SiO_2 produces a large increase in the slag volume. The composition of the slags run approximately 36% Al_2O_3; 62% FeO and 1.2% MnO for Armco Fe; and 3.9% Al_2O_3, 93.3% FeO and 2.8% SiO_2 for Lancashire Fe. In Si steels the slag is 40-75% SiO_2 and the remainder Al_2O_3. The oxygen contents calculated from the slag analysis correspond closely to those found by vacuum extraction. Work is in progress on a method for high C steels. Ha + HCD (14)

The Determination of Sulphur in Steel. (Über die Bestimmung von Schwefel in Stahl.) *Die Metallbörse,* Vol. 22, Apr. 20, 1932, page 499.

The most important methods are listed in the introduction and special attention is paid to the combustion method in O_2 according to Holthaus recently improved by Guedras, who burns S at 1200° C. and passes the combustion gases into NaOH. Na_2SO_4 is formed and the balance of NaOH is titrated. EF (14)

Sampling of Ores and Other Metallurgical Materials Containing Metal as Well as Metals and Alloys. (Probenahme von Erzen und anderen metallhaltigen Verhüttungsmaterialien sowie von Metallen und Legierungen.) Selbstverlag der gesellschaft deutscher Metallhütten- und Bergleute, Berlin 1931. Paper, 5¾ x 8¼ inches, 108 pages. Price 4 RM.

This booklet, issued by the German Institute of Mining and Metallurgical Engineers, appears as a companion to the second edition of "Ausgewählten Methoden für Schiedsanalysen kontradiktorisches Arbeiten bei der Untersuchung von Erzen Metallen und sonstigen Hüttenprodukten." Sampling was included as a separate chapter in the first edition of the above work, but in the second edition it was omitted and appears in the present booklet.

Methods of sampling have been revised and changed in many instances in this edition. Suggestions from the industry have been utilized in making revisions.

The last 38 pages of the book have been devoted to the following subjects: Commercial tolerance of common impurities and additions, and the splitting limits for analytical samples of metallic residues and furnace products; German specifications for scrap, waste, and ingot metal; and American standard specifications for scrap metal.

There is no index. John D. Sullivan (14)-B-

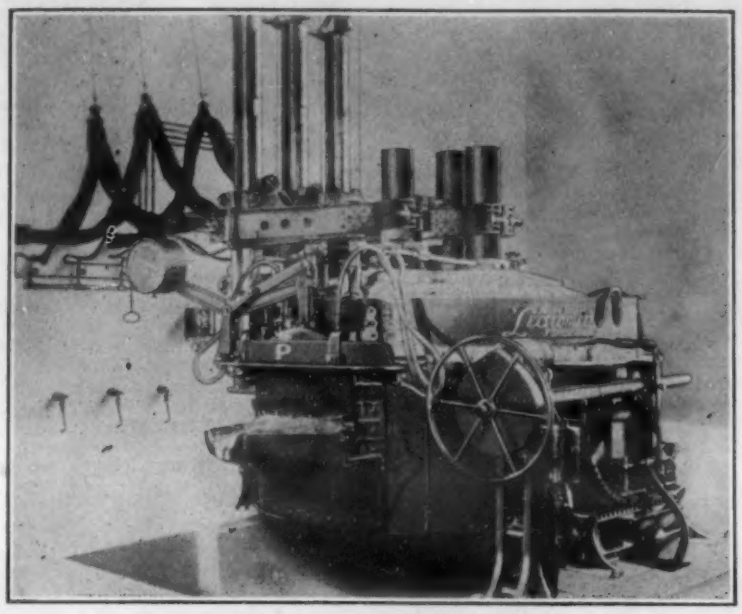
The Determination of Tungsten in High-Speed Steels as Tungstic Acid in the Gooch Crucible. (Die Bestimmung des Wolframs in Schnelldrehstählen als Wolframsäure im Goochtiegel.) H. WDOWISZEWSKI. *Zeitschrift für analytische Chemie,* Vol. 87, No. 1/2, 1932, pages 36-38.

A modification of the usual method is described by which the content of W is determined from chips of the steel as H_2WO_4 instead of as WO_3. The procedure is described in detail. Ha (14)

Electro-Analytical Determination of Gallium. (Die elektroanalytische Bestimmung des Galliums.) ERICH REICHEL. *Zeitschrift für analytische Chemie,* Vol. 87, No. 9/10, 1932, pages 321-332.

Metallic Ga was deposited on Pt-Ir cathodes from a sulphate solution with the addition of NaOH. The Ga potential is about 0.6 volts; it was found that a bright, firmly adhering metal was obtained when the electrolyte was stirred, while without this, a loose, dark gray deposit was obtained. The temperature seems to have an influence on the H-voltage; the time of deposition is shorter at higher temperatures. The method and procedure to be observed are discussed in detail. Ha (14)

The Analysis of Bronze and Brass. (Die Analyse von Rotguss und Messing.) O. NIEZOLDI. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 12, 1932, page 246; June 26, 1932, page 268.



Determination of Pb, Fe, Al. Ni, S, Cu, Sn, Zn in brass and bronze. GN (14)

Detection of Traces of Mercury by an Electro-chemical Method. (Elektrochemischer Nachweis kleinster Quecksilbermengen.) E. SCHMIDT & E. TORNOW. *Chemiker-Zeitung,* Vol. 56, Mar. 5, 1932, pages 187-188; Mar. 12, 1932, pages 206-207.

The test can be made in the presence of other metals and organic matter without previous separation. A graphite stick or carbon for an arc lamp is used as an anode and the cathode consists of a strip of Al .2 mm. thick. The solution is electrolyzed at 4 volts for 30 minutes. If Hg is present in the solution it acts as a catalyst and starts a reaction forming Al amalgam. The Hg goes back into solution leaving an oxidized area on the Al strip which is dull and can easily be distinguished from the bright metallic Al. When heavy metals are present the test is best made in H_2SO_4 solution and with the addition of some NaCl. To prove the effectiveness of the method tests were made with $HgCl_2$ and HgI_2 solutions containing $AgNO_3$, Na_3AsO_3, Na_3AsO_4, $CuSO_4$, $CdCl_2$ and other salts. The time required depends on the amount of Hg present and is longer in the presence of organic matter. The smallest amount of Hg detected in a pure NaCl solution was .001 mg. Quantitative determinations are not possible but the amount can be approximated from the size of the oxidized area, the current and the time. CEM (14)

The Place of the Emission Spectrum Analysis in the Metal Industry. (Die Rolle der Emissionsspektralanalyse in der Metallindustrie.) G. SCHEIBE. *Mitteilungen aus den Forschungsanstalten des GHH-Konzerns,* Vol. 1, July 1931, pages 123-127.

The possibilities of using the emission spectrum analysis, that is, the detection of elements in a mixture or a compound by means of the optical spectra except X-ray spectra, are reviewed. Qualitative and quantitative determinations can be made. The particular advantages of this method are its very great sensitivity, in many cases 0.001%, the very small amount of material required, the fact that elements which give difficulty in chemical analysis do not disturb the spectrum analysis, and the speed and cheapness of the method. For very small percentages the method is superior to chemical analysis in quantitative determinations. Flames or sparks are used to excite the spectra; the respective methods and apparatus are described. A small spectrograph with ordinary glass lens system permits the determination of the following elements and their lowest amount in %: Cr 0.01, V 0.1, W 0.8, Mn 0.05, Ni 0.2, Mo 0.2, Si 0.2. A quartz spectrograph is still more sensitive. The Fe spectrum and those of Si, P, B and Cu can be determined to a few hundredths of a percent. The precautions to observe when fixing the spectrum photographically are explained and a photograph is reproduced. 10 references. Ha (14)

Modern Lectromelt Tool and Stainless Steel Furnace of the Door Charge Type.

LECTROMELT Furnaces are also furnished in the Patent Swing Roof-Quick Top Charge Type for Drop Bottom Bucket Loading.

Users include many of the Leading Heat and Corrosion Resistant Alloy Manufacturers . . . Their operations are marked by

LOW OPERATING COSTS
HIGH QUALITY OF PRODUCTS
and
EXACT CONTROL OF CARBON AND ALL ALLOYS

A large number of Lectromelt Furnaces are also used for Plain and Alloy Irons such as cam shafts, brake drums, cylinder blocks, pistons and piston rings, abrasive irons, etc. . . . For limited outputs Lectrosimplex single phase furnaces are also manufactured.

PITTSBURGH LECTROMELT FURNACE CORPORATION
P. O. BOX 1125, PITTSBURGH, PA.

FOUNDRY PRACTICE & APPLIANCES (22)

Steel Foundry Practice in a Jobbing Foundry. C. D. POLLARD. *Foundry Trade Journal,* Vol. 46, Apr. 28, 1932, pages 264-267.

1 This paper deals with the production of steel castings in a jobbing foundry where castings from 50-60 lb. to 20 tons and upwards are being handled consistently. Considerable attention is directed to the problems of venting, of the bracketing of castings, of the placing of runners, and of the heading and feeding of steel castings. Attention is paid briefly to the question of sand, and the article closes with a discussion of the annealing, heat treatment, and welding of castings, together with a short reference to schemes for controlling output and deliveries. OWE (22)

Should Molds be Weighted or Clamped? (Formen verklammern oder Formen belasten?) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, June 12, 1932, pages 237-239.

2 The advantages and disadvantages of both of the methods are discussed. Which one is better fit must be decided from case to case. Various methods of clamping molds are illustrated and discussed. GN (22)

Electric Furnace Iron for the Foundry. N. L. TURNER. *Iron & Steel of Canada,* Vol. 15, July 1932, pages 77-78.

3 This article may be considered an addendum to a paper presented before the American Foundrymen's Association in Cleveland in 1930, in which furnace practice and costs of operation of a 3-ton electric furnace at the Beach Foundry in Ottawa, Canada, are described. Since 1930 the cost of producing Fe in this electric furnace has been still further reduced, and it has been shown that the furnace is still more flexible in operation than was supposed in 1930. The author gives a table with details of the cost of operating the electric furnace for one month, quoting the figure $19.88 as the total cost of operation per ton of Fe. The article is also accompanied by 2 photographs. OWE (22)

Remarkable Points in Constructing Drying Ovens. (Beachtenswerte Punkte bei der Anlage von Trockenkammern.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 21, 1932, pages 326-328.

4 Practical hints are given to be borne in mind in building ovens for drying molds. The arrangement of the heating contrivances and the use of cars for drying molds is particularly dealt with. GN (22)

Italian Steel Foundry Practice. GUIDO VANZETTI. *Foundry Trade Journal,* Vol. 46, Apr. 21, 1932, pages 248-249; Apr. 28, 1932, pages 257-259.

5 The author, after dealing with the history of the steel industry in Italy, discusses the present available plants in that country and the importance of the electric furnace to the Italian steel manufacturer. A comparison is made between the Bessemer converter and the electric furnace, and attention is directed also to the position of the open hearth in the steel foundry. The author expresses his preference for the electric furnace and then deals with the choice of electric furnaces for the type of work with which his paper is concerned. Considerable attention is directed to the question of the "castability" of electric steel. The paper closes with a description of the Vanzetti Foundry in Milan. OWE (22)

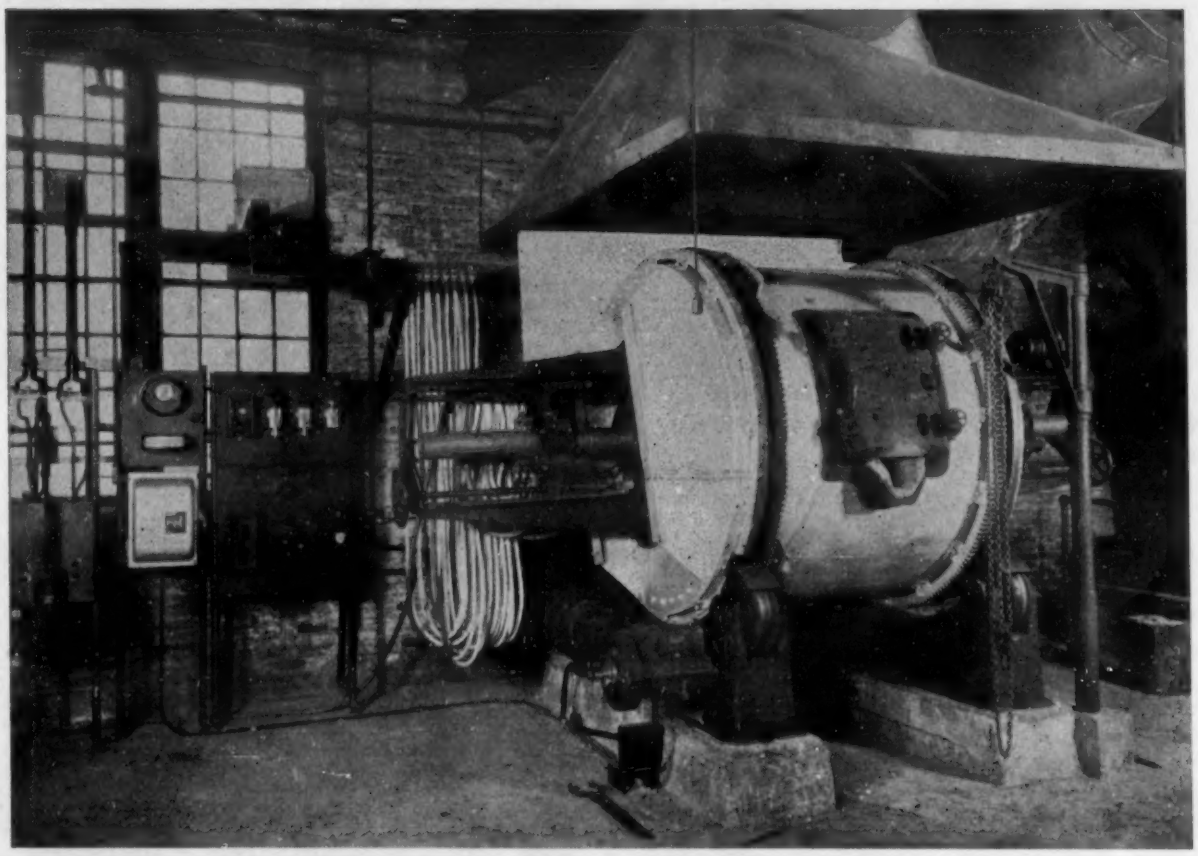
Charges for Heat Resisting Castings. (Gattierungen für wärme- und feuerbeständigen Guss.) *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, Aug. 7, 1932, page 306.

6 Abstract of a paper by Auguste Le Thomas in *La Fonte,* 1932, pages 75-95. The following compositions are given for various uses: For parts not to be machined white Fe with 2.6-3.3% C, .6-1.2% Si, .3-.5% Mn, .08-.12% S, P below .6%. The good heat resistivity of such an Fe can be still improved by higher Mn content (2-3%) or from .3-1.0% Cr. Heat resisting cast Fe which is to be machined contains 2.8-3.0% C, in cases up to 3.4% C, .8-1.3% Si according to wall thickness, .7-1.0% Mn, .05-.09% S and P below .3%. This Fe is suitable for thick-walled parts and for simple shapes. For thin-walled

7 and intricate parts which are easily machineable the following is suggested: 3.0-3.4% C, 1.3-1.6% Si, .7-1.0% Mn, .05-.09% S, P below .3%, .4-.8% Cr. Parts a few cm. in wall thickness are cast with 1.3% Si and .8% Cr, thinner parts with 1.5-1.6% Si and .4-.5% Cr. For obtaining high resistivity against heat, high mechanical strength, great structural uniformity and easy machinability the composition is advised: 2.8-3.2% C, 1.2-1.4% Si, .8-1.0% Mn, .05-.09% S, P below .3%, .5-.8% Cr and about 1.5% Ni. Fe of very high heat resistivity contains 1.5-2.0% Cr, about 13% Ni and 8% Cu. The composition of the corresponding charges is also stated. GN (22)

8 **Quantity Production of Grey-Iron Castings.** J. O'SULLIVAN. *Foundry Trade Journal,* Vol. 46, June 9, 1932, pages 350-353.

Paper presented at the Newcastle Meeting of the Institute of British Foundrymen, in which the Dagenham foundry recently opened by Messrs. Henry Ford and Son is the subject of complete discussion. OWE (22)



Introduction to the Study of Moulding and Casting. J. PILLON. *Foundry Trade Journal,* Vol. 46, June 23, 1932, pages 382-384; June 30, 1932, pages 400-404; Vol. 47, July 7, 1932, pages 7-10, 14.

9 The French exchange paper presented at the 29th Annual Convention of the Institute of British Foundrymen (June 7-10, 1932). The author introduces his paper by stating that these extracts from his lectures given at the Foundry High School in Paris are not intended for beginners but assume the possession by readers of a scientific training and a practical acquaintance with the art of molding and casting. The article is accompanied by 100 illustrations. The paper is divided into 2 sections—I. "Moulding and Metallurgy." In this the author discusses the investigation of the type of molding to adopt and deals fully with what he refers to as the parameters of molding. In this section attention is also directed to the method of using the pattern, to the investi-

10 gation of partings, and to a discussion of hand-molding as a function of the system of partings. Methods that may be used for simplifying castings are dealt with briefly, and devices whereby rapid molding may be accomplished occupy some space in the article. II. "Static and Dynamic Forces Exerted by Molten Metal on Moulds and Cores. OWE (22)

DETROIT ROCKING ELECTRIC FURNACES

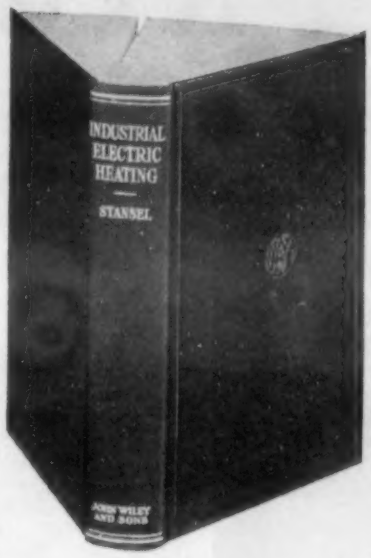
QUALITY CONTROL

SPEED ECONOMY

A Precision Melting Machine for Gray Iron, Alloy Iron, Malleable and Stainless Steels or Alloy Steel

These furnaces are used by many prominent concerns in the production of high quality castings, showing absolute control of analysis, high economy and excellent uniformity.

The rocking action of these furnaces permits the utilization of charges of 100 per cent borings in the production of castings of the highest quality at an extremely low cost per ton.



As a duplexing medium they are unequalled.

ANNOUNCING

INDUSTRIAL ELECTRIC HEATING

By

N. R. STANSEL

Associate Member A. I. E. E., Industrial Engineering Department — General Electric Company.

THIS book presents in concise form the more important principles of industrial heating and correlates with that presentation current practice in the industrial use of electric heat.

"Industrial Electric Heating" deals with the technical phase of electric-heat as the first step in its economical utilization. It is significant to the manufacturer as a new tool in which may be found the solutions of many manufacturing problems in which heat is a factor. The design of each type of electric furnace is presented as the introduction to its applications within the field for which it is designed. Typical applications of electric furnaces are described both to give some information regarding specific uses of electric-heat and to illustrate its diversification in manufacturing.

H. W. GILLETT,
Director of Battelle Memorial Institute says—

"The book is noteworthy for the things it doesn't waste space on and for the clarity and conciseness of what it does present. The author's long experience with the General Electric Company in the lines covered by the book has enabled him to treat his subject with authority. Besides being a highly informative volume, it is an extraordinarily good job of technical writing."

CONTENTS

Introductory; The Transfer of Heat; Heating and Cooling of Metals; Electric Heating; Heating Chambers; The Resistor Furnace; Atmosphere of Resistor Furnaces; Applications of the Resistor Furnace; Melting Metals; Melting Pots—Resistor Type; Arc Furnaces; Induction Furnaces; Supplement; Factors Affecting the Economics of Industrial Electric Heating; References.

444 pages—$5.00

FURNACES & FUELS (23)

Forging and Heating Furnaces with Long Distance Gas Supply. (Schmiede- und Wärmöfen mit Ferngasbeheizung.) H. REPKY. *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 13, Feb. 1932, pages 39-41.

1 The reasons for the higher capacities of remote gas fired furnaces are enumerated (2-3 times that for instance of oil fired furnaces): (1) A larger heat capacity can be attained in the hearth without reaching excessive temperatures and superheating the product to be heated. (2) the temperature is more uniform, the heat transfer is higher since a higher temperature difference between hearth and piece can be chosen. (3) the heat absorbing surface of the charge is larger. When the combustion properties of coke gas are taken into consideration sufficiently in the construction and arrangement of the burners, dimensions and form of the hearth, the gas down-take, and the operation of the furnace, coke gas is much better for the above-mentioned purposes and more economical than any other fuel. GN (23)

Some Future Fuel Problems in Metallurgical Practice. H. C. ARMSTRONG. *Proceedings 3rd International Conference on Bituminous Coal,* Vol. 1, 1932, pages 652-656.

The problems are: (1) future use of high-S coal, (2) cleaning of fuel gas, (3) automatic thermostatic control, and (4) smoke elimination. See *Metals & Alloys,* Vol. 3, Apr. 1932, page MA 110. AHE (23)

3 **American Gas Practice. Volume I. Production of Manufactured Gas.** JEROME J. MORGAN. Published by the author, Maplewood, N. J., 1931. Cloth, 6¼ x 9¼ inches, 969 pages. Price $8.00.

This is the first of 2 volumes, which result from material prepared for a home study course in manufactured gas for gas company employees, which has been sponsored jointly by Columbia University and the American Gas Association since 1925. The author has received coöperation from a committee of leading engineers in the gas industry.

4 This volume covers the many processes for the production of fuel gas, taking into account the fundamentals of the processes and the technique of operating the equipment, and goes thoroughly into the details and fine points of commercial practice. The literature is referred to extensively for specific illustrations and operating data. The book is well illustrated with cuts of equipment which is in current use in the industry, often in duplication to include the units by various manufacturers.

5 Related and minor topics which are fully covered include the history, physics and chemistry of gas; occurrence and production of natural gas; heating of gas making apparatus; coal and its relation to coal gas; carbonization processes and equipment; gas works refractories; conveying, crushing and screening equipment; boiler plants, fuels and feed waters; condensing, exhausting and scrubbing; purification; liquefied petroleum gases; reforming of hydrocarbon gases; and gas conditioning.

The book is authoritative and up to date. Liberal use is made of reliable data from the literature and a good bibliography is appended to each chapter. It is a worth-while reference text. The last chapter, "Developments and Future Problems," gives a summary of the growth and development of the industry and an insight into its probable trend for the next few years. F. B. Hobart (23) **-B-**

6 **A Review of Certain Gas Producer Practice.** VICTOR WINDETT. *Year Book of the American Iron & Steel Institute,* 1931, pages 218-293. See *Metals & Alloys,* Vol. 2, Oct. 1931, page 230. (23)

Conditions Determining Electrical Blast Furnace Gas-Purification Practice. (Die Massgebenden Einflüsse auf den Betrieb der elektrischen Hochofen Gas-Reinigung.) KURT GUTHMANN. *Stahl und Eisen,* Vol. 52, June 2, 1932, pages 529-539.

7 Report 127 of Blast Furnace Committee of Verein deutscher Eisenhüttenleute. Extended tests were made on 3 blast furnace units to determine the effect on the purification action of electrolytic filters of temperature, moisture content, CO_2 content of inlet gases, gas velocity, amount and chemical composition of blast furnace gas, precipitation voltage and condition of electrodes. The most important variable is the adjustment of the moisture content to the temperature of the gases at the inlet to the filter, and in this lies the task in the operation of an electrolytic filter. An operating curve, derived from numerous operating tests, permits a simple control and operation of the Dry-ElectroFilter system at both the Elba Huckingen and the SSW Oberscheld blast furnace units. Gas saturated with steam or water vapor gives best electrical purification, and herein lies the progress from the Dry to the Wet-ElectroFilter. A combination of the dry and wet methods is the so-called Lurgi 2-stage system, the major part of the removal being in the dry state. In addition there is the Lurgi-Electro-Wet Filter which gives good purification in 1 stage by the wet process. A complete tabular comparison is given of the 3 different methods for all factors entering into the purification process, including overall costs. 17 references, 18 graphs and illustrations. DTR (23)

Coke Oven Gas in the Iron and Steel Industry. H. LENT. *Gas Journal,* Vol. 198, June 1, 1932, pages 502-510.

9 The application of coke oven gas to the Fe and steel industry in Germany is discussed. The different types of furnaces used include: continuous tempering furnaces with automatic temperature regulation for wire and strips; large tunnel furnaces with extended combustion zone for making refractory bricks for ceramic and sheet industries, etc.; continuous enamelling furnaces; continuous re-heating furnaces for high-speed rolling mills; portable forge furnaces for drop forgings; plate and sheet annealing furnaces adapted from producer to coke-oven gas for the sheet industry; a forge furnace with external recuperator made of heat-resisting steel for the attainment of the highest possible efficiency; a semi-portable forging furnace; a half-ton tilting furnace with overhead burners for melting Al; pot annealing furnaces for cold-rolled materials; continuous wire furnaces for soft wires, no muffle being needed, the unprotected wires being exposed to the furnace atmosphere; furnaces for annealing and heat-treatment of welded tubes. Control Device for Combustion of Excess Gas in the Blast Furnace Hot Blast Stove. (Reglereinrichtung zur Verbrennung von Ueberschussgas im Hochofenwinderhitzen.) K. Theis. *Stahl und Eisen*, Vol. 52, June 9, 1932, page 563.
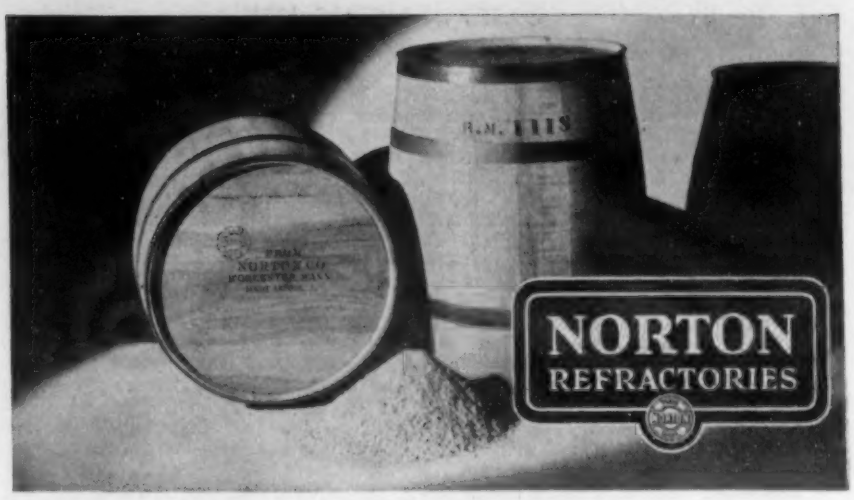
Fuel losses of 3 to 10% on hot blast stove and blast furnace gas-fired coke ovens may be eliminated by the use of an electrical regulating or control device to take care of any excess gas. A diagram of the hookup is shown for burning any excess gas in the hot blast stove. DTR (23)

Blending Coal for Coke Making. R. A. Mott & R. V. Wheeler. *Proceedings 3rd International Conference on Bituminous Coal*, Vol. 1, 1932, pages 587-606.
The initial contraction, initial expansion and final expansion temperatures and the % of such contraction and expansion are given for 18 English coals and compared with the mechanical strength index of oven coke from the same coal. The best coking coals are strongly swelling, inferior coking coals have low swelling power and non-coking coals are non-swelling. The coking of various sizes of coals and blends was studied using this test (4-6 g.), box tests (150-300 lbs.), experimental oven tests (500 lbs.) and large scale tests (10 tons). The addition of about 3% of fusain or 2.5% of coke breeze to coal increases the size and hardness of the resulting coke. AHE (23)

Improvement of Upper Silesian Blast Furnace Coke and Oxidation of Upper Silesian Coal. H. H. Koppers. *Gas World*, Vol. 97, Aug. 6, 1932, Coking Section, pages 10-14.
This abridged translation of thesis for degree of Dr.-Ing. at Technical College, Aix-la-Chapelle, Germany, describes experiments carried out on the production of coke for blast furnaces. See also *Metals & Alloys*, Vol. 4, Feb. 1933, page MA54. MAB (23)

Carbonizing Properties of Davis Bed Coal from Garrett County, Md., and of Mixtures with Pittsburgh Bed Coal. A. C. Fieldner, J. D. Davis, E. B. Kester, W. A. Selvig, D. A. Reynolds & F. W. Jung. *Technical Paper* 511, United States Bureau of Mines, 1932, 39 pages.
The Bureau of Mines method for determining the gas-, coke-, and by-product-making properties of coal at various carbonization temperatures from 500° to 1100° C. was applied to a low-volatile coal from the Davis or Upper Freeport bed, a high-volatile coal from the Pittsburgh bed and to 60:40 and 20:80% mixtures of these 2. The coke yields of the blends were in close agreement with the theoretical yields computed from the yields of the component coals and the proportion of these coals in the blends. AHE (23)



REFRACTORIES & FURNACE MATERIALS (24)

Distorted Magnesite Bricks. (Verdrückte Magnesitsteine.) K. A. Goslich. *Tonindustriezeitung*, Vol. 56, May 12, 1932, pages 511-512.
During burning the bricks are placed one on the other so that the lower layers are subjected to heavy loads; they crumple and then offer difficulties on lining furnaces, etc. The article describes the various reasons for this occurrence. Crumpling can be due to too high a content of fluxes (softening during burning and subsequently the danger of being crumpled is not so pronounced with bricks containing smaller amounts of fluxes) to an insufficient first burning so that the bricks do not sinter sufficiently, to an unfavorable grain size, to improper stamping while making the bricks. 3 references. GN (24)

The Expansion of Tschassow-Jar Fire Clay Bricks at High Temperatures. (Das Ausdehnungsverhalten von Tschassow-Jar Schamottesteinen bei hohen Temperaturen.) P. P. Budnikoff & W. Müller. *Berichte der deutschen keramischen Gesellschaft*, Vol. 13, Apr. 1932, pages 153-157.
Report from the Central Research Laboratory of the Ukrainian Refractory and Cement Trust. The investigation shows that the determination of the heat expansion of refractories is of value not only for judging the quality but conclusions can be drawn as to the origin of the raw materials of the refractories. The Tschassow-Jar clays investigated are used in Ukrainia for manufacturing refractory bricks for industrial furnaces. The expansion curves of a great variety of refractory bricks were taken at temperatures between room temperature and 1100° C. and are shown in diagrams. GN (24)

Zirconium Oxide and Its Use in Industry. (Das Zirkonoxyd und seine Verwendung in der Technik.) Hans Trapp. *Chemiker-Zeitung*, Vol. 56, Apr. 16, 1932, pages 306-307.
In nature ZrO_2 always occurs contaminated with hafnium oxide. Its melting point is about 3000° C., but has not been definitely determined. ZrO_2 has been used for high tension insulators. More scientific work is necessary to determine its melting point, thermal conductivity and electrical resistance. In regard to using it for firebrick its heavy weight when fired at 2000° and high cost must be considered. A new use for ZrO_2 is for melting crucibles CEM (24)

Sintering Dolomite with Gas. (Ueber das Dolomit-Sintern mit Gas, über die Gas feuerung von Schachtöfen und über das Verhalten von verschiedenen Dolomiten und von Kalk.) Nikolaus Kieffer. Doctor's thesis, Technische Hochschule Aachen. Mimeographed, 8 x 11½ inches, 49 pages.
Instead of calcining dolomite with coke, a shaft furnace was provided with a group of burners and a mixture of 70-90% blast furnace gas and 30-10% coke oven gas used as fuel. The method has been in successful use for 4 years. The design of the furnace and the arrangement of the burners are shown in drawings. Greater furnace output than with coke and a cost reduction of some 30% are claimed. Various grades of dolomite were studied in the laboratory. The German dolomite sintered at 1100° C. while a purer foreign dolomite required 1400° C. or above. The gas method is considered applicable to readily-sintering dolomites and to lime stone, but not so suitable for difficultly-sintering dolomites. The theory of burning of dolomite is discussed. HWG (24)

30 MELTS PER LINING

instead of 6 or 8 . . .

ACTUAL performance in the field is the best proof of the ability of Norton Magnesia Cements to render exceptional service. The following quotation is from a letter recently received:

"Relative to the results we have had in making linings for our small induction furnace from your RM 1118 Magnesia Cement, we can state that we have had so much success with it that an order for further material is going out in a few days.

"With the crucibles that we were using we seldom got more than six or eight melts per crucible. We have obtained more than thirty melts with a lining of your material and it is by no means done yet."

If you are using induction furnaces for the melting of ferrous or non-ferrous metals it will really pay you to give Norton Magnesia Cements a trial.

GASES IN METALS (25)

Oxygen and Its Influence on the Properties of Steel. G. VEINBERG. The Scientific-Chemical-Technical Institution, Leningrad, 1930. Cloth, 6¾ x 7½ inches, 275 pages. Price 5 roubles 50 kopeks.

This book appears to be a comprehensive and apparently an accurate critical review of the literature data on the subject as well as the author's observations. The author discusses different methods of oxygen determination, the oxygen content in Fe, steel and cast Fe and the effect of oxygen on the physical and mechanical properties of steel. Some of the conclusions drawn from the work of the author and references were as follows: 1. In a synthetic work one may use Armco Fe which contains 99.86-99.90% pure Fe, oxygen content varying from 0.020 to 0.092%. 2. In a precise work, it is better to use electrolytic iron, containing 99.99% pure Fe. (Abstractor's note: According to J. R. Cain, H. Schramm and H. H. Cleaves, "Preparation of Pure Iron and Iron-Carbon Alloys," *Journal Industrial & Engineering Chemistry*, 1916, page 217. Total amount of C, S, P, Mn, Si, Cu, Ni and Co in an electrolytic iron may be as low as 0.024%.) 3. Solid Fe may contain as much as 0.05% in a solid solution. (Abstractor's note: Presumably at room temperature.) The amount of oxygen which may be dissolved in liquid Fe at 1530° C. is 0.21%. In case the amount of oxygen present was above this limit (0.21%) there were 2 zones in the liquid metal and segregation of oxygen was pronounced. 4. Oxygen content of irons and steels have been shown in some cases to affect resistance of the metal to corrosion by air, sea water or 3% HCl solution. 5. The average amounts of oxygen present in pig and cast irons have been found as follows:

Coke pig Fe	0.022% O
Charcoal pig Fe	.023 " "
Cast Fe	.020 " "

6. Stainless 12½ Cr steel contained 0.012% O. 7. High speed, Ni and other special alloy steels may contain 0.007 to 0.014% O (probably as high as 0.022%). 8. Bessemer steel before deoxidation may contain up to 0.257% O and even more. On addition of spiegeleisen, O content may drop to 0.019%. The final O content varies in acid Bessemer steel from 0.006 to 0.018% and in basic Bessemer steel from 0.010 to 0.077%. 9. Thomas steel before deoxidation contains from 0.031 to 0.068%, whereas after deoxidation this content is 0.015 to 0.033%. 10. Acid open hearth steel contains a smaller amount of O than basic open hearth steel. With an increase in the content of C and certain other of the common impurities the amount of O decreases. For instance, with a total amount of impurities of 0.719% the O content was 0.034% and when the amount of impurities was 1.8% the O content was 0.021%. 11. Crucible steel contains 0.001 to 0.017% O. 12. In puddled Fe the O content may reach 0.603%. 13. In electric welding O is absorbed from the air and the O content in the weld metal is from 0.25 to 0.45%. 14. There is a difference between the O content of the bath of a molten metal and that of the solid castings produced. For example, the O content of the molten steel taken from the open hearth furnace was 0.025%, whereas O determined in rails was 0.021%. 15. There was observed a difference in the O content in molten metal before and immediately after pouring from the furnace into a casting. O is occluded from the air so that the ingot may contain 0.123%, whereas the liquid metal in the furnace contained only 0.0188% O. 16. O segregates but its segregation may proceed in the reverse order to the segregation of other impurities. 17. O lowers the melting point of Fe and steel. 18. Increase in O content may raise the temperature at which Charpy impact values reach a maximum. For instance with 0.086% O, the maximum Charpy value is obtained at 650° C., whereas with 0.23% O the maximum impact value is reached at 800° C. It is believed that the optimum forging and rolling temperature of Fe rich in O should be around 800° C. 19. O lowers the mechanical properties of Fe and steel. This is particularly true when the amount of O in low C steel reaches 0.05% or more. A. I. Krynitsky (25)-B-

Discontinuities in Adsorption Isotherms. ARTHUR F. BENTON & T. A. WHITE. *Journal American Chemical Society*, Vol. 53, Sept. 1931, pages 3301-3314.

In a study of the adsorption of gases by Ni, Cu and Fe, a considerable number of new examples of discontinuous isotherms have been found. The effects of temperature, poisons and heat treatment of the adsorbent on the discontinuities have been investigated. A new hypothesis of physical adsorption is proposed, according to which the observed steps represent the formation of concentric rows of adsorbed molecules, first at the edges of each crystal face, and building up successively toward the center. The hypothesis is shown to be supported by the known facts. The mechanism of adsorption in rows offers no difficulty if it is assumed that neighboring adsorbed molecules evaporate from the surface less readily than isolated molecules, and that physically adsorbed molecules posses mobility in the plane of the surface. MEH (25)

The Degasification of Cast Copper by Lithium. (Die Entgasung von Kupferguss durch Lithium.) A. BURKHARDT & G. SACHS. *Metallwirtschaft*, Vol. 11, Apr. 22, 1932, pages 239-242.

8 references. Cu cathode scrap was melted in graphite crucibles and small percentages of Li, P, Be, Ca, Si, Mg and Al were added shortly before pouring to deoxidize the metal. The electrical conductivity, density, tensile strength and elongation of the sand cast rods and conductivity of wire drawn from the rods were determined. All additions have a similar effect on the cast bars, small percentages improving all the properties. With bigger additions the conductivity is reduced while the other properties are not changed much. In wire form the conductivity is slightly increased by small additions and drops with bigger additions. Li is exceptional in its effect on the conductivity of both cast Cu and Cu wire. As little as .005 to .01% Li in Cu wire increases the conductivity 20% above that of the original material. Li and Be are especially suitable for deoxidizing Cu as an excess over the optimum amount is not harmful. With P an excess reduces the conductivity considerably and it should not be used. CEM (25)

The Effect of Pressure on the Liberation of Gases from Metals. (With Special Reference to Silver and Oxygen.) N. P. ALLEN. *Institute of Metals, Advance Copy* No. 604, Sept. 1932, 24 pages.

1 2 arrest points were observed in Ag melted in air. The second arrest was due to the liberation of O, as proved by visual observation during freezing. Ag melts containing various amounts of O were prepared by melting under several partial pressures of O. As the O content increased the higher arrest point was lowered while the lower one remained at a constant temperature, as in eutectiferous alloys. Ag containing O was frozen under pressure in an autoclave. As the pressure (of N or O) increased to 2 or 3 atmospheres the density of the ingots increased to a constant value. The significance of the results are discussed in some detail and a 3-dimensional diagram of the Ag-O system is presented. A method for eliminating blow holes in cast metals by solidifying under pressure is recommended. Melting Ag in contact 2 with O in a bomb proved that at sufficiently high pressures a Ag-Ag oxide eutectic similar in appearance to the Cu-Cu_2O eutectic is formed. The "internal gas pressure" in solidifying tough-pitch Cu was calculated from thermochemical data. This pressure was found to be about 92 atmospheres. JLG (25)

The Effect of the Treatment of the Melt on the Gas Content and Shrinkage of White and Gray Cast Iron. (Einfluss der Schmelzbehandlung auf den Gasgehalt und die Schwindung von weissem und grauem Gusseisen.) P. BARDENHEUER & 3 W. BOTTENBERG. *Die Giesserei*, Vol. 19, May 27, 1932, pages 201-206. INSPECTION (26)

Small High-Duty Pipe Testing Presses. *Hydraulik Review*, Vol. 2, No. 2, 1932, pages 9-11.

An automatic machine is described which tests in a routine way small pipes of about ⅜" diameter and from 4" to 20" in length by compressed air. Ha (26)

Applies Electric Gage to Continuous Inspection of Strips and Sheets. *Iron Age*, Vol. 129, Feb. 18, 1932, page 453. 4

Describes the application of the electro-limit gage made by Pratt & Whitney Co. for measuring the size of strip sheet, stock wire, foil, etc. The only electric power needed to operate the device is a 110 volt 60 cycle source. VSP (26)

Method of Copying the Profile of Rough Surfaces. (Eine Methode zur Darstellung der Profilkurven rauher Oberflächen.) G. SCHMALTZ. *Die Naturwissenschaften*, Vol. 29, Apr. 29, 1932, pages 315-316.

Deals with microscopic investigations of rough surfaces, for instance of machined metals, wood, paper, minerals, etc. 5 Due to a special illumination device arranged perpendicular to the inspected profile, the latter is illuminated through small slit. Under an acute angle a photograph can be taken and the entire surface can be tested by gradually shifting the illumination beam. EF (26)

Results of Tests Made in France on Long Distance Telephone Cables Recently Placed in Service. (Résultats Obtenus en France sur les Câbles Téléphoniques à Longue Distance Mis Récemment en Service.) J. REYVAL. *Revue Generale de l'Electricite*, Vol. 31, June 4, 1932, pages 775-779.

Gives the results obtained recently of tests made to measure 6 the effectiveness of cables by determining their quality. The kind of cable and the nature of the conditions to which they were exposed were taken into consideration. The cable tested was 80 kilometers long. The results are given in curves and tables. MAB (26)

Phonograph Pickup and Amplifier Used to Test Small Bearings. *Steel*, Vol. 90, Mar. 28, 1932, page 39.

A device for the rapid testing of small ball bearing assemblies. This consists of a 1/6 H.P. motor, a phonograph needle, a radio phonograph pickup, 2 stages of amplification, a standard loudspeaker and an indicating milliammeter. The 7 needle bears down on the outer race of the bearing as it rotates. Defective bearings are recognized at once by high-pitched noises and excessive currents in the loudspeaker circuit. JN (26)

Testing Method for Welded Constructions. (Prüfverfahren für geschweisste Konstruktionen.) H. SCHMUCKLER. *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, June 26, 1932, page 343.

A simple and inexpensive method for testing welds is described. By milling the weld seam and etching the quality can be studied. The apparatus, driven by an electric motor, 8 is equipped with a special type miller driven through a flexible shaft. The seam is not destroyed in the test. The apparatus has been adopted by the German Federal Railway. GN (26)

Inspection of Metals. (I) & (II). A. A. ROBERTSON. *Chemical Engineering & Mining Review*, Vol. 24, May 5, 1932, pages 267-273; June 6, 1932, pages 307-311.

A discussion of metallurgical testing. Inspection tests available are: (1) analysis, (2) mechanical tests, (3) non-destructive special tests, and (4) metallographic tests. Emphasis is given to the non-destructive tests. Metallographic 9 etching tests are classified as: deep etch, pickling etch, macro etch, and S-print. Various solutions employed for these tests are described. Tables indicate some hardness tests and hardness machines, metallographic etching tests, reagents for deep etching, and solutions for etching steel. WHB (26)

Photography of the Inside of Tubes. Detection of Defects. (Rohre werden innen photographiert. Materialfehler werden auf dem Film entdeckt.) K. L. WEBER. *Die Umschau*, Vol. 36, Jan. 16, 1932, pages 50-52.

A camera is described for taking snapshots of the inner 10 wall of tubes down to 7.5 cm. inside diameter. The various features of this inspection equipment, which operates entirely automatically, can be taken from several illustrations accompanying the paper. 8 photographs reveal the degree of machining and the defects of tubular bodies. Using a film a complete survey of the inside is secured. EF (26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Effect of Certain Alloying Elements on Structure and Hardness of Aluminum Bronze. SELMA F. HERMANN & FRANK T. SISCO. *Transactions of the American Institute of Mining & Metallurgical Engineers,* Vol. 93, 1931, pages 262-283.

The Influence of Phosphorus on Copper-Tin Bronzes. (Die Kupfer-Zinnbronzen und deren Beeinflussung durch Phosphor.) G. KREBS. *Zeitschrift für die gesamte Giessereipraxis,* Vol. 53, July 10, 1932, pages 281-282.

Discussion of the mechanical properties of bronzes and the effect of various contents of P on the properties. The tensile strength and toughness is nearly double that of common bronze. The good corrosion resistant properties of P bronzes are pointed out. GN (27)

Addition of Vanadium Improves Properties of Medium Manganese Steel. W. C. HAMILTON. *Iron Age,* Vol. 129, Mar. 3, 1932, pages 546-548.

Intermediate Mn steel often shows decided segregation, and if Mn is excessive, this segregation results in formation of martensite when steel is cooled rapidly in air. It is important to maintain proper ratio between C and Mn in order to obtain uniformity in microstructure and therefore uniformity in physical results. Another undesirable factor is due to tendency for excessive grain growth. Addition of about 0.10% V to this intermediate Mn steel produces marked improvement in microstructure and physical properties. Grain growth is retarded and V addition makes possible a different ratio between C and Mn which results in a steel with superior physical properties and without segregation. With same normalizing treatment the structure of the Mn-V steel is sorbitic rather than pearlitic. This steel is known as Hylastic V steel by the American Steel Foundries. VSP (27)

Precipitation Hardening of Steels with 18% Cr and 8% Ni Through Addition of Beryllium, Boron or Titanium and Their Effect on the Corrosion Resistance. (Ausscheidungshärtung der Stähle mit 18% Cr und 8% Ni durch Zusatz von Beryllium, Bor oder Titan und Ihr Einfluss auf die Korrosions-beständigkeit.) HUBERT BENNEK & PAUL SCHAFMEISTER. *Archiv für das Eisenhüttenwesen,* Vol. 5, June 1932, pages 615-620.

The uniform austenitic structure of 18% Cr-8% Ni steel was changed by additions of Be, Ti, or B, in amounts sufficient to cause hardening. The basic structure of the hardened alloys may be that of ferrite or austenite, or a mixture of both, depending on the alloying elements. In addition precipitating compounds and, at times, the compounds existing in the quenched condition, make their appearance. The remarkable change in hardening temperature of Be steel containing varying amounts of Ni may be explained by the appearance of 2 hardening reactions or processes, the α- and γ-solid solutions enabling these processes to take place. As a result of inappreciable stability of the α-solid solution, the hardening process begins even after short annealing at a rather low temperature (500° C.), while the more stable austenite requires increased annealing temperature (700° C.) or a longer tempering period at 500° C. The rise in hardening of austenitic alloys apparently follows a hardening process, which itself results only after a decomposition of the austenite into α-Fe. The high toughness of corrosion-resistant Cr-Ni-steel is considerably decreased by addition of Be, B, or Ti, even in the tempered or improved condition. In the completely hardened state these steels may be said to be even very brittle. Therefore the best suited temper for practical purposes is one giving an average amount of hardness. Furthermore, the good corrosion-resistance of pure Cr-Ni-steel is not attained with the alloyed hardened steels. 15 diagrams and 2 tables of test data on mechanical properties and corrosion resistance. DTR (27)

The Effect of Different Elements on the Annealing and Grain-Growth Characteristics of Alpha Brass. MAURICE COOK & HERBERT J. MILLER. *Institute of Metals, Advance Copy* No. 609, Sept. 1932, 15 pages.

The brass contained 70% Cu, 30% Zn and varying amounts of the following materials: Fe, P, Mn, Al plus Ni and Al plus Si. Sheets 0.125" thick that had been cold rolled to a reduction of 50% were annealed for ½-hr. periods. The annealing characteristics were determined by diamond pyramid hardness values and grain counts. In 70-30 brass, as in most metals, smooth curves result when the hardness is plotted against the annealing temperature. In brass containing any of the added elements mentioned above the curve differed in that after the first marked decrease in hardness the rate of decrease in hardness became negligible and then reached the rate normal for pure brass. The grain size did not increase as rapidly in the special brasses as in the normal brass. Tensile strength values paralleled the hardness values. Added elements also increased the initial softening temperature of the brass. It is suggested that the peculiar shape of the softening curves may be due to precipitation phenomena. 10 references. Creep Tests on High Test Electric Cast Steel. (Untersuchung hochwertigen Elektrostahlgusses durch Dauerstandversuche.) *B B C Nachrichten*, Vol. 19, Jan./Feb. 1932, page 18.

A brief account of creep tests on 15 heats of electric cast steel, alloyed with Mn, Cr, Cr-Ni and Mo in the annealed state. The creep limit was determined according to the abbreviated Pomp method. At 400° and 500° C. the values of the creep limit vary widely in dependence on the alloying constituents, at 600° C. the values decreased so much for all of the steels that the differences due to the alloying components are practically within the limit of accuracy of the tests. Also in dependence on the temperature the creep limits of the various heats vary extensively, for instance, the heat proving best at 400° C. need not be the best at 600° C. and vice versa. The maximum values of creep limit within the series of 15 heats amounted to: 42,700 lbs./in.^{2} at 400° C. 18,500 lbs./in.^{2} at 500° C. and 5,700 lbs./in.^{2} at 600° C. At high temperatures Mo alone offers good creep properties. Its effect can be still further increased by Cr and Cr-Ni. It was possible to improve the creep properties of a common straight carbon cast steel at temperatures of from 400° to 600° C. by 257%. The creep limit at a certain temperature is in a certain relation to the normal tensile strength. GN (29)

Tensile Properties of Steel Castings at Low Temperatures. (Festigkeitseigenschaften von Stahlguss bei Tiefen Temperaturen.) Richard Walle. *Stahl und Eisen*, Vol. 52, May 19, 1932, pages 489-490.

Mechanical properties of 2 cast steel samples are given for temperature range +20° to —77° C. Composition of materials tested:

	% C	% Si	% Mn	% P	% S
Stg 45.81	0.23	0.27	0.59	0.013	0.026
Stg 52.81	0.30	0.36	0.64	0.013	0.023

Methyl alcohol and CO_2 were used for low temperature work. Each sample was kept in cooling agent for 40 minutes until uniform cooling was obtained. For each property, 3 to 6 samples were examined, in order to take care of segregation in material, pipes, blow holes, inclusions or other casting defects. Also in some cases even more samples were tested to make certain of the data. The % changes in mechanical properties referred to properties at + 20° C. as unity are given in the table.

Temperature ° C	Upper elastic limit %	Tensile Strength %	Elongation %	Reduction of area %	Notch toughness %
		Stg 45.81			
—20	+ 6.25	+ 7.67	+ 3.28	— 3.84	—26
—60	+19.6	+16.7	+11.5	+11.0	—86
—77	+31.3	+21.2	+23.6	+ 7.68	—92
		Stg 52.81			
—20	+ 3.69	+ 7.55	— 6.38	— 2.7	—35
—60	+15.5	+15.3	—14.7	—22.6	—87
—77	+22.5	+19.9	—29.8	—38.9	—91

It is possible that the opposite behavior of elongation of the 2 cast irons may be due to preliminary heat or other treatment of the metals, although the structure was normal in both cases. Modulus of elasticity for both were equally high and independent of temperature. For notch toughness test a 10 mkg. hammer was used. The notch strength increased rapidly from +20° to —60° C., while below —60° C. the decrease was rather small. At —20° C. for Stg 45.81 it amounted to 5.7 mkg./cm.^{2}, and for Stg 52.81, 4.4mkg./cm.^{2}. DTR (29)

The Tensile Properties of High Quality Steels at Elevated Temperature. (Die Festigkeitseigenschaften hochwertiger Stähle bei Höherer Temperatur.) *Stahlbautechnik*, Supplement to *Montanistische Rundschau*, Vol. 25, July 16, 1932, page 8.

Abstract of a paper in "Mitteilungen der Städtischen Prüfungsanstalt für Baustoffe des Wiener Magistrats," No. 1, 1932. The first part of the paper is given to theoretical considerations on the effect of various alloying elements on the critical temperature limit in creep tests. In the temperature range below this critical temperature every element which does not combine with the matrix but which, due to its presence, hinders the capacity for slip of the crystals, will increase the creep limit. Elements which increase the amount of amorphous cement in the grain boundaries exert the same effect. In the temperature range above the critical temperature every element which increases the amorphous cement increases the creep limit. Elements which raise the strength of the amorphous cement also increase the creep limit. Ni refines the grain and thus increases the creep limit in the temperature range below the critical temperature. For the same reason Ni impairs the creep limit in the temperature range above the critical temperature, Cr, W, V and Mn which favor the formation of carbides increase the creep limit in both temperature ranges since they hinder the flow of material. The following table gives some of the results:

Material	Testing Temperature					
C steel						
Tensile Strength lbs./in.^{2}	20°C. 92450	400°C. 85300	500°C. 61200	600°C. 39800	700°C. 19900	820°C. ....
Proportional Limit lbs./in.^{2}	49800	15600	11400	5000	4300	....
Cr-Ni steel						
Tensile Strength lbs./in.^{2}	76800	.....	56900	31300	14200	7100
Proportional Limit lbs./in.^{2}	37000	.....	19900	12800	3600	1420
Elongation %	38	.....	25	32	52	70

GN (29)

Creep Testing of Carbon and Low Alloy Steels by the Short-time Methods. (Dauerstandfestigkeits Untersuchungen an Kohlenstoff- und niedriglegierten Stählen nach dem Abkürzungsverfahren.) Anton Pomp & Willy Höger. *Mitteilungen Kaiser-Wilhelm Institut für Eisenforschung*, Vol. 14, Report 199, 1932, pages 37-57.

This paper treats of the gradual "creep" of metals under long continued static load. The term "static endurance" seems suitable for use to distinguish the phenomenon from endurance under repeated stress. The first part of the paper is devoted to a thorough search and discussion of the literature. Applicability of a short-time or accelerated method for determining static endurance strength bears considerable weight on the question debated throughout the literature as to the existence of a true value for static endurance strength (creep limit). In this work Pomp and Enders' test method was used with several modifications. The magnitude and time of the initial load as well as the preliminary heating period before start of the test bear considerable weight on the test results. The tests were made on 10 C-steels, 4 low alloy-steels and 1 Cr-Ni-steel, in the form of 20 mm. boiler sheets, 15x30 mm. open hearth steel bars, 18 and 25 mm. diam. low Ni, low Mo, low Mo-Cu, low Cr-Mo steel rods. The values obtained were compared with the elastic limits by the ordinary breaking or rupture test, and an approximately constant ratio was established between the 2 values for C-steels. This ratio varied with temperature. Static loading endurance tests up to 840 hours showed that a rate of elongation of $1x10^{-4}$%/hr. would be exceeded with loadings somewhat lower than the static endurance strength, as determined by Pomp and Enders' short-time method. Thus it appears that this accelerated method is practically confirmed for C— and low alloy steels. However, for a Cr-Ni-steel this method is not applicable. The rates of elongation, occurring with loadings in the range of the static endurance strength, for 3 to 6 and 25 to 35 hour periods, check closely with Pomp and Enders' data. On the basis of static endurance tests it may be said that the increase of the total residual elongation between the 40-hour period and the time for reaching the rate of elongation $1x10^{-4}$%/hr., a rate that practically may be disregarded, amounts to not more than 0.15%. DTR (29)

X-Ray Studies of the Thermal Expansion of Bismuth Single Crystals. Alexander Goetz & Rudolf C. Hergenrother. *Physical Review*, Vol. 40, May 1932, pages 643-661.

Previous observations of several investigators have shown certain anomalies of Bi at high temperatures of which the thermal expansion is very prominent. In order to decide whether those effects are to be ascribed to changes in the crystal lattice or in the mosaic structure, the "temperature shift of Bragg reflections" has been studied quantitatively between liquid air temperature and the melting point of the metal. A modified Siegbahn method, previously described by Hergenrother, has been used and an arrangement is described which allows the crystal to be maintained during the observation at liquid air temperature, or at any temperature between 20° and 265° C. The shift of Mo $K\alpha$ radiation reflected from the (111) plane of a Bi crystal has been measured for the first to the fifth order at twelve different temperatures and from it α_{II}, the thermal expansion of the crystal along (111), was calculated. These results have been compared with the values of the true specific heat of Bi and a surprisingly high degree of constancy of α/c_p has been found up to a few degrees below the melting point. Between room temperature and the melting point the thermal expansion coefficient is given by:

$$\alpha_{II} = 14.4 \times 10^{-6} [1 + 1.76 \times 10^{-3} (T_{abs} - 298°)]$$

whereas:

$$c_p = 2.84 \times 10^{-2} [1 + 1.76 \times 10^{-3} (T_{abs} - 323°)]$$

The values of the thermal lattice expansion thus obtained are compared with measurements of α_{II} obtained in the usual macroscopic way by several investigators and also with values observed on the same crystal in the laboratories of the authors. The macroscopic values are found to be different from the X-ray values many times more than could possibly be explained by experimental errors, the principal discrepancies being first a much larger value of $d\alpha/dT$ for the lattice expansion, second the absence of a gradual reversible decline of $d\alpha/dT$ at higher temperatures, which decline is typical for the macroscopic crystal. The X-ray shift does not show any indication of a discontinuity in the expansion within the temperature range observed. Hence the allotropic transformation at 75° C. and close to the melting point do not exist in the sense of a change of the lattice spacing. A definite discontinuity has been found however in the macroscopic expansion at 75° C. This must be ascribed to a small but sudden change in a periodicity of a larger parameter than the X-ray wave-lengths. WAT(29)

On the Influence of Temperature on the Elastic Behaviour of Various Wrought Light Metal Alloys. Franz Bollenrath. *Journal Institute of Metals*, Vol. 48, 1932, pages 255-272.

Chrome-Tungsten Steel for High Temperature. V. T. Malcolm. *Iron Age*, Vol. 129, Feb. 4, 1932, page 331.

From a paper read before the Hartford section of the American Society for Steel Treating. Ideal alloy steel for high temperature service would show complete resistance to abrasion, corrosion and oxidation. Minimum requirement of steel for such use is the ability to carry loads continuously without appreciable distortion. C steels are not suitable for temperatures over 700° F. Ni-Cr steels may be used up to 900° F.; 18% Cr steels show grain growth above 900° F.; 18 and 8 rustless steels develop intercrystalline brittleness between 900° and 1200° F. Recommends Cr-W for such service. Cr and W strengthen steel below equi-cohesive temperature, assist the work of C and reduce amount of occluded gas, giving finer and denser structure. VSP (29)

Strength of Materials Subjected to Shear at High Temperatures. FRANKLIN L. EVERETT. *Transactions American Society of Mechanical Engineers,* Vol. 53, 1931, Applied Mechanics, pages 117-134.

The problem of the creep of materials is treated from a new angle; torsion methods of investigating it are being employed instead of the usual tension methods. This method is said to offer greater accuracy in the measurements of creep and provides simplest stress conditions; a uniformly pure shear is produced in a thin tubular specimen submitted to twisting while the usual method employs a solid bar in tension where the shear stress is more complicated. Tests were made at 400°, 450° and 500° C., after the normal physical properties of the test piece had been determined at room temperature. Another advantage of this method is that the effect of temperature fluctuations is negligible in the torsion test whereas the elongation by temperature is serious in the tensile test. The apparatus and methods used are described and the curves showing the relation of temperature-electricity modulus, temperature-ultimate strength and duration of test-shear strain are reproduced. Tube Failures in High Pressure Boilers. (Rohrzerstörungen an Hochdruckkesseln.) *Die Wärme,* Vol. 55, Feb. 27, 1932, pages 139-140.

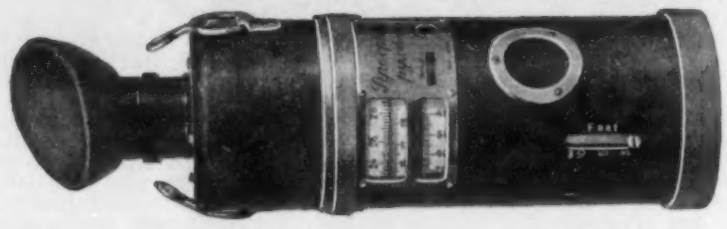
After one year service some tubes of a 40 atm. boiler failed in service while no corrosion was noticed on the same material incorporated in a 15 atm. boiler. The composition of the corrosion products pointed to an overheating of the tube walls resulting in a reaction between H_2 and Fe. EF (29)

Method for Measuring the Coefficient of Heat Conductivity of Metals. (Verfahren zum Messen der Wärmeleitzahl von Metallen.) E. RAISCH. *Forschung (Zeitschrift Technische Mechanik und Thermodynamik)* Vol. 3, July/Aug. 1932, pages 209-211.

An arrangement for the determination of the heat conductivity of metals, developed by the Forschungsheim für Wärmeschutz at München, is described. The method can be used for the temperature range up to 900° C. and metals of various heat conductivities. The accuracy amounts to ± 5%. The following results were obtained on low C steel and a Cr-Ni alloy.

Composition of the sample	Coefficient of heat conductivity in Kcal./m. hr. at a mean temperature of °C.								
	100	200	300	400	500	600	700	800	900
.12% C, .5% Mn, .12% Si, .05% S, P, Cr.	43.0	39.5	36.5	33.0	29.0	25.5	....	....	....
15% Cr. 61% Ni. 20% Fe, 4% Mn.	10.2	10.5	10.8	11.0	11.1	11.3	11.5	12.0	12.5



The values for the C steel at higher temperatures are somewhat lower than some of the data found in the literature. 3 references. GN (29)

The Behavior of Metals at Elevated Temperatures. (Das Verhalten von Metallen bei höheren Temperaturen.) H. STÄGER & H. ZSCHOKKE. *Schweizerische Technische Zeitschrift,* Vol. 29, June 2, 1932, pages 333-342; June 9, 1932, pages 345-354.

This is an extensive investigation on the creep limit of various materials carried out by the research laboratory of the Brown, Boveri Co. The first part of the paper is given to theoretical considerations on the behavior of crystal grains and grain boundaries at elevated temperatures, the effect of alloying elements on the creep limit, the behavior of austenitic steels, effects of heat treatment and structure and external influences, as oxidation. The machine used is described, the tests bars were heated in a salt bath, the extension was recorded automatically. The creep limit is defined as the load at which the velocity of extension of the test bar amounts to .001%/hr. between the 16-33 hr. of the test. The 2nd part of the paper reports the results. 8 cast steels of various composition were tested as received as well as annealed at 400°, 500° and 600° C. The results show that the effect of the various alloying elements is in accord with the theoretical considerations. In comparing the creep limits with short time tensile tests (yield point, tensile strength, elongation and notch toughness were simultaneously determined at room temperature, 400°, 500° and 600° C.) it is found that such tests do not permit drawing conclusions as to the creep limit. 14 steels were tested: Armco iron, straight C steels and alloy steels containing Ni, Cr, Ni-Cr, Cr-Mo, Cr-V, Ni-Cr-W, Cr-Mo-V, and Ni-Cr-Mo-V. These tests were also carried out at 400°, 500° and 600° C. It was found that the creep limit attained high values even at 600° C. but only in alloy steels, the C content of which does not exceed a certain rather low value. In exceeding this value the creep limit is impaired. A high Ni content is not favorable in spite of the austenitic structure. Welded joints were also tested, made by the fusion as well as the electric method. The creep limits were determined for the base steel plate, the weld and the welded joint. At 300° C. the creep limit of the joint is somewhat lower than that of the base plate, but higher than that of the welding material. At 400° C. the creep limit of the electrically welded joint corresponds to that of the base metal. The values of the fusion weld are lower. At 500° the creep limit of the base metal and joint are the same. There finally were determined the creep limits of soft and hard soldered joints. 5 various soft solders and 3 various hard solders were used to make the joints. The soft soldered joints were tested at 20°, 75° and 100° C.; the hard soldered joints at 150°, 200°, 250°, 300° and 350° C. It is stated that the melting point of the solder used is not of prime importance for the creep limit of such joints. GN (29)

PYRO THE SIMPLIFIED OPTICAL PYROMETER

SELF-CONTAINED, DIRECT READING, RUGGED AND FOOL PROOF

Unique construction enables operator to rapidly determine temperature even on minute spot or fast moving objects.

PYRO OPTICAL has proven its worth in the following industries:

Iron and Steel Foundries, Glass and Ceramic, Gas and Coke Oven, Refractory, Steel Casting, Rolling, Forging Plants, The Laboratory.

In fact, wherever heat above 1400° F. must be measured accurately and quickly.

Let us explain how PYRO OPTICAL can serve you, by keeping a close check on your heat control equipment—recorder or indicator type—for maximum efficiency.

Weight, complete, 3 lbs.

Stock Ranges: 1400° F. to 5500° F.

Bulletins on PYRO Radiation-Immersion-Surface Pyrometers and PYRO Super-Sensitive Radiation Tubes-Rapid Recorders on Request.

THE PYROMETER INSTRUMENT CO.

105 LAFAYETTE ST., NEW YORK, N. Y.

PITTSBURGH, PA. Grant Building

LOS ANGELES, CAL. 4920 Loma Vista Ave.

USE

IMPHY BILAMES

WHEN YOU NEED THERMOSTATIC METAL TO STAND UP UNDER ADVERSE CONDITIONS

THE low-expansion metal of these bimetallic strips is the genuine Invar made by Acieries d'Imphy for over 30 years. The high-expansion element is a special alloy having a high elastic limit, practically the same as that of the Invar. Due to a special final treatment these Bilames have a nearly perfect stability, the deformations by heat and cold being reversible after an indefinite number of cycles. Both metals are practically inoxidizable.

When of the proper dimensions they can be used for direct mechanical operation of many control devices. When used with electric current the two elements have, happily, a resistance of the same order, resulting in heating from the electric current as uniform as in a homogeneous conductor.

Two types are available—one for the range from —100° C. to +150° C., the other suitable for temperatures up to +300° or 400° C.

THE R. Y. FERNER COMPANY

INVESTMENT BLDG. WASHINGTON, D. C.

Elastic Limit at Elevated Temperatures and Creep Strength of Steel. (Warmstreckgrenze und Dauerstandfestigkeit des Stahles.) FRIEDRICH KÖRBER & ANTON POMP. *Stahl und Eisen*, Vol. 52, June 9, 1932, pages 553-559.

The determination of elastic limit under heat, the test method being carried out uniformly, particularly adhering to a definite and a sufficiently extended loading period, gives good check values. Up to temperatures at which testing period gives only slight deviations in results (for straight C steels 300°-350° C., for alloyed steels 350°-450° C.), the elastic limit under heat may be used as a suitable basis for a comparative study of materials and also for the estimation of allowable stresses. The ratio of high temperature yield point to tensile strength at room temperature, for straight C-steels lies within comparatively narrow limits. Thus it is possible to calculate with fair degree of accuracy high temperature yield points from tensile strength at room temperature. With alloyed steels a greater number of tests must first be made to derive the relation of yield point to tensile strength at room temperature, before the latter can be used to calculate yield points at various temperatures. With higher temperatures, due to the progressively increasing importance of the time factor on the elastic limit, more reserve and care must be exercised if the high temperature yield point determinations are to be used to explain the behavior of the material. Under continuous loading exceeding the temperature limits mentioned above, the creep strength only may be used as a measure of properties of the material. On account of the long testing periods requisite for determination of creep, short-time or rapid methods have been developed of late and these rapid methods depend on the determination of rate of elongation in a certain fixed time interval. The authors emphasize the fact that their data show that even slight differences in the short-time test conditions give considerable deviations in the results, and consequently that these short-time tests as developed at the present time are not yet suited or conclusive enough. Data is tabulated showing elastic limit of 2 C-steels and 1 Ni-steel at 20°, 200°, 300°, 350°, 400° and 450° C. Tests made on both 25 mm. round bars or rods and 40 mm.o.d. tubes, 5 mm. thick. Loads applied were maintained 30 sec. for each loading stage. 9 diagrams and 14 references. DTR (29)

Thermal Stresses in Thin-Walled Cylinders. CLARENCE H. KENT. *Transactions American Society of Mechanical Engineers*, Vol. 53, 1931, Applied Mechanics, pages 167-180.

The Determination of Time-Elongation Limits in the Creep Test. (Die Bestimmung von Zeit-Dehngrenzen im Dauerstandversuch.) E. SIEBEL & M. ULRICH. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, July 2, 1932, pages 659-663.

It has been found that the tensile properties of all metals are dependent under the influence of heat on the time. Even at low temperatures, the elongations due to a certain load do not take place immediately but require a few seconds; at higher temperatures, especially above 300° C., this time lag assumes greater proportions, and so the question arose for a standard in the evaluation of endurance test results and an abbreviated test method. On the strength of experiments it is suggested to use that load, as practical static endurance limit for elongation, at which the elongation velocity for 0.2% permanent elongation has dropped to 1×10^{-4}% per hour. The determination by test of this recommended time-elongation limit can be simplified if the time-elongation curve is assumed to be a parabola. It is then possible to determine, by extrapolation from time-elongation curves taken over at least 50 hours of testing, the elongation velocity for 0.2% permanent elongation. 22 references. Ha (29)

Extreme Temperature Metals. H. W. GILLETT. *Mechanical Engineering*, Vol. 54, Feb. 1932, pages 113-114.

A general survey of the present state as reflected in recent paper on the subject, with special regard to the symposium held in Chicago, June 1931. Alloyed steel, particularly those containing Mo and W, have recently been given preference with nitrided steels following. Ha (29)

Sintering Tests on Siderite Ore from the Helen Mine, Michipicoten, Ontario. T. W. HARDY & W. S. JENKINS. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 206-210.

1 A siderite ore assaying Fe 36.8 and S 1.34% sintered but owing to its very fusible nature precautions must be observed to prevent sticking to the pan. About 0.40% S was the lowest S value obtained. Precalcining does not improve either reaction. AHE (31)

Sintering and Sponge Iron Tests on Pyrite Residues. T. W. HARDY & W. S. JENKINS. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 202-206.

2 The residue from the Freeman process for utilizing pyrite in pulp and acid manufacturing, analyzing Fe 63.00, S 0.65 and insolubles 6.92%, gave a rather weak and brittle sinter, but suitable for blast furnace use. A metallization of 93.5% was secured using city gas. The magnetic concentrate assayed Fe 80.24, metallic Fe 76.20 and S 0.06%. AHE (31)

Innovations in the Roasting of Siderite in Siegerland. (Neuerungen in der Röstung des Spateisensteins im Siegerland.) WILHELM BLUM & HUBERT GLEICHMANN. *Stahl und Eisen*, Vol. 52, June 16, 1932, pages 582-587.

3 Data are summarized on roasting furnaces with amount of charge, charging time, blowing time, power and fuel consumption, furnace type and dimensions for 15 different units roasting siderite in the German Siegerland. The major economy and improvement in furnace performance and the resultant decrease in fuel consumption was obtained through substitution of forced and induced draft for natural draft, although this requires increased attention in the operation of the furnace. Lower labor costs will result only when complete mechanization has been perfected. Replacement of the scattered fire by indirect heating, which is generally regarded as advantageous, is still in the experimental stage in the Siegerland. Difficulties are met in working up the fine material. Special furnaces are used for roasting the fines in order to get satisfactory results. DTR (31)

Blast Furnace Practice in 1931. GEORGE B. GARRETT. *Blast Furnace & Steel Plant*, Vol. 20, Jan. 1932, pages 54-55.

Operators have been faced with the problem of producing the least possible tonnage on a given furnace and of disposing of surplus gas while keeping cost of production low. Large furnaces are being run at ⅓ to ½ rated capacity by using a constant reduced blast, by carrying full wind for intermittent periods, interspersed with periods when only a few lb. pressure with relatively high blast temperature is
5 carried; by blowing the furnace to capacity during the day and "fanning" during the night; and by banking over the week-end or other periods. Interesting results have been obtained with furnaces running on a burden of 70-100% sinter. Flue dust losses have been reduced by increased diameter of throat and large bell, together with larger downcomer outlet connections. Disintegrators are still favored for final cleaning of gas. An electrical precipitation unit for cleaning gas has been installed during the year. Small, well insulated checker stoves, of high efficiency are being installed. Much attention is being paid to screening
6 of coke. MS (31)

The Blast-Furnace. (Der Hochofen.) E. DIEPSCHLAG. Otto Spamer Verlag, Lepzig, 1932. Paper 7 x 10 inches, 313 pages. Price 25 RM.

The author is professor of metallurgy at the Technical High School, Breslau. The treatise discusses the blast furnace from the point of view of the physical chemistry of everything that goes on inside the furnace.

7 It is perhaps written from a somewhat more academic standpoint than Johnson's monumental work published in 1918, but covers much the same ground and, of course, includes much important information not available 14 years ago.

It deals with such subjects as rate of reaction of coke and the various factors involved in the choice of coke, temperature distribution and gas composition within the furnace, the properties of various types of ores, the principles of combustion, problems pertaining to the blast, the sizing of the charge and the calculation of charging, the mechanism of reduction and carburization, the metallurgy of fur-
8 nace operation, behavior of Mn, Si, P and S, and how to produce pig of different kinds, fluxing, slag equilibria and the principles of blast furnace construction and of maintenance of refractories.

A good deal of operating data is given to bring out various points in the discussion, but the treatment is along the line of general principles rather than specific cases.

While some attention is paid to foreign practice and to the work of investigators in other countries, German thought and practice is drawn upon primarily.

9 It is a useful book, one that blast furnace men will want on their shelves. H. W. Gillett (31)-B-

Modern Blast Furnace Operation. George W. Tobin. *Blast Furnace & Steel Plant,* Vol. 20, Mar. 1932, pages 257-258; May 1932, pages 420-421.

Deals with features of auxiliary equipment of large-hearth furnaces. Long, wide Fe trough, 22 ft. x 3.5 ft. x 2½ ft., allowing in depth and width for a rowlock lining of brick, has many advantages. Fe runners should be as short as ladle truck clearances will permit. Runner shutters should be large and lifted by means of a cable and counter-weight system from a central lever station. Slag runners should be straight and short, lined with coke braize and sand salvaged from Fe runners. Lining spout noses with clay increases life of castings. Crane in cast house makes possible use of overhead bins for sand and coke braize and a brick-lined pit sunk in the floor for a large clay box. Cast house floor-plan should allow adequate working space, facilitate short haulage of scrap and sand, and permit easy cleaning by sloping floor from runners to wall limits. Best in cast house construction is that which includes sliding side-wall partitions. Flooring should be of brick laid row-locked. Fe plates, with bottoms of cast-in fire-clay brick, and molded with a safety tread surface, should be used for runner crossovers. Basting with a light mixture of loam and water, while castings are hot, will protect mud-gun noses, skimmer gates, Fe runner gates, and upper sections of Fe and slag runners. Common rock-salt is invaluable in cutting down skulls, high bottoms in Fe ladles, and lengthening life of ladle lining. Furnace tools should be stored properly and inspected regularly. A completely automatic electric clay gun has been developed recently. MS (31)

Factors Controlling the Crystallization of the Graphite in Pig-Irons. Colin D. Abell. *Foundry Trade Journal,* Vol. 46, June 2, 1932, page 341.

The factors controlling the precipitation of graphite in molten pig-Fe are: (a) the critical temperature of the hearth of the furnace, (b) the amount of moisture in the blast, (c) the relative amount of graphite deposited in the shaft zones of the furnace and obtained in the Fe residues of the impregnated-coke phase, (d) the temperature of the core zones and the rate of driving the furnace, (e) the composition of the slag, and (f) the frequency of flushing the slag. The article is intended as an addition to that by Hanemann, abstracted in the *Foundry Trade Journal,* April 7, 1932, page 223. The following factors control the molecular orientation of the C in pig-Fe; the percentage Mn in the Fe, the percentage S in the Fe, the spinel content of the slag. OWE (31)

A Study of High-Manganese Slags in Relation to the Treatment of Low-Grade Manganiferous Ores. C. H. Herty, Jr., J. E. Conley & M. B. Royer. *United States Bureau of Mines, Technical Paper* 523, 1932, 36 pages.

No evidence has been obtained which indicates the possibility of obtaining fluid slags in the region above 60% MnO in the ternary system MnO-FeO-SiO_2 without the addition of some fluxing agent. Al_2O_3 and borax appear to be the most satisfactory fluxes for the high-MnO slags, Al_2O_3 being preferable because of economic reasons. Laboratory tests indicate that a satisfactory grade of ferro-Mn may be obtained at about 1550° C. from high MnO slags which have been fluxed with Al_2O_3. AHE (31)

Ferro-Manganese Plant Sestaphoni, Georgia. (Ferromanganwerk Sestaphoni, Georgia.) M. Kauchtschischwili. *Siemens-Zeitschrift,* Vol. 12, May 1932, pages 174-180.

A detailed description is given of a new plant in the Caucasus mountains where the native Mn ores are reduced to ferro-Mn in electric furnaces of 7500 kva. The world production of Mn is reviewed and the advantages of the electric over blast furnace production discussed. Metallurgical calculations of the reduction in the electric furnace are given and the heat balance made up. The consumption per ton of 80% Fe-Mn is about 3500 kwh. at a capacity of 40 t./24 hr. or 14,500 t. yearly. The current density is about 4.2 amp./cm.^{2}, voltage 110 volts; the C electrodes have a diameter of 1100 mm. and carry 40,000 amp.; the power factor is 0.8. Ha (31)

The Reduction of Magnetite and Limonite by Methane. (Die Reduktion von Magnetit und Limonit mit Methan.) Oskar Meyer & W. Eilender. *Mitteilungen aus dem Institut für Eisenhüttenkunde der Technischen Hochschule zu Aachen,* Vol. 11, 1932, 4 pages.

Causes of Dirty Spots in Enamel. (Ursachen von Schmutzpunkten in Emails.) H. J. Karmaus. *Sprechsaal für Glas, Keramik, Email,* Vol. 65, June 16, 1932, pages 340-341.

The paper discusses the various causes of impurities in enamels (1) in the raw materials, (2) in grinding, (3) furnace operation, (4) during enameling. 2 references. GN (32)

Fish Scale. (Fischschuppen.) L. Vielhaber. *Emailletechnische Monatsblätter,* Apr. 1932, pages 28-29.

Fish scale on enamels is not caused by admixtures of mica or quartz grains to the enamel but to effects of pressure, particularly gas pressure (hydrogen). It is evident that the pickling process plays an important role in avoiding fish scale. If, despite properly pickling, fish scale appears on the enamel it must be borne in mind that enamels tend to molecular stresses or crystallizations respectively so that pressure is set up. So-called "splash-proof" enamels are secured by the use of suitable feldspar and by a weak burning of the base enamel. GN (32)

Influence of the Chemical Composition on the Enameling Properties of Cast Iron. (Einfluss der chemischen Zusammensetzung auf die Emaillierbarkeit von Gusseisen.) P. Eyer. *Emailletechnische Monatsblätter,* Feb. 1932, page 14.

S is particularly detrimental to the enameling properties of cast Fe in that the segregations of iron sulphide and manganese sulphide render difficult the adherence of the enamel to the surface. The dangerous effect of S can be decreased by a sufficiently high amount of Mn. Too high an amount of P increases the brittleness so that the Fe tends to the formation of cracks on being enameled. The P content should not exceed 0.9%. The Si content should amount to at least 2.2%. With a Si content above 2.6% a coarse separation of graphite and an increased tendency to growing may be apparent. This also may be detrimental to enameling. GN (32)

Testing Pipe Line Coatings in Place. R. J. Kuhn. *Oil & Gas Journal,* Vol. 30, Apr. 21, 1932, page 47; *Gas Age-Record,* Vol. 69, May 7, 1932, pages 568-570, 582.

Paper before the American Gas Association Distribution Conference. The electrical resistance of the coating on a 2500 ft. section of 12" steel pipe at New Orleans, La. was measured in place when first laid and at various times up to 1½ years. 3 months after laying the coating had 1/10 the original resistance and after about 1½ years the value seemed to be stabilized at about 1/20 of the original value. Electrical drainage was used to further protect the pipe. VVK (32)

New Grinding Method for the Edges of Enameling Grates. (Neues Schleif-Verfahren für Emaillierrostspitzen.) SCHICKHARDT. *Emailletechnische Monatsblätter*, Feb. 1932, pages 11-12.

The maintenance of very fine edges of enameling grates is facilitated by a new handy grinding apparatus. The case is made of light metal; weight about 3 kg. In comparing the work time required for sharpening the points by hand with a file with that required by the new apparatus a considerable saving of time can be achieved. GN (32)

The Enameling of Cast Iron. BERNARD B. KENT. *Foundry Trade Journal*, Vol. 46, Apr. 21, 1932, pages 243-244.

The author, after dealing with the production of frit, discusses the type of casting that can be most easily and successfully enameled. Attention is then directed to the sandblasting of suitable castings, and later to the spraying of the castings so prepared. The operations of drying and of fusing are dealt with in order, the article closing with a discussion of the difficulties which present themselves to the enameler during his work. OWE (32)

The Composition of Enamels. I. Ground Coats for Sheet Steel. LUDWIG STUCKERT. *Ceramic Age*, Vol. 19, May 1932, pages 211-213, 237.

The mechanics of enameling steel and cast-iron are explained and the function of the ground coat discussed. After a review of the theoretical and experimental work in this field it is now an accepted fact that the ground coat serves to create a firmly adhering basis on the metal on which the cover coats can be deposited. Composition, fusing points, physical properties desirable in ground coat enamels, especially heat expansion coefficients, are fully discussed. It is concluded that the good bonding power between ground coat and metal is due to the presence of Co and Ni; the reasons for it seem to be a deposition (electrolytically or chemically) in the firing process. Another view is that an iron oxide film must exist on the metal in order to obtain a firmly adhering coat; but this is not quite fully elucidated. 14 references. Ha (32)

ORE CONCENTRATION (33)

Ore-Concentration Statistics in 1930. Metallurgical Results, Flotation Reagents, and Bibliography. T. H. MILLER & R. L. KIDD. *United States Bureau of Mines, Mineral Resources of the United States*, 1930, Part 1, Sept. 1, 1932, pages 749-791.

Nonferrous metal mines in the U. S. produced 76,725,000 tons of ore in 1930 (106,179,000 tons in 1929) classified as follows: Au and Ag 5.01, Cu 62.14, Cu-Pb 0.46, Pb 10.62, Pb-Zn 13.70, and Zn 8.07%. Of the total, 4.79% was of smelting grade, 4.27% was treated at Au and Ag mills, 5.80% was treated by miscellaneous methods (chiefly leaching), and 85.14% was concentrated. Of the total ore concentrated 5.08% was treated by gravity methods only, 58.93% by flotation and 35.99% by gravity and flotation methods combined. In 1930, as in 1929, pine oils, cresylic acid, and orthotoluidine were the only frothing agents used; 98.65% of the ore was so treated. Of the total collecting reagents used during 1930, 81.92% was of the synthetic group and 18.08% of the distillation group, compared with 71.64 and 28.36%, respectively, in 1929. Several new synthetic reagents were introduced during 1930, including Na dibutyl dithiophosphate and certain xanthate derivatives such as "Minerec." The most important collector was ethyl xanthate. Alkalies were used with 92% of the ores (96% in 1929) in about the same amount per ton as in 1929. Lime is of chief importance. Figures are given for each reagent showing the number of plants using it, the tons of ore treated, and the amount used, total and per ton. Similar data are given for each type of ore. Metallurgical data including ore and concentrate compositions and recoveries are given for most of the classifications. A bibliography of 193 references is included. AHE (33)

Experimental Tests on Gold Ore from O'Brien Mine, Cadillac Township, Abitibi County, Quebec. J. S. GODARD. *Canada Department of Mines, Mines Branch, Report*, 724, 1932, pages 69-80.

A Au ore assaying 2.77 oz./ton gave recoveries of 76% by amalgamation alone with grinding to minus 65 mesh, 96% by amalgamation followed by cyanidation of the tailings, 95% by amalgamation and flotation, and 97% by amalgamation, flotation and tabling. Details of 15 tests are given. AHE (33)

Experimental Tests on Gold Ore from the Brookfield Mine of the United Goldfields of Nova Scotia, Ltd., Liverpool, Nova Scotia. J. S. GODARD. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 135-145.

A low grade Au ore assaying 0.21 oz./ton chiefly in arsenopyrite and pyrite and in which 40% of the Au is free was treated by various methods of concentration. Maximum recovery by amalgamation was 52% at minus 100 mesh. Cyanidation recovered 74-86% of the Au with consumption of KCN of ¾ lb./ton and of CaO of 3½ lb. Flotation followed by tabling of the tailings gave 96-97% recovery. Without roasting, 66% of the Au in the concentrates was recovered by amalgamation and 87% by cyanidation. After roasting, amalgamation recovered only 40%; cyanidation 95%, an overall recovery of 91%. AHE (33)

The Recovery of Gold from the Ore of the Casey Mountain Operating Syndicate, Summit Lake, Patricia Portion, Ontario. A. K. ANDERSON. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 150-154.

A magnetiferous quartz carrying Au and small amounts of mispickel, pyrite and traces of galena and chalcopyrite assayed Au 0.72 oz. and Ag 0.11 oz./ton and As 0.42%. Amalgamation gave 82% recovery, flotation 75% and cyanidation 96.5%. AHE (33)

Experimental Tests on Gold Ore from the Central Patricia Mines, Limited, Savant Lake Area, Ontario. J. S. GODARD. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 54-64.

1 Details of flotation, tabling and cyanide tests on an arsenopyrite-pyrite-pyrrhotite-silica ore containing Au 0.60-0.82 oz./ton are given. Cyanidation gave recoveries of 95-98% but with consumption of KCN of 2-6 lbs. and of CaO of 13-27 lbs./ton of ore. Flotation gave 80-90% recovery increased by tabling of the tailings to 93-97%. AHE (33)

Experimental Tests on Gold Ore from the Siscoe Gold Mines, Ltd., Amos, Quebec. J. S. GODARD. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 158-159.

2 A free milling Au ore assaying Au 0.53 oz./ton and S 0.44% gave recoveries of 90-93% by amalgamation, with 6-7% more with flotation of the tailings. AHE (33)

Concentration Tests on Ore Sample from Sudbury Offsets, Ltd., Levack, Ontario. G. B. WALKER. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 44-50.

A norite gangue with chalcopyrite and pyrrhotite and assaying Cu 0.78, Ni 2.43, S 26.10 and Fe 24.21% was concentrated by various methods. Tabling followed by flotation gave no marked improvement. Flotation followed by tabling gives high recoveries of values in low-grade concentrates. Flotation in a circuit made alkaline with soda ash has not produced high-grade concentrates. Use of CaO gives high-grade concentrates with fair recovery. Cyanide partially de-
3 presses Ni and tends to retard Cu flotation if excessive amounts are used. Ni-Fe flotation can be effected by the use of Na_2S, $CuSO_4$, or H_2SO_4. A powerful promoting reagent such as K xanthate or Reagent No. 323 must be used. AHE (33)

4 **Gold Mining and Milling in the United States and Canada; Current Practice and Costs.** CHARLES F. JACKSON & JOHN B. KNAEBEL. *United States Bureau of Mines, Bulletin* 363, 1932, 151 pages.

The geology, exploration, development, mining, milling and costs of producing Au are discussed in detail. The factors affecting the choice of milling methods, including character of ore, tonnage, capital available, water supply, commercial affiliations, royalties, location and general economic conditions are considered. Milling methods are described and numerous examples of current practice are given, together with costs. AHE (33)

5 **The Recovery of Copper and Gold from the Ore of the Tashota Gold Mines, Limited, Tashota, Ontario.** A. K. ANDERSON. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 122-129.

A chalcopyrite-pyrrhotite ore assayed Cu 1.57%, Au 1.85 oz. and Ag 1.87 oz./ton. Results are given of tests with flotation, tabling, amalgamation and cyanidation in various combinations. All tests indicated easy recovery of 90-95% of the Cu. Due to the presence of free air, flotation alone does not yield maximum recoveries of this metal. A combination of flotation, amalgamation and cyanidation yields maximum recoveries. Due to danger of oxidization of the ore before milling, with passage of Cu to the tailing, and because Cu sul-
6 phides are strong cyanicides, a cyanide treatment is not recommended in practice. AHE (33)

Gravity Concentration (33b)

Milling Methods and Costs at the Hillside Fluorspar Mines, Rosiclare, Ill. EDWIN C. REEDER. *United States Bureau of Mines, Information Circular* 6621, May 1932, 20 pages.

A mill feed of fluorspar in calcite and limestone with minor galena and analyzing CaF_2 49.59, $CaCO_3$ 41.78 and SiO_2 6.00% is jigged (Richards) to remove the galena in a concentrate assaying Pb 64.54% and Ag 5.24 oz./ton, or PbS 74.52, CaF_2 12.24, $CaCO_3$ 11.21 and SiO_2 1.52%. The tailings are jigged 7 (Harz) to give a concentrate assaying CaF_2 86.13, $CaCO_3$ 12.58 and SiO_2 0.92%. Undersize material is tabled. Tailings averaging CaF_2 27.15, $CaCO_3$ 64.73 and SiO_2 7.50% are cleaned in a Hancock jig to give final tailings assaying CaF_2 11.06, $CaCO_3$ 72.90, and SiO_2 15.12%. Costs for labor and supplies are $0.542/ton of ore milled. AHE (33b)

Recovering Alluvial Gold. *Engineering & Mining Journal*, Vol. 133, Aug. 1932, page 432.

3 types of Au-saving appliances are illustrated. They are: 8 (1) the cradle or rocker type, where water supply is available, (2) the dry blower, common in Australia, and (3) a dry shaker, where water is scarce. WHB (33b)

Flotation (33c)

Flotation Tests on a Sample of Cyanide Tailings from the Kirkland Lake Gold Mines, Limited, Kirkland Lake, Ontario. J. S. GODARD. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 146-150.

Tailings containing 0.062 oz. Au/ton (associated with pyrite), moisture 23%, H_2O-soluble CaO 0.009% and cyanide 9 a trace were floated with a Au recovery of 62.5% in a concentrate assaying 1.36 oz./ton, largely from the —200 mesh material. AHE (33c)

Starch in the Flotation of Gold Ores. D. N. VEDENSKY & L. H. DUSCHAK. *Engineering & Mining Journal*, Vol. 133, June 1932, pages 334-335.

Soluble starch has been effective as a depressant of certain minerals, the results being especially advantageous where the ratio of concentration is high. Results of experimental work at the 2 mills of the Idaho-Maryland Mines Consolidated, at Grass Valley, Calif. on the effectiveness of soluble 10 starch show that: (1) soluble starch is useful in the flotation of Au ores in California, (2) the useful effects are dependent upon the employment of true soluble starch, (3) an inexpensive method of preparing soluble starch at the plant has been worked out, and (4) true soluble starch may have further applications in flotation. WHB (33c)

Flotation of Gold Ores Offers New Opportunities. MAX W. BOWEN. *Engineering & Mining Journal*, Vol. 133, Aug. 1932, pages 448-449.

A brief discussion is given of the Au ores to which flotation processes are applicable, the types of machinery, the reagents used, and the factors to be considered in designing a flotation plant for treating Au ores. WHB (33c)

The Concentration of Silver in the Ore of the Animikie Mines, Ltd., Port Arthur, Ontario. A. K. ANDERSON. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 90-94.

Proustite in an ore of limestone and calcite gangue carrying a small amount of Fe sulphide gave the ore an assay of Ag 46.0 and Au 0.02 oz./ton. Flotation can be depended on to yield a recovery of 95% of the Ag in a concentrate (refloating of a rougher product) assaying Ag 2000 oz./ton. The circuit was alkaline (5 lbs. soda ash/ton); Aerofloat No. 25 was used at the rate of 0.20 lb./ton. AHE (33c)

Investigations on the Flotation of Cassiterite. (Untersuchungen über die Flotation des Kassiterites.) G. GERTH. *Archiv für Erzbergbau, Erzaufbereitung, Metallhüttenwesen*, Vol. 2, Mar. 1932, pages 1-20.

Report from the Ore Dressing Laboratory of the Mining Academy, Clausthal, Germany. The flotation of oxide minerals is discussed. Artificial mixtures of Sn oxides and quartz and then natural Saxonian Sn ores were floated. In both the natural and artificial Sn ores the gangue is floated from the ore with sodium oleate, provided one succeeds in generating on the gangue an adherent coating of silicic acid gel. The methods of generating such coating have been developed in the investigation and the results of the flotation experiments show that the Sn ore can be separated practically completely from its gangue by using these methods. However, the separation is complete only when quartz and mica are the chief gangue minerals. Since losses up to 50% are common with the mechanical methods used at present for separating Sn from its ores, the newly developed flotation method should take a predominant position in Sn ore dressing. 4 references. GN (33c)

Flotation Tests on Ore Sample from Amulet Mines, Limited, Rouyn, Quebec. G. B. WALKER. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 94-101.

A complex ore of chalcopyrite, sphalerite, and pyrite assaying Cu 3.95 and Zn 20.52% was treated by flotation. Use of Reagent No. 301 in conjunction with thiocarbanilide will effect higher recovery of Cu consistent with concentrate grade than the combination of thiocarbanilide and xanthate. Increased amounts of Aerofloat No. 25 resulted in lower Zn tailings. Na aerofloat effected the highest grade Zn concentrates, an average of 56.63% Zn. Reagent No. 208 gave higher grade Zn concentrate than xanthate. AHE (33c)

Milling Methods and Costs at the Concentrator of the Britannia Mining and Smelting Co., Ltd., Britannia Beach, B.C. A. C. MUNRO & H. A. PEARSE. *United States Bureau of Mines, Information Circular* 6619, May 1932, 24 pages.

The chief Cu mineral in a sulphide replacement ore in chlorite schists is chalcopyrite; minor amounts of chalcocite and bornite are present. A bulk concentrate is produced containing chalcopyrite and pyrite with minor Au and Ag; this is ground and refloated to produce a Cu and a pyrite concentrate and middling which are retreated. A blanket Au-recovery unit is provided between the cells producing Cu concentrate and those producing pyrite concentrate. Reagents are: hydrated lime 1.10, K ethyl xanthate 0.04, Aerofloat No. 25 0.005, and pine oil 0.15 lb./ton of ore. Total Cu recovery is 89.36%, sulphide Cu 90.71%. Total costs (details given) are 17.70 cents/ton. AHE (33c)

Flotation Tests on Ore Sample from Denison Copper Mines, Ltd., Worthington, Ontario. G. B. WALKER. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 50-54.

A chalcopyrite-pyrrhotite-norite ore assaying Cu 1.27, Ni 1.15 and S 5.73% was treated by flotation. In a circuit made alkaline with soda ash, a bulk Cu-Ni concentrate can be obtained with cresylic acid. High Cu recovery is indicated. The addition of 0.10 lb./ton of Aerofloat No. 25 increases Cu and Ni recovery in a lower-grade product. For the flotation of a Ni-Fe product, a H_2O-soluble promoting agent must be used. In a CaO circuit much higher grade Cu concentrates can be produced. The use of cyanide in conjunction with CaO has resulted in the most marked separation obtained. After the Ni-bearing pyrrhotite has been depressed by CaO and cyanide, it is most difficult to float. AHE (33c)

The Concentration of the Copper-Nickel Ore of the Falconbridge Nickel Mines, Ltd., Garson, Ontario. C. S. PARSONS, G. B. WALKER & A. K. ANDERSON. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 29-44.

An ore of sulphides of Cu, Ni and Fe in a basic gangue assaying Cu 1.11 and Ni 2.28% was jigged, concentrated on a Butchart table, concentrated on a Plato table and floated. Gravity concentration gave little improvement. Grinding with soda ash 4.0 lb./ton of ore, flotation of Cu with cresylic acid 0.04 lb. followed by flotation with 0.20 lb. American Cyanamid Reagent No. 404 or 0.20 lb. No. 323 + 0.20 lb. cresylic acid gave recoveries of 99% of the Cu and 95% of the Ni. AHE (33c)

The Concentration of the Cobalt Ores of the Aganuico Cobalt Mines, Limited, Cobalt, Ontario. A. K. ANDERSON & D. S. HALFORD. *Canada Department of Mines, Mines Branch, Report* 724, 1932, pages 80-90.

An ore of cobaltite, smaltite and erythrite in a diabase gangue with small amounts of calcite assaying Co 2.60 and Ni 0.60%, Ag 0.22 and Au 0.02 oz./ton was treated by flotation. Using soda ash 7.0 and Flotagen 0.05 lb./ton in the ball mill and Flotagen 0.10, pine oil 0.25, and $CuSO_4$ 1.0 lb./ton in the flotation machine a concentrate (11.93%) assaying 17.76% Co and containing 83.67% of the Co, a middling (10.16) of 1.54% Co containing 16.18% more of the Co and a tailing (77.91%) assaying 0.33% Co was obtained. Flotation tests were made on samples from various parts of the present plant (using gravity separation) with varying success. AHE (33c)

Milling Methods and Costs at the Pecos Concentrator of the American Metal Co., Tererro, N. Mex. H. D. BEMIS. *United States Bureau of Mines, Information Circular* 6605, May 1932, 23 pages.

1 A complex Ag- and Au-bearing ore containing, in the order of abundance, the following sulphides: pyrite, sphalerite, galena, chalcopyrite, marmatite, chalcocite, bornite, argentite, and proustite, and a gangue of chiefly mica, quartz, tourmaline and hornblende is treated by flotation. Costs for 1930 in cents/ton of ore, were: superintendence 8.95, grinding 27.16, flotation 22.54, reagents 29.46, tabling 3.82, sampling 2.05, thickening 0.25, H_2O 5.37, filtering 3.75, heating 0.71, tailings disposal 0.08, lighting 0.45, lubrication 0.40, mill clean up 1.80, miscellaneous 0.13, experimental 3.20, laboratory 5.95, royalties 2.93 and total $1.1898. AHE (33c)

Magnetic Separation (33d)

2 **Fe Losses in Magnetic Separation. (Om järnförlusterna vid magnetisk separation.)** E. ROTHELIUS. *Jernkontorets Annaler*, Vol. 116, Feb. 1932, pages 62-94.

3 The following conclusions are drawn as to the effect of screening and sorting material before magnetic separation: (1) Screened material gives the best result on magnetic separators. (2) Sorted material gives better results than unsorted or unscreened ore but somewhat inferior to that which is screened. (3) Sorted magnetite is easily separated on tables. Although the recovery is less complete on magnetic separators mixed grains are more easily separated from the concentrate. Coarser clean concentrates are more easily obtained on tables than on separators. (4) Dispersion materials, such as low boiling petroleum fractions, may sometimes facilitate magnetic separation. HCD (33d)

4 **Magnetic Concentration Methods and Costs of Witherbee, Sherman & Co., Mineville, N. Y.** T. F. MYNERS. *United States Bureau of Mines, Information Circular* 6624, June 1932, 27 pages.

The feed is magnetite associated with apatite and gneiss of 2 types—(1) hornblende, biotite and no quartz and (2) no hornblende and biotite and much quartz. In 1930, from ore containing Fe 52.57%, 1 mill gave a concentrate containing 67.49% Fe at a recovery of 95.59% and a cost of $0.437/ton of concentrate. Costs for both mills are $0.394/ton of concentrate. AHE (33d)

5 **New-Type Magnetic Separators for Weak Magnetic Ores and Coals. (Beachtenswertes über neuzeitliche Magnetscheider für schwachmagnetische Erze und Kohlen.)** J. F. KESPER. *Kali, Erz und Kohle*, Vol. 29, June 10, 1932, pages 86-87.

Description of new types of magnetic separators recently built in Germany. GN (33d)

6 **Magnetic Separation of Faintly Magnetic Bodies in Falling and Horizontal Throw. (Magnetische Aufbereitung schwachmagnetischer Körper im freien Fall und im horizontalen Wurf.)** B. GRANIGG. *Archiv für Erzbergbau, Erzaufbereitung, Metallhüttenwesen*, Vol. 2, Mar. 1932, pages 21-25.

Report from the Mineralogic Institute of the Mining Academy at Leoben, Austria. Magnetic separation of free falling material is discussed; the disadvantages of the Edison separator are mentioned. Magnetic separation of material moving through the magnetic field in an inclined position is considered. A separator in which the material passes the magnetic field in a horizontal throw is described. The new magnetic separator is called a "mushroom" separator due to the shape of the central magnet pole. The separator is to be used for dry as well as wet separation. 4 references. GN (33d)

Crushing (33e)

Designs of Typical Jaw-Crushers. *Crushing & Grinding*, Vol. 1, Mar.-Apr. 1932, pages 131-132.

The history of jaw crushers is traced and line drawings of 11 machines are given. AHE (33e)

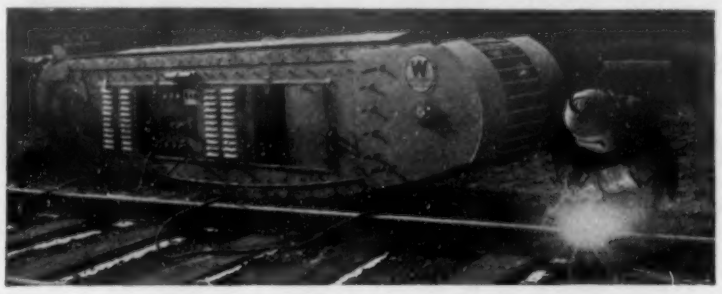
A series of 6 tables are presented by C. L. Dewar as discussion of the paper abstracted in *Metals & Alloys*, Vol. 3, May 1932, page MA 154. AHE (33e)

The Use of a Composite Grinding Load in Tube Milling on the Witwatersrand. F. WARTENWEILER. *Journal Chemical, Metallurgical & Mining Society of South Africa*, Vol. 32, May 1932, pages 262-282.

8 Using a mixture of steel balls and ore pebbles (about 1:2) as the grinding medium in tube mills in 3 plants, capacities were increased (15% in 1 plant) over those for straight pebble-mill grinding. A shortage of suitable pebbles made the step necessary. In one plant a more selective grinding and an increase in extraction resulted. Operations at these 3 plants are described and detailed data presented. Liner life is increased about 7% when using the composite load. Cyanide consumption has not been increased by the Fe. Power consumption is increased 15-17%. Milling costs are given and show no overall rise by the use of a composite load. AHE (33e)

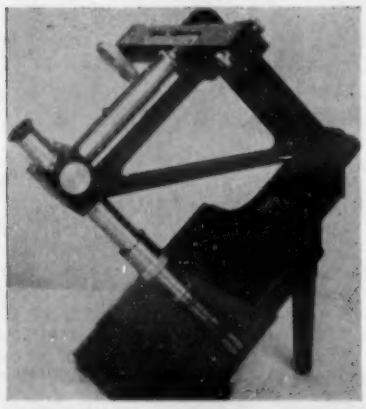


9 **Influence of the Microstructure and of Roasting on the Crushing Properties of Certain Fe Ores. (Mikrostrukturens och rostningens inflytande pa förloppet vid krossning av vissa järnmalmer.)** P. J. HOLMQUIST. *Jernkontorets Annaler*, Vol. 116, Mar. 1932, pages 119-148.

10 The observation that Fe ores are more easily crushed after roasting is explained by the fact that the material breaks along the grain boundaries. Experiments failed to show that roasting facilitated either clean-crushing or a more effective concentration. In quartz-bearing hematites, this was due largely to the distribution of the hematite in fine grains throughout the quartz, and to the recementing of the material during roasting. The grain size curves have the same form for roasted and non-roasted ores, but after roasting the sizes corresponding to the dominating grain sizes in the original ore are much more prevalent, showing that the material breaks up along the grain boundaries. The grain boundaries of crystalline aggregates were found to act as surfaces of weakness during the crushing process. 8 references. HCD (33e)

New Equipment and Materials

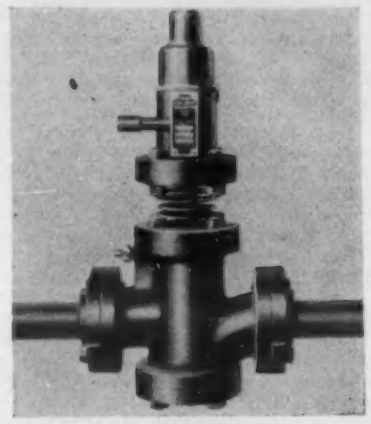
Welder for Railroad Maintenance, Etc.



Developed by the Westinghouse Electric & Mfg. Co. to fill the need for a mobile power supply unit which does not require frequent transferring to and from the track for movement from one point to another, a new welder eliminates the use of long cables, does not interfere with traffic, is capable of operating along the shoulder of the track entirely clear of trains, can ascend slopes up to about 35° and is stable in operation on side slopes of 45°. The welding and power unit are self-contained, furnishing welding current for one operator, power for tools and power for propelling the tractor. The moves are made quickly by one man and do not interfere with the right of way. The tractor operator when not moving the tractor is able to do all of the slotting and grinding operations of the newly welded joints. Pivot

turns are possible on any kind of ground, but a platform is usually carried with the tractor for use in crossing tracks and for convenience in making pivot turns. The overall width is 30 in. and the height is 36 in. A bulkhead is built into the rear of tractor frame on which the 2 propulsion motors are mounted. This bulkhead, motors, worm gearing and tread sprockets are removable as one unit, thus facilitating maintenance. A Westinghouse FlexArc welding generator provides welding current for one operator and will handle both bare electrodes at the lower voltages and coated electrodes at higher voltages. Both the welding and auxiliary generator control equipment are mounted on a panel alongside of the unit frame generators. Sliding doors give access to all controls. The gasoline power unit is a Buda, 6-cylinder, 65-h.p. engine. The 2 propulsion motors take their power from the variable voltage, constant current, welding generator.

Metals & Alloys, May 1933.



Microdensitometer

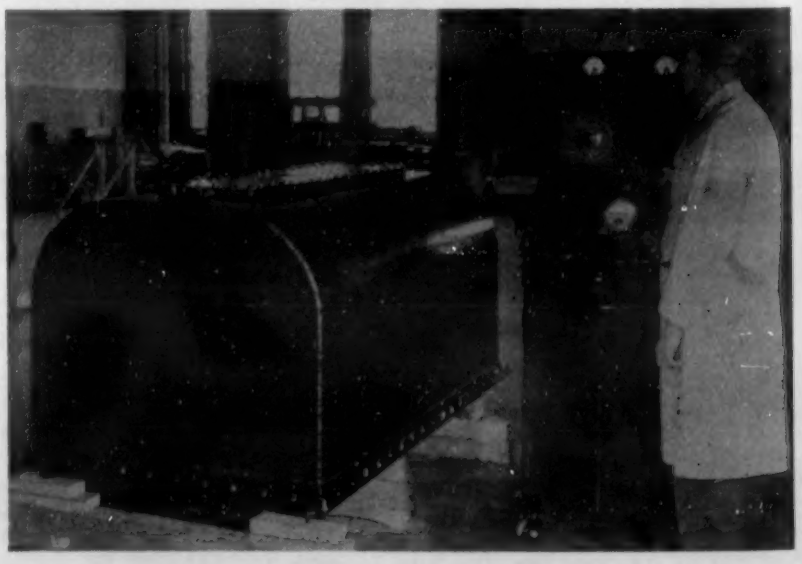
This instrument is especially designed for measuring the densities of spectrum lines on photographic plates, and consequently for making quantitative photometric determinations of the intensities of spectrum lines in the visible ultra violet and X-ray regions. It has recently been brought out by the Gaertner Scientific Corp., Chicago. The density of the plate to be measured is compared photometrically with the known density of a neutral absorbing wedge which provides varying amounts of illumination to one part of the photometric field as different integrals of the wedge are used. The wedge and plate are illuminated symmetrically and the 2 resultant beams are compared by means of a photometer cube. Provision is made for compensating for the grain of the photographic plate. The spectrum lines are clearly visible in the field while measurements are made. *The photometric field* is produced in a photometer cube at the focal plane of the eyepiece. A strip 2 mm. wide is silvered on an interior diagonal face of the cube, with the exception of a small central portion 0.1 mm. in width which divides the strip into 2 equal longitudinal parts. The spectrum line to be measured is selected and brought into position midway between the 2 portions of the strip producing a continuous field. The wedge is then manipulated so as to match both sides of the strip with the spectrum line, resulting in a continuous strip of uniform intensity. *The neutral absorbing wedge* is 100 mm. long and its position is indicated by a millimeter scale and index. The variable densities of this wedge are proportional to its displacement on the scale, the range being from 0 to 4. These figures represent the logarithms of the reciprocals of the transmission coefficients of the wedge, thus: the range of transmitted light is from 1 to .0001. Exact matching of the photometric field is possible without defocusing. *The microscopes* transmitting the 2 paths of light to the photometer cube are optically similar, and are fitted with 36 mm. E.F. objectives. The field is viewed through an eyepiece of 25 mm. E.F.L. at a magnification of about 15 diameters. About 5 mm. of the spectrum plate may thus be seen at one time. Adjustable draw tubes permit the use of the instrument in a lighted room.

Metals & Alloys, May 1933.

Remote-Reading Liquid Meter

Complex and costly arrangements usually needed in order to meter heavy oils, chemicals, etc., are not required when installing a new type of fluid meter brought out by The Brown Instrument Co. It consists of two main elements: the meter body and electrical transmitter (illustrated), and the receiving instrument which may be a round-chart recorder, a dial indicator or a combination of these two. The primary element is of the "area" type. It consists essentially of a piston-and-sleeve arrangement whereby a fixed pressure drop is maintained and the position of the piston both regulates the area and corresponds to the quantity-rate of flow. To the piston is fixed a rod, the upper end of which carries the armature of an inductance-bridge transmitter. This armature travels up and down in a non-magnetic tube which separates the fluid meter from the electrical parts without need of stuffing boxes. Sizes (based on water metering) range from 150 g.p.h. capacity to 2000 g.p.h. capacity.

Metals & Alloys, May 1933.



Rubber-lined Valve

Designed for handling corrosive and abrasive fluids, a new rubber-lined valve, the Vulcalock valve, announced by The B. F. Goodrich Rubber Co., Akron, O., may be lined with any of the standard Goodrich Acidseal rubber compounds, hard or soft, depending upon conditions of service. It represents a distinct departure from previous valve design. Its cost is moderate. Its action does not depend upon a flexible diaphragm; the resilient, rounded disk which snaps over a circular plate at the lower end of the stem provides a positive seal when brought into contact with the molded rubber-covered seat. Both disk and ring are simple, inexpensive, easily replaceable parts. A steady, uniform flow with positive shutoff is obtained under severe operating conditions. Corrosive or abrasive materials come in contact only with rubber especially designed to resist their deteriorating action. On sizes up to and including 6 inch, there is no restriction of flow through the seat ring. The valve may be taken apart completely and easily and quickly reassembled without special tools. Disk and seat removed and replaced with especial ease.

Metals & Alloys, May 1933.

Large X-ray Apparatus

The most gigantic task ever assigned to industrial X-ray work is the minute inspection of every inch of 75 miles of steel welds in the penstocks for Hoover Dam. A special shock-proof apparatus rated at 300,000 volts was developed for the job by the General Electric X-Ray Corp., Chicago, Ill. Complete safety in dealing with such high voltages, space limitations, and necessarily easy portability made the

development of the apparatus difficult. Rated at 300,000 volts and 10 milliamps for continuous operation, it is capable of producing radiographs of welded steel plate 4" thick. The high voltage required made the safety factor important. It is impossible for anyone to come in contact with the high-tension system while operating. The apparatus consists of 3 units—a shock-proof head weighing 5,000 lbs., the operator's control unit, and an expansion tank.

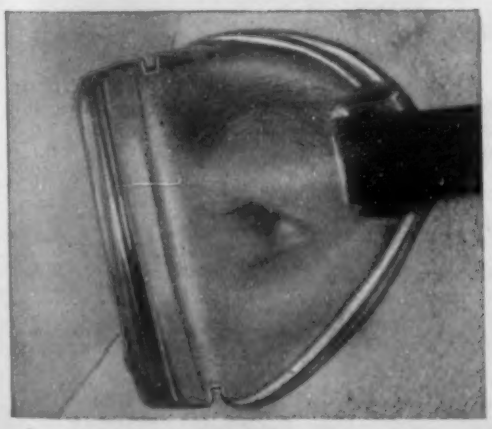
Metals & Alloys, May 1933.

Light Gage, High Speed, Precision Flying Shear

A new high speed precision flying shear for light gage cold strip was developed by United Engineering & Foundry Company, Pittsburgh, Pa. The shear is designed to handle strip up to 36 inches wide from .006 to .025 inches thick into any selected length from 12 to 26 inches in increments of 1/64, and from 26 to 52 inches by increments of 1/32. The action is continuous and fully automatic. It operates at a maximum speed of 300 feet per minute, claimed to be a much higher speed than has been obtained by other flying shears for this type of material. The importance of obtaining each length exactly as desired without error has necessitated the designing of a gear box having a total of 832 changes of speed and eliminates the hazard of frictional and hydraulic contrivances. The change of speed of the gear box to obtain different lengths is quickly effected by moving three levers conveniently located on one side of the gear box. It takes approximately 80 seconds to effect the gear change and not over 20 seconds to change the guides. An ingenious device is applied to the knife operating levers for changing the setting of the knives while operating.
Metals & Alloys, May 1933.

Tantalum Carbide Tools

Announcement has been made by the Ramet Corp. (subsidiary of Fansteel Products Co., North Chicago, Ill.), of the development of a complete line of Ramet tantalum carbide tools for cutting, drawing and working all metals. *Grade A*: For general service in machining cast-iron and non-ferrous materials in which there is edge wear and only a slight tendency towards cratering. *Grade AA*: Similar, but specially designed for intermittent cuts and heavy duty applications involving shock. *Grade B*: For cutting materials requiring combination of resistance to cratering and edge wear such as cast alloys used in crankshafts, etc., steel screw stock with high sulphur and phosphorus content, etc. *Grade C*: In general, for soft steels which have the greatest tendency to cause cratering. *Grade D*: Similar to Grade C but for harder steels and high speed operation. *Grade X*: High resistance to both cratering and edge wear. Suitable for very hard steel (above 450 Brinell) and for manganese steels having 12 to 14% manganese content.



In addition to cutting applications, wire, tubing, and extrusion, dies have been developed from *special grades* of Ramet to give any desired characteristics. Ability to withstand corrosion is pointed out as an advantage in connection with acid dips or washes. Another is the high finish applied to products worked which commands premium prices. In a comparative test, 7000 lbs. of .0114" steel weaving wire was drawn per recutting of Ramet dies against an average of 30 lbs. per recutting of steel dies. Other interesting applications include highly polished and extremely hard friction disks, needle valves, scribers, knife edges for scales, gages, micrometers, spring coiling arbors, and forming tools of various types.
Metals & Alloys, May 1933.

Non-Metallic Bearings

Gatke bearings are now available in a complete line for all general machinery uses, announces the Gatke Corp., Chicago, Ill. Gatke non-metallic bearings are composed of a special textile base impregnated with synthetic resins, molded under high pressures. Gatke Hydrotex bearings are recommended wherever bearings run in water or where water is available for lubrication; Gatke Lubritex bearings are designed for equipment that is oil lubricated; Gatke Grafitex is self-lubricating and especially made for slow moving machinery, where dirt and grit are encountered or where lubrication is neglected. Bearings of all 3 materials are already furnished for journal diameters from ⅛" to 24" and can be made to larger sizes.
Metals & Alloys, May 1933.

Transparent Cup Goggles

Willson Products, Inc., Reading, Pa., point out that "goggle kickers" are in a measure justified in their complaints, because of the usual "blinder" feeling. The cups of the new Willson Goggle are made of a transparent material which enables the wearer to perceive objects through them. The "blinder" feeling is entirely eliminated and the operator obtains a visual comfort heretofore unattainable. No sacrifice of the elements that go into making a good goggle was necessary to obtain cup transparency. The goggle is sturdy, spark-proof, extremely light in weight, roomier, better ventilated, serves well for all-purpose use and can also be worn over spectacles.
Metals & Alloys, May 1933.

The Expression—

"A mine of information"

takes on a vivid meaning when applied to the

Cumulative Index of Metallurgical Abstracts

published in METALS & ALLOYS from July 1929 to December 1931. Here are the bare facts about this newly-published compilation:—

15,700 listings

THE CHEMICAL CATALOG COMPANY, Inc.
330 West 42 Street, New York, N. Y.

MANUFACTURERS' LITERATURE REVIEWS

93 **Rust Prevention**—For the protection of bright steel goods or parts in transit and export shipments where the danger of corrosion is great, "Croda Fluid" is recommended in a leaflet sent out by Cox, Aspden & Fletcher, New York, N. Y. This coating may be applied by brush, spray or immersion and is furnished in three grades to meet different requirements.

94 **Rezistal**—Several folders issued by the Crucible Steel Company of America, New York, N. Y., illustrate applications of their Rezistal KA-2. This is a high chromium-nickel steel which has been given special processing and heat treatment which make it easy to fabricate. It is particularly recommended for use in dairy equipment and in culinary departments of institutions, and can be used to good effect in architectural design in grille work, metallic doors, window frames, etc.

95 **Forging Machinery**—A recent catalogue of the National Machinery Co., Tiffin, Ohio, contains descriptions of the various types of forging machines manufactured by them in addition to descriptions of bolt, nut, rivet and wire nail machinery.

96 **Chrome Nickel Silver**—A folder issued by the American Nickeloid Co., Peru, Ill., describes their new metal, chromium bonded to a nickel silver base, and it contains a small sample of the material.

97 **Allegheny Metal**—Bulletin A-10 of the Allegheny Steel Co., Brackenridge, Pa., illustrates applications of their Allegheny Metal in the dairy products industry, in building construction and in a great variety of unusual applications. Bulletin A-1 of the same company gives the chemical composition of this metal, its resistance to various media and its physical properties.

98 **Welding Electrodes**—An attractive booklet sent out by the Metal & Thermit Corporation, New York, N. Y., gives a general description of their "Murex" heavy mineral coated electrodes, discusses the advantages experienced in their use and describes the different types of these electrodes. Another pamphlet issued by the same company is devoted to the problem of welding manganese steel by the "Murex" method.

99 **Portable Blow Torch**—A leaflet recently sent out by the North American Manufacturing Co., Cleveland, Ohio, is devoted to their portable blow torches and some of their various applications. This company has also prepared bulletins showing the prices of their oil and air proportioning valves for manual control.

100 **Gas Producer**—A folder issued by R. D. Wood & Company, Philadelphia, Pa., gives a condensed description of their automatic gas producer, type SB. One page contains an interesting set of illustrations showing the various types of gas producers manufactured by the company since 1889.

101 **Molybdenum in Cast Iron**—The 1933 Supplement to their publication, Molybdenum in Cast Iron, has been prepared by the Climax Molybdenum Co., New York, N. Y. It gives a summary of the effect of Mo on gray iron, with and without Ni or Cr, and includes some data from recent literature on the subject.

102 **Properties of Toncan Iron**—A small booklet issued by the Republic Steel Corp., Massillon, Ohio, contains complete data on Toncan Iron, its composition, physical constants, physical properties and heat treatment being given.

103 **How to Make your Own Carboloy Tools**—A 16-page booklet issued by the Carboloy Co., Detroit, Mich., contains a complete description of the method used to mill the shank steel and the braze Carboloy tip to the shank. It also includes data on design and gives a listing of the accessories necessary.

104 **Testing Machines**—Practically all types of testing machines are illustrated and described in Catalog 50 Part H published by the Tinius Olsen Testing Machine Co., Philadelphia, Pa. It includes testing machines for efficiency of cutting or abrasion tools, alternate stress in materials, impact, torsion, cold bend, hardness and for other special purposes. It will be sent free to those requesting it on company letter-heads. To others the price is $1.00.

105 **Microscopes**—A recent pamphlet of Carl Zeiss, Inc., New York, N. Y., is devoted to their binocular microscope the magnification of which can be varied between 4X and 43X. It can be had with various types of stands for different purposes, and its standard equipment includes three pairs of eyepieces and three pairs of objectives.

106 **Electrunite**—This new type of boiler tube, made by electrical resistance welding, may be used in either firetube or water-tube boilers requiring straight or bent tubes. They are described in a leaflet sent out by Steel and Tubes, Inc., Cleveland, Ohio.

107 **Zinc Die Castings**—The third issue of The Alloy Pot, published by the New Jersey Zinc Co., New York, N. Y., features an article describing zinc die castings in an inexpensive electric clock. A table showing the impact strength of zinc die castings as compared with sand cast malleable iron and brass is included.

108 **Electric Contact Controller**—Bulletin 184 of the Foxboro Co., Foxboro, Mass., describes their "Rotax," an electrically operated controller with rotating contacts which may be applied to instruments for controlling pressure, temperature, humidity and liquid level.

109 **Boilers**—A folder just sent out by the Titusville Iron Works Co., Titusville, Pa., illustrates various types of their boilers, giving in detail the special features of their "S.R." series.

110 **Furnaces**—A current folder of the Surface Combustion Corp., Toledo, Ohio, gives the operating data of several of their standard furnaces used in a modern heat treating plant, using the batch method of heat treating.

111 **Combating Chemical Corrosion with Aluminum**—A 43-page booklet prepared by the Aluminum Company of America, Pittsburgh, Pa., deals with the use of aluminum in the construction of chemical apparatus and equipment. The effect of different chemical reagents on the metal are considered separately.

112 **Corrosion Resistance**—E. F. Houghton & Co., Philadelphia, Pa., have produced a paint-like finish, "Houghto-Kote," which not only gives protection against rust but also has a high resistance to acid, brine, heat and corrosive fumes and gases. It is made with a gilsonite base and can be had in five colors.

113 **Duroline Pipe**—Cement-lined pipe manufactured by the National Tube Co., Pittsburgh, Pa., is discussed in a 16-page booklet sent out recently. It fills the demand for a product combining the good qualities of iron or steel pipe, exceptional corrosion resistance, and a price permitting its general use.

114 **Simple Testers**—Circular No. 107 of the Amthor Testing Instrument Co., Brooklyn, N. Y., describes a new portable bursting strength tester, new tensile strength testers and a new pocket thickness gage designed for rapid testing of wire, rubber, cordage, etc. Their Circular No. 106 describes their automatic fixed reading tachometer for speed measurement of revolving equipment such as motors, pulley shafts, belt surfaces, etc.

115 **Oil Burner**—A folder issued by the Industrial Combustion Corp., Buffalo, N. Y., discusses the Sell high pressure oil burner with which perfect atomization can be obtained with all grades of fuel oil. It is applicable to such furnace installations as annealing ovens, crucible furnaces, blow torches, forging furnaces, galvanizing furnaces, etc.

116 **"Lectrodryer"**—A recent circular distributed by the Pittsburgh Lectrodryer Corp., Pittsburgh, Pa., is devoted to their new "Activated Alumina System" for drying air and gases. It can be used in controlled atmosphere annealing of deoxidized sheet, dehumidification of warehouses and special process rooms, industrial and chemical processes and gas conditioning.

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Germany Fights Gas Main Corrosion With Tetralin. A. C. BLACKALL. *Gas Age-Record*, Vol. 70, Sept. 24, 1932, page 317. Tetralin (tetrahydronaphthalene) is a colorless, easily mobile liquid with a specific gravity of 0.9725 at 60° F. and a boiling point of 404° F. It is a hydrogenated naphthalene and possesses the property of dissolving large quantities of naphthalene. At 60° F. 80 parts of tetralin will absorb 20 parts of naphthalene. It will dissolve almost anything of aromatic character but will not dissolve asphalt. It is used in Germany for removing old naphthalene deposits, tar and gummy rust deposits from gas mains and preventing their occurrence. 2 methods are used. In the "cold process" the tetralin is forced through an injector where it is transformed to fog and the individual particles are quickly vaporized by absorbing heat from the gas. In the second method the tetralin is vaporized by means of electric heating units. An installation at a central point is sufficient for the entire system. VVK (4) 1

The Internal Corrosion of Gas Transmission Lines. A. B. ALLYNE. *Gas Age-Record*, Vol. 70. Sept. 10, 1932, pages 267-268. Considerable internal corrosion was found in the gas transmission lines of the Southern Counties Gas Co., Los Angeles, Calif., which on investigation resulted in the following conclusions. (1) Oxygen, present only in fractions of a percent in a gas mixture, may cause severe internal corrosion when compressed and sent into a transmission system. (2) This corrosive agent enters the lines chiefly due to leaks in vacuum-collected gathering systems. (3) Due to inaccuracies in ordinary gas analysis equipment, small quantities of oxygen are either disregarded or pass undetected. (Samples were collected in special tanks made of Cu pipe and analyzed in the laboratory using chromous chloride as an absorbent.) (4) To properly prevent serious internal corrosion due to rusting, it is necessary to reduce the oxygen content to 0.2% or less. VVK (4) 2

A Soil Corrosion Survey With Shepard Soil Resistivity Rods. A. V. SMITH. *Gas Age-Record*, Vol. 70, Oct. 15, 1932, pages 403-408. Paper presented before the American Gas Association, Oct. 1932. A soil corrosion survey using Shepard soil resistivity rods was made of 10,000 ft. of a 12" line installed in 1914. Soil resistivity measurements were made every 50 ft. Areas of low resistivity and more particularly areas of low resistivity bounded on both sides by areas of high resistivity showed considerable corrosion. The measurements were also checked by excavations in high resistivity areas and the pipe was found in excellent condition. The rods seemed to indicate corrosive conditions, whether they were due to acid or alkaline soil. They were also useful in locating leaks in areas where the soil resistance was above 5000 ohm-centimeters. Where a gas leak occurs in the soil the resistance of the soil will be lowered to values ranging between 500 and 2000 ohm-centimeters, depending on the time the gas has been leaking. A total of approximately 1300 ft. of main in very bad condition was removed and replaced. VVK (4) 3

Soil Studies for Existing Pipe-Line Systems. WILLIAM THOMPSON SMITH. *Gas Age-Record*, Vol. 70, Oct. 8, 1932, pages 369-370, 382, 390. Discussion of the value and procedure for soil studies for pipe-line systems already in the ground. VVK (4) 4

How Soil Corrosiveness Can Be Measured. WILLIAM THOMPSON SMITH. *Gas Age-Record*, Vol. 70, Aug. 6, 1932, pages 129-134, 143; Discussion, Oct. 8, 1932, pages 377, 385. A critical review of the methods in use for determining the corrosiveness of soils. These include historical methods, ground moisture determinations, the hydrogen evolution method, total acidity measurements, loss of weight method, the geological method, electrical methods and chemical analysis. VVK (4) 5

Electrical Methods for Estimating the Corrosiveness of Soils. SCOTT EWING. *American Gas Association Monthly*, Vol. 14, Aug. 1932, pages 356-360. Inspections of numerous pipe lines indicate clearly that soils differ greatly in rate at which they attack Fe and steel. Present study was for purpose of learning something about accuracy of various devices for testing corrosiveness. Different methods are described but Columbia soil rod was used for study. This employs one steel and one Cu electrode and galvanic potential between these dissimilar metals constitutes only source of current, no battery being used. A field study was made along pipe lines in Ohio, Indiana and West Virginia. On basis of this experience it was found possible to divide inspection points into 4 classes as follows: (1) Small isolated areas along so-called "sulphur streams" and seepage areas where soil and water contain a high percentage of soluble material. In these pipe usually lasts about 5 years. (2) Low, poorly drained, mucky areas where the pipe life is about 10 years. (3) General typical upland soils of Ohio and Indiana. Pipe as old as 25 years is still in service in these soils, but leaks usually begin after about 15 years. (4) Rough, steep topography in which pipe will last at least 30 years and longer. Readings are plotted from each of these areas showing satisfactory separation. Measurements of galvanic current and of soil resistivity roughly indicated corrosiveness of soils tested but laboratory trials showed that this would not be true for all types of soils. Considerable detail is given regarding tests conducted and results found. RJC (4) 6

Protective Films on Metals. E. S. HEDGES. D. Van Nostrand, New York, 1932. Cloth, 5¾×8¾ inches, 276 pages. Price $5.00. This is a large correlated abstract in book form, which shows the state of the art in very concise and useful form. It does not attempt to include an exhaustive bibliography, but it does skim the cream of the recent important articles. 7

The mechanism of corrosion is discussed in relation to the effect of films, film formation in the atmosphere and in liquid media, electrolytic films, oxide films from the practical point of view, hot dipping, electroplating, metal spraying, so-called "cementation" (sherardising, chromising, and calorising), etc. are covered. A very brief appendix relates to paints, lacquers, enamels, etc. but these are only casually mentioned. The book is one of a series of monographs on applied chemistry, edited by E. H. Tripp. The point of view throughout is that of the chemist, which is decidedly as it should be. The book will be much used by those concerned with corrosion problems or with the development of alloys or coatings for corrosion and tarnish resistance. Its value lies not merely in the convenience of a collection of excerpts from the literature, but also in the thoughtful and thought-provoking way in which the facts and theories have been put together to form as complete a picture as can be drawn today. HWG (4)-B 8

Cases of Incrustation and Destruction in the Pipe System of the Schwenningen Water Supply System. (Verkrustungs- und Zerstörungserscheinungen im Leitungsnetz der Schwenningen Wasserversorgung.) K. HERRMANN. *Gas und Wasserfach*, Vol. 75, Nov. 5, 1932, pages 890-893. Interesting cases of corrosion caused by a certain type of alga are described. Incrustation was accelerated by defects and injuries of asphalt coating of the pipes. GN (4) 9

Protection of Iron Immersed in Aerated Salt Solutions by Cathodic Polarization. (Protection, par polarisation cathodique, du fer plongé dans les solutions salines aérées.) E. HERZOG & G. CHAUDRON. *Comptes Rendus*, Vol. 193, Oct. 12, 1931, pages 587-589. Using an Evans cell to which salts of Zn, Pb, Ni, Mn, Mg, and Cr were added, the polarized cathode, on which oxides of metals are deposited, becomes more electro-negative and assumes a potential near that of the active anode. Except for Pb, the potentials of the anode remain almost the same. It is concluded that the Fe will not be protected by PbO, nor when the Fe has a high Cr content. OWE (4) 10

Pipe-Line Protection. STANLEY GILL. *Industrial & Engineering Chemistry*, Vol. 25, Jan. 1933, pages 49-53. Information and performance of several classes of coatings are discussed under headings: requirements for satisfactory pipe-line coatings, oil paints, bituminous "cut-backs," asphalt emulsions, greases, lacquers and synthetic resins, molten bitumens, pipe-line wrappers, bituminous mastics, cement coatings and vitreous enamels. MEH (4)

SEA WATER CANNOT CORRODE -ILLIUM-

For three hundred and seventy-one days samples of ten different alloys all presumably corrosion resistant, were left in wooden trays on the seashore of Burgess Isle, Bokeelia, Florida, so that they were periodically covered by tide water and subsequently exposed to the sun and air. This periodic immersion in sea water and subsequent exposure to the atmosphere is a severe service for any material, as is clearly indicated by the appearance of the ten samples in the unretouched photographs. Below the photograph of each sample tested is its loss in weight in milligrams per square centimeter for the entire period of the test (over one year).

BURGESS-PARR ILLIUM
Heads the List

with a loss of only 1.8 mg. per sq. cm. per year, and without a visible sign of corrosion. The other alloys, and their respective positions in the series of photographs are:

2. 18-8 Stainless Steel
3. High Nickel, Chromium, Silicon, Iron Alloy
4. Chromium, Nickel, Copper, Molybdenum Stainless Steel
5. Nickel (58%), Molybdenum, Iron, Manganese Alloy
6. 14% Chromium Stainless Steel
7. 18-8 Stainless Steel
8. 14% Chromium Stainless Steel
9. Phosphor Bronze
10. Copper, Nickel, Tin, Silicon Alloy.

In sea water or in acids, under any condition of severe corrosion, Burgess-Parr Illium leads the field in resistivity.

Your corrosion problems can be solved with Illium. Write to us about them.

These photographs were taken under identical conditions and were not retouched or manipulated in any way.

BURGESS-PARR COMPANY
DIVISION OF C.F. BURGESS LABORATORIES INC.
MOLINE, ILLINOIS

You know what Corrosion does

You have seen plenty evidence of what corrosion of one kind or another has done. It has destroyed metals, equipment, and machinery. It has run up maintenance expenses, delayed production, added gray hairs to the Production Manager's head, caused mechanical failure at crucial moments, and added a world of troubles to a pack already filled.

You may have figured it as a part of the business; that Corrosion was like the weather, something to talk about but mighty little could be done about it. But perhaps something can be done, that you may not have heard about.

We know what to do about it

It has been our business, for the past twenty years, to do something about Corrosion, especially handling in one form or another, the corrosive chemicals used in Industry. That is our specialty—we like it, and are well acquainted with the peculiarities and odd behavior of corrosives under the varying factors of hydrogen ion concentration, temperature, dilution, salts in solution or suspension, aeration, velocity and similar conditions.

Corrosion may be causing you some unnecessary trouble. Give a little thought to the corrosion conditions in your plant—and then call in a Duriron Company representative to talk it over with you. He isn't a "high pressure" salesman—he is a trained engineer, service man, if you please, who has the engineering slant on things. If any Duriron Company Products will handle your case, that's fine. If not, he will tell you so just as quickly.

Right now is a good time, too, before production problems become so pressing that you can't give the proper consideration to corrosion prevention.

DURIRON
DURICHLOR
DURIMET
DURCO ALLOY STEELS

THE DURIRON COMPANY, Inc.
432 NORTH FINDLAY STREET DAYTON, OHIO

1 **Notes on a Distribution System Soil Survey.** A. B. Allyne. *Gas Age-Record*, Vol. 70, Aug. 27, 1932, pages 207-208, 219. A soil survey of the entire transmission and distribution system of the Southern Counties Gas Co., Los Angeles, Calif., was started about one year ago (*Metals & Alloys*, Vol. 3 July 1932, page MA 201) and is now 85% completed. The results to date have permitted the tentative classification of soils into certain groups of relative corrosivity and the specification of mains and services for these soils. This classification follows:

Class of Soil	Descriptive Terms	Rod Readings Ohms-Cms.	Estimated Life of Bare Steel Pipe. Years	Specifications for Mains	Specifications for Service
1	Excellent	10,000-6,000	25 or more	Steel pipe with no protective coating.	Steel-wrapped.
2	Good	6,000-4,500	17-25	Steel with a protective coating, the cost of which will not constitute more than 10% of the entire cost of the job.	Steel-wrapped.
3	Fair	4,500-2,000	10-17	Cast Fe, Cu, or heavily protected steel, depending on local conditions. If steel, cost of protective coating shall not exceed 20% of the entire cost of the job.	Cu tubing with soldered couplings and stream-line fittings.
4	Bad	0-2,000	0-10	Cast Fe or Cu. No steel installed in this classification of soil.	Same as Class 3.

Shepard soil rods were used. Of the many inspections of pipe and coatings made by this company since the use of the rods, none has been found at which the Shepard readings were below 2000, that the pipe and the coating itself were not in a state of deterioration. To determine the seasonal change in rod readings 149 test locations have been selected at which readings will be taken once a month for a year. The total cost of the survey will be approximately $4000 with 20,000 readings on record. VVK (4)

4 **Formation of Impurities in Municipal Gas Lines and their Effect on the Corrosion of such Systems. (Nachträgliche Bildung von Verunreinigungen im Stadtgase und ihre Folgen auf das Rohrnetz.)** Nauss. *Gas und Wasserfach*, Vol. 75, Dec. 10, 1932, pages 985-988. Discussion of various types of corrosion in gas lines and methods of their avoidance. GN (4)

Maintenance Costs of Pipe Systems. (Ueber die Rohrnetzunterhaltungskosten, deren Höhe und Verteilung.) H. Brückner & W. Ludewig. *Gas und Wasserfach*. Vol. 75, June 18, 1932, pages 509-511. Summary of results of questionnaire sent to 35 German gas works. Of interest to the metallurgist are the cost data given on repair of line systems due to corrosion. GN (4)

5 **Methods for Estimating Corrosiveness of Acid Soils in Contact with Iron and Steel Pipe.** I. A. Denison. *Oil & Gas Journal*, Vol. 31, Sept. 29, 1932, pages 83-87. A general relationship (increase of corrosion with increase of total acidity) is found with well developed humid soils such as occur in the eastern part of the U. S. This does not apply to the alkaline soils in the arid or semiarid regions of the middle and far west or to marshes and soils which have been contaminated by material from some external source such as overflow waters from oil wells. Alternative methods for determining total acidity of soils are given. This study is based on the 8-year results of the Bureau of Standards Soil Corrosion Investigation. VVK (4)

6 **Tarnish-Resistant Silver Alloys.** K. W. Ray & W. N. Baker. *Industrial & Engineering Chemistry*, Vol. 24, July 1932, pages 778-782. The Ag-Zn-Al system containing from 75 to 100% Ag is investigated. Several alloys of Ag with Cr, Zn, Al, Be, Cu, Si, Sn, and Ba as binary, ternary and quaternary alloys are studied. An attempt is made to nitride the various alloys with gaseous ammonia at a somewhat elevated temperature in the hope that a tarnish-resistant case will be formed. 12 references. MEH (4)

Is the Application of Trisodium Phosphate for Boiler Water Conditioning Detrimental? (Ist die Anwendung von Trinatriumphosphat zur Speisewasserpflege unschädlich?) P. Robert. *Schweizerische Technische Zeitschrift*, Vol. 29, Aug. 18, 1932, pages 497-503; Aug. 25, 1932, pages 513-517. Discusses cases of corrosion and their causes in a boiler due to addition of sodium phosphate to feed water. The cases were studied at various pressures, temperatures, durations, 7 and concentrations of sodium phosphate. A special testing apparatus is described in which limiting values of factors affecting corrosion are to be determined, as composition, temperature and circulation velocity of water and boiler materials. GN (4)

How Cadmium Resists Aqueous Solutions. B. E. Roetheli, A. J. Franz & B. L. McKusick. *Metal Industry N. Y.*, Vol. 30, Sept. 1932, pages 361-363. Contains bibliography. Partially paraffin coated Cd specimens were immersed in a continually flowing, uniformly agitated, aerated corroding medium whose pH was controlled by additions of HCl or of NaOH. When the pH is below 5.9, the corrosion is inversely proportional to the pH. The probable safe minimum pH of oxygenated solutions in which cadmium is to be immersed is 6. At pH greater than 5.29 8 colored corrosion products result. PRK (4)

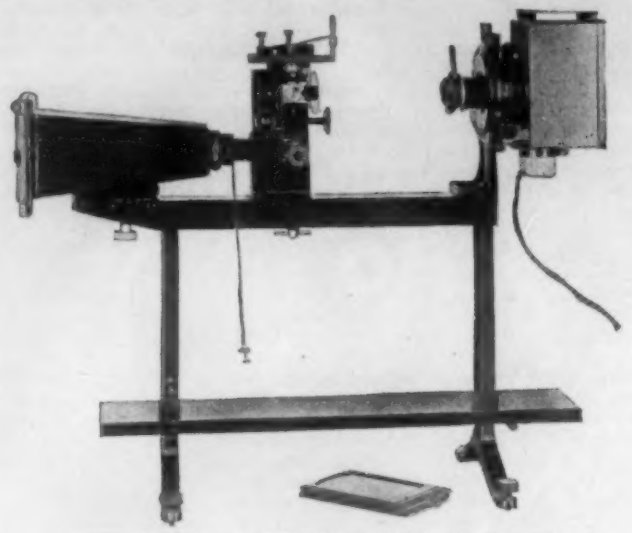
Masked Hydrogen Embrittlement in Brittle Copper Wires. (Verdeckte Wasserstoffkrankheit an brüchigen Kupferdrähten.) C. Schaarwächter. *Zeitschrift für Metallkunde*, Vol. 24, Sept. 1932, pages 234-236. Includes discussion. Paper before Deutsche Gesellschaft für Metallkunde, June 26, 1932. Laboratory experiments on H annealing of Cu containing Cu_2O, with subsequent heating in air, show presence of 3 zones: innermost containing Cu_2O, next free from Cu_2O owing to reducing action of H but containing hair-cracks formed by reduction of Cu_2O and formation of water vapor; and outermost showing penetration of Cu_2O along hair-cracks. Heating in CO instead of H gives similar results. Brittleness of such Cu is ascribed to penetration of Cu_2O along hair-cracks. In practice similar 9 zones occur but hair-cracks cannot be found. Mechanism of embrittlement in practice, where hair-cracks cannot be found (*"verdeckte Wasserstoffkrankheit"*), is same as that which obtains in laboratory experiments with H. RFM (4)

Eloxal Process. (Das Eloxalverfahren.) Hans Schmitt. *Metallwirtschaft*, Vol. 11, Dec. 16, 1932, pages 689-690. Process consists of producing an oxide coating on surface of articles made of Al or Al alloys by electrolytic means. Electrolyte consists of an oxalic acid solution with addition of a strong mineral acid. By proper choice of concentration of solution, temperature, current density and voltage, structure and properties of oxide coating can be varied to suit several purposes. For wire, strip and foil an elastic film can be produced which will withstand bending and has good electrical insulating properties. If desired it can be 10 made sufficiently porous to absorb insulating or Bakelite varnish, resulting in high electrical resistance. A very hard coating can be produced which is used on screws, valves, gas cocks and hose couplings. Another application is for vessels which are to resist corrosion of fruit juices and wine. For this purpose vessels are sometimes impregnated with linseed oil and then baked. This type of coating has no effect on flavor of liquids. CEM (4)

for

Restricted Budgets

There is real economy in the purchase of the B&L Routine Metallographic Equipment S I *right now!* Here is a handy compact instrument that does the highest grade of work—at a price that fits it into even the most restricted budget.



The present day interest in alloys of all kinds and the demand for the highest quality in finished products, seriously handicaps the organization which does not have metallographic equipment. The S I enables the forward looking company to meet this demand at a price in keeping with today's budgets.

In this instrument are found such advantages as the permanently aligned optical system, fine adjustment which carries only the objective, and the direct illuminating beam from source to vertical illuminator. Such features make the finest work possible and give an accuracy and efficiency of performance heretofore found only in the most expensive equipment.

"Optical Instruments for Examining and Analyzing Metals" will be gladly sent upon receipt of the coupon.

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Introduction to Practical Metallography. (Einführung in die praktische Metallographie.) (No. 76 in Breitenstein's Repetitorien.) B. GARRE. Johann Barth Verlag, Leipzig, 1932. Board cover, 5x7¼ inches, 51 pages. Price 4.20 R.M.
Typical equilibrium diagrams are shown with diagrammatic black and white sketches of the structures and grain size of the alloys of various compositions and heat-treatment inserted, and with physical property charts below the diagrams. As the eye runs down the line for a given composition, one grasps the equilibrium relations, the structure, and the properties together in quite effective fashion. The scheme should be of distinct value as a method of instruction.

The scope of the pamphlet is not wide, as it covers only steel and cast Fe with a very little on alloy steels, Cu Ni, Sb Sn, Pb Sb, Al Mg, Al Zn, Cu-Cu_2O, brass, bronze, Al Si, and a little on duralumin, but it should serve excellently as a first introduction to metallography. H. W. Gillett (5a)-B-

6

Alloys of Gallium with Zinc, Cadmium, Mercury, Tin, Lead, Bismuth and Aluminum. (Ueber die Legierungen des Galliums, mit Zn, Cd, Hg, Sn, Pb, Bi and Al.) N. A. PUSCHIN, S. STEPANOVIC & V. STAJIC. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 209, Dec. 1932, pages 329-334. Constitutional diagrams of above alloys were developed. It was found that Ga forms with Cd, Hg, Bi, and Pb 2 immiscible liquid layers, and with Zn and Sn eutectic mixtures. 3 compounds are formed with Al, namely, Ga_2Al, GaAl and $GaAl_2$. Maximum solubility of Ga in molten Pb is 5%, in Bi 11%, in Cd 12-13%. It is practically insoluble in liquid Hg at low temperatures. Ha (5a)

7

The Constitution of the Copper-Silver Series of Alloys Examined Thermodynamically. F. H. JEFFERY. *Transactions Faraday Society.* Vol. 28, Sept. 1932, pages 705-707. The liquid solution consists of monatomic molecules of Cu and of Ag, the solid solutions consist of monatomic molecules of Ag dissolved in monatomic molecules of Cu, and of monatomic molecules of Cu dissolved in monatomic molecules of Ag. The calculations were based on the equilibrium diagrams of Stockdale for the solidus and of Heycock and Neville for the liquidus. PRK (5a)

8

The Lead-rich Alloys of the System Lead-Antimony Examined Thermodynamically. F. H. JEFFERY. *Transactions Faraday Society.* Vol. 28, July 1932, pages 567-569. Based on the data of Schumacher and Bouton, thermodynamic reasoning shows that Sb combines with liquid Pb to form Pb_2Sb, dissolving in excess liquid Pb. Pb_2Sb also forms a solid solution in Pb, accounting for the hardening effect. X-ray analysis differs from thermodynamic analysis in this system, the former giving no evidence of compound formation. PRK (5a)

9

Physical Chemistry. The Phase Rule. (Lehrbuch der physikalischen Chemie. Die Phasenlehre.) Vol. 4. KARL JELLINEK. Ferdinand Enke Verlag Stuttgart, 1933. Paper, 6½x10 inches, pages 625-890. Price 26 RM. This volume contains a few pages on concentrated solutions, completing the treatment of that subject in the previous volume, but the bulk of it deals with the phase rule. A couple of pages are devoted to the metallographic examination of alloys and a few of the typical equilibrium diagrams shown are for alloys. The author deals with general principles, using individual diagrams only as examples, and does not attempt to bring together the latest information on alloy systems. For most of those cited Landolt-Bornstein is given as the reference and corrections based on modern X-ray information are not given. Nor are methods of establishing the alloy diagrams given more than casual mention. Hence, the book is of only secondary value from the point of view of direct metallurgical information.

From that of explanation of principles, it is of primary value. The treatment of ternary diagrams, of isotherms of solid models and of ways of handling quaternary and more complex system, is helpful for reference. It is one of the most comprehensive text books on the subject. H. W. Gillett (5a)-B-

10

Application of Binary and Ternary Equilibrium Diagrams to the Study of Effect of Sulphur in Steels and Cast Irons. (Application des Diagrammes Binaires et Ternaires a l'Etude de l'Influence du Soufre sur les Aciers et les Fontes.) J. R. MARECHAL. *La Fonderie Belge,* Vol. 2, Apr. 1932, pages 54-62. See *Metals & Alloys,* Vol. 4, Jan. 1933, page MA 4. FR (5a)

6

Division of the Iron-Vanadium-Oxygen System into Some of Its Constituent Binary and Ternary Systems. C. H. MATHEWSON, E. SPIRE & C. H. SAMANS. *Transactions American Society for Steel Treating,* Vol. 20, Oct. 1932, pages 357-384. Authors have studied briquetted and sintered mixtures prepared in vacuo and find that there are 4 oxide phases which may appear separately in equilibrium with Fe, FeO, FeV_2O_4, V_2O_3 and V_2O_2. FeV_2O_4 is an Fe-V spinel sufficiently soluble in Fe to form well crystallized inclusions. Other oxides except FeO are practically insoluble in Fe so that they make satisfactory crucible materials for preparing clean metal. Several of binary and ternary systems have been examined by X-ray and metallographic methods. System FeO-FeV_2O_4 is characterized by an eutectic of approximately 18 mols of FeO and 1 mol of FeV_2O_4. Crystal structure of V_2O_2 is similar to FeO. There is no lower oxide of V and this oxide reduces FeO. Acicular structures similar to Widmanstätten structure are observed in V-O alloys of suitable composition and presumably represent separation of V from the solid solution. 15 references. WLC (5a)

7

Solubility of Zinc and Aluminum in Magnesium. Correspondence from ED. MAURER & W. BISCHOF. *Metal Progress,* Vol. 22, July 1932, pages 54-55. Zn-Mg and Mg-Al equilibrium diagrams based on X-ray analysis are presented. WLC (5a)

Copper Tin Compound in Babbitt. GEORGE A. NELSON. *Metals & Alloys,* Vol. 3, July 1932, pages 168-170. The author presents the results of a study of intermetallic compounds present in tin base babbitts. Etching technique for good study of these crystals is given with stereoscopic micrographs. CuSn is in the form of an hexagonal shaped needle of considerable length usually. SbSn appears to initially crystallize on the particles of CuSn. Increase in Cu results in an increase in the size and decrease in the number of SbSn crystals. Less than 2.5% Cu results in rapid depletion of available Cu and the star shaped crystals cannot be formed. CuSn is softer than SbSn. When the six pointed stars described are present points of CuSn crystals penetrate matrix to a considerable distance. WLC (5a)

8

An Investigation of Al-rich Al-Fe-Si Alloys. HIDEO NISHIMURA. *Tetsu to Hagane,* Vol. 18, Aug. 1932, pages 849-860. Constitution of alloys of Al, Fe, and Si from 0 to 30% of Si and from 0 to 30% of Fe has been investigated using thermal and microscopic analyses. 7 section diagrams whose Fe contents are 1, 3, 2, 4, 10, 15, 20, 25, and 32% of Fe respectively has been studied and from these sections an equilibrium diagram of this system in that composition range has been determined. In this diagram there exist 5 primary crystallization surfaces of Al, $FeAl_3$, $FeAl_3$, $FeSi_2$ (an unknown phase) and Si, the binary reaction curves, Liquid $\rightleftarrows$ Al + $FeAl_3$, Liquid $\rightleftarrows$ Al + $FeAl_3$. $FeSi_2$, Liquid + $FeAl_3$ $\rightleftarrows$ $FeAl_3$ · $FeSi_2$, and Liquid $\rightleftarrows$ $FeAl_3$ · $FeSi_2$ + Si, and 3 invariant points, Liquid + $FeAl_3$ $\rightleftarrows$ $FeAl_3$. $FeSi_2$ + Al at 615° C., Liquid $\rightleftarrows$ Al + Si at 578° C., and Liquid + X $\rightleftarrows$ $FeAl_3$ + $FeAl_3$: $FeSi_2$. Ternary compound which has hitherto been called X, has been proved to be $FeAl_3$. $FeSi_2$ microscopically. TS (5a)

9

The System Mg-Al-Cu (Contribution a l'étude du système ternaire magnésium-aluminium-cuivre). A. PORTEVIN & P. BASTIEN. *Comptes Rendus,* Vol. 195, Aug. 17, 1932, pages 441-443. That part of ternary diagram corresponding to triangle Mg-Mg_4Al_3-Mg_2Cu was investigated. System was studied by means of cooling curves, micrographic examination and certain physical properties. Existence of ternary compound $Mg_2Al_3Cu_2$ is indicated. Phase diagrams are given. OWE (5a)

10

Introduction to Metallography. (Einführung in die Metallographie.) PAUL GOERENS. 6th Edition. Wilhelm Knapp, Hall a.d. Saale, 1932. Paper, 6¼x9¼ inches, 392 pages. Price 15.50 RM. The 3 parts are: I. Theoretical, pages 1-145; II. Practical, pages 146-276; III. Metallography of Technical Ferrous Materials, pages 277-374.

Part I discusses the pure metals, considering thermal changes, crystallization and microstructure. Then follows the discussion of binary alloys classified as to types, with illustrations from actual equilibrium diagrams. Great care has been taken in the application of the phase rule, the exact boundaries of different fields, the relative amounts of the phases present at different concentrations and temperatures. The treatment of ternary systems is brief, only about 6 pages. Cu-Sn and Cu-Zn alloys are treated in considerable detail. Ferrous alloys are discussed, pages 84-145, in considerable detail, giving the Fe-C and 20 other binary alloys of Fe. In general, these diagrams are brought up to include recent data, but this is not always the case; for example, in the Fe-Mo system the findings of Takei and Murakami and the more recent work by Sykes have not been included. Likewise in the Fe-W system some of the latest findings have not been included.

The second part (Praktischer Teil) really deals with experimental equipment and methods used in metallographic work. The subjects include furnaces, pyrometers, dilatometers, X-ray equipment and microscopy. Only about 6 pages have been given to X-rays, which is much less than the modern importance of the subject would seem to justify. On the other hand, it seems that too much space and too many details have been given for special microscopes.

Part III, as the title suggests, deals with technical ferrous metallography and covers such subjects as ingots and ingot structures, wrought Fe, cast Fe, plain C steels, alloy steels, microstructures, forging strains, stress lines, etc.

The text is well illustrated with 485 figures, and the references to original literature are quite extensive. The care and detail with which some of the material is presented becomes almost a weakness. Four excellent photomicrographs in color suggest the possibilities of developments along this line.

This text is suitable for beginners and those who have limited knowledge of metallography, but who read German. Oscar E. Harder (5a)-B-

Practical Microscopical Metallurgy. R. H. GREAVES & H. WRIGHTON. 2nd Edition. D. Van Nostrand, New York, 1933. Cloth, 6¼x10 inches, 256 pages. Price $6.00. The number of pages has been doubled, and the number of illustrations increased 40% over the first edition which appeared in 1924. The book has been greatly improved over the first edition in that its scope is materially increased. The first edition was a good discussion of microscopic structures and the technique of showing them. This edition includes all that and also tells a good deal about what the structures mean in terms of the engineering utility of the alloys. It has grown up from a metallographer's book to a metallurgist's book.

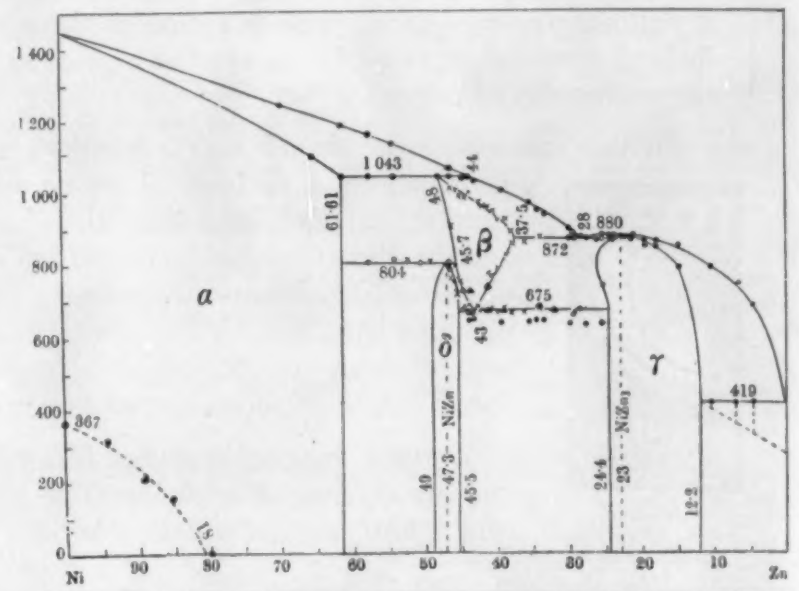
Some of the features that the present edition deals with fairly extensively, which were omitted or far less thoroughly covered in the first edition are: microstructure and low-power metallography, deep etching, the gamma loop in alloy steels, precipitation-hardening systems, high tensile structural steels, molybdenum steels, and corrosion and heat-resistant steels.

In the non-ferrous field, the effect of Ag and of Si in Cu, of Al in brass, the aluminum alloy systems, lead alloys and bearing metals, are among the subjects more thoroughly dealt with.

It is a well-written, authoritative volume, well worth a place on the metallurgist's book shelves, and a place close to his elbow. H. W. Gillett (5a)-B-

New Macroscopic Method of Detecting the Sulphur Impurities in Steel. KAROLINA KATZOWNA. *Przemysl Chemiczny*, Vol. 15, Dec. 1931, pages 383-390. (In Polish). S and P inclusions in steel cannot be exactly distinguished by methods of Baumann, and method of van Royen and Ammermann, because there is no distinct difference in reaction of silver salts with H_2S and PH_3. Method of Feigl and Niessner is troublesome in metallographic practice. Cu salts with H_2S give a black deposit, yet they react more slowly with phosphine. Still greater difference in velocity of reaction is presented by the Pb salts. The celloidin photographic paper is treated with $Na_2S_2O_3$ in order to remove the Ag salt. Paper is subsequently washed with water, immersed in 10% solution of Pb nitrate for 5 min., and treated with 2% H_2SO_4 for 2 min. In order to remove the adherent deposit of $PbSO_4$, the paper is washed out and wiped off with cotton. Before use the paper is immersed in 5% H_2SO_4 for 1 min., and then pressed to the polished and degreased surface of specimen for 5 min., whereupon paper must be carefully washed. Time of pressing is too short to produce any perceptible spots of P. Result thus obtained is then picture of only S inclusions in steel. 10 references. ZJ (5a)

Kinetics of Transformations During the Hardening of Steel. (Zur Kinetik der Umwandlungen bei der Stahlhärtung.) F. WEVER. *Die Naturwissenschaften*, Vol. 20, May 27, 1932, pages 412-416. Magnetic investigation made into decomposition of austenite in relation to temperature and composition. Small needles (5 mm. diameter, 200 mm. long) of an 0.35% C, 0.86% Cr, 4.04% Ni steel provided with a Cu-shell were heated to 860°C., cooled down to and held at testing temperature. Amount of ferro-magnetic crystal phases precipitating from disintegrating austenite were measured with an astatic magnometer. Results are summarized as follows: austenite transformation takes place in 3 different temperature stages according to different laws. In range of first or pearlite transformation, i.e. at 500°-560°C., diffusion velocity of C is sufficiently great to warrant a complete decomposition of austenite into ferrite low in C and into Fe carbide. In second temperature range an intermediary state occurs yet unknown. This state however shows no stability and changes to ferrite and cementite. In third range, i.e. below 270°C., austenite is spontaneously converted into tetragonal martensite, which, at a low rate, further decomposes into ferrite and highly dispersed carbide. The phases are shown in micro-structures. EF (5a)



Martensite Crystallization Studied by a Moving-picture Camera. (Die Martensitkristallisation im Filmbild.) H. J. WIESTER. *Zeitschrift für Metallkunde*, Vol. 24, Nov. 1932, pages 276-277. Paper before Deutsche Gesellschaft für Metallkunde, June 26. 1932. Simple C steel was quenched from austenite range to 100°C. and formation of martensite studied by photomicrographs taken at rate of 20 per second in a moving-picture camera. First photomicrographs showed pure austenite, and formation of martensite with time observed. A martensite needle forms fully in less than 1/20 of a second, at temperatures of 100° C. and lower. Illustrated by 4 successive photomicrographs. RFM (5a)

The System Ferrous Oxide-Silica. GAICHI YAMADA. *Suiyokai-Shi* (Transactions Mining & Metallurgical Alumni Association, Kyoto Imperial University, Japan), Vol. 6, 1931, pages 519-543, 561-570; *Memoirs College of Engineering, Kyoto Imperial University*, Japan, Vol. 6, 1931, pages 251-274. FeO of 84-90% purity was prepared by reduction of Kahlbaum's Fe_2O_3 in a gas-mixture of CO and CO_2 at a certain temperature from 800° to 1000°C., relation between composition of gas and reducing temperature being inferred from Fe-FeO curve in the Matsubara's Fe-O_2-C diagram. FeO thus prepared and Merck's SiO_2 were melted in a platinum crucible in a purified nitrogen atmosphere, and thermal analysis was carried out, by means of inverse-rate method using Pt/Pt-Rh couple, in the range of silica contents of less than 45.5%, which corresponds to $FeO{\cdot}SiO_2$. After the thermal analysis the micro-structure was observed. From these experiments, equilibrium diagram of FeO-SiO_2 system was determined and following results were deduced: Melting point of FeO is 1378°C. Eutectic of FeO and $2FeO{\cdot}SiO_2$ exists at composition of 23.5% SiO_2 and at temperature of 1150°C. $2FeO{\cdot}SiO_2$ is unstable at higher temperatures than 1360°C., at which it decomposes to 2 melts. At composition of 39.5% SiO_2 at 1115°C. another eutectic probably of $2FeO{\cdot}SiO_2$ and $FeO{\cdot}SiO_2$ occurs, but existence of $FeO{\cdot}SiO_2$ is not certain. ST (5a)

Method of Preparation of Lead and Lead Alloy Cable Sheath for Microscopic Examination. W. H. BASSETT, JR. & C. J. SNYDER. *Proceedings American Society for Testing Materials*, Vol. 32, Pt. 2, 1932, pages 558-575. Includes discussion. Pb and Pb alloy cable sheaths contain irregularities in grain structure that are best examined microscopically. Where microtome is too expensive, authors have obtained satisfactory results by filing and polishing. Polishing must be done by hand using a circular motion on emery paper and broadcloth backed by plate glass. Gasoline is used as a lubricant and cleaning medium. Different etching reagents are recommended for various alloys. Specimens should be examined by vertical light. Suitable magnifications for Pb are 5 to 75 diameters, for Pb-Sn alloys 20 to 200 diameters, and for Pb-Sb alloys 50 to 500 diameters. Photographs are included. VVK (5a)

Metallography. Report of A.S.T.M. Committee E-4. C. H. DAVIS, Chairman. *Proceedings American Society for Testing Materials*, Vol. 32, Pt. 1, 1932, pages 507-509. Progress reports of subcommittees. VVK (5a)

On the Equilibrium Diagram of the Binary System, Nickel and Zinc. KANZI TAMARU. *Kinzoku no Kenkyu* (In Japanese), Dec. 1932, pages 511-526; *Science Reports Tohoku Imperial University*, Vol. 21, 1932, pages 344-363. Equilibrium diagram of system Ni-Zn was investigated by total and differential thermal analyses, electric resistance and differential dilatometric measurements in nitrogen atmosphere. Effect of Zn upon magnetic transformation of Ni was also studied. Liquidus obtained is nearly same as that of Tafel. α solid solution extends to 61.61% Ni at 1403° C. Range of β solid solution on Zn side reaches 37.5% Ni at temperature of eutectic reaction; eutectoid transformation of β solid solution extends from 44.74 to 24.4% Ni at 675° C. This transformation takes place at about 700° C. on heating and at 640° C. on cooling, so that mean temperature 675° C. is adopted. Compound NiZn or δ solid solution has a solubility on both sides and is found to be homogeneous between 49 and 44.74% Ni. Reaction $\alpha + \beta \rightleftarrows \delta$ takes place at 804° C. Compound $NiZn_3$ has also a solubility of 1.4% Ni on Ni side. Liquidus and eutectic horizontal near $NiZn_3$ are distinctly found by differential thermal analysis, sensibility of which is 25°/1000 for 1 mm. scale deflection, and hence Bauer and Hansen's view regarding peritectic reaction is not valid. According to X-ray analysis, α-solid solution has face-centered cubic lattice, β and δ, hexagonal and γ, cubic which is very similar to that of α-manganese. KT (5a)

Graphite in Cast Iron. (Le Graphite dans la Fonte.) A. ALLISON. *Bulletin de l'Association Technique de Fonderie*, Vol. 5, Mar. 1932, pages 82-83. A summarized translation. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 34. FR (5a)

On the Grain Refinement of Copper-rich Alloys by Peritectic Reaction. J. ASATO. *Kinzoku no Kenkyu*, Japan, Sept. 1932, pages 392-411. It is well known that grain size of Al bronze becomes very fine when Fe is added, but there has been no clear explanation of it. Author found, after studying Cu-Fe, Cu-Zn-Fe, Cu-Sn-Fe, Cu-Mn-Fe, Cu-Ni-Fe and Cu-Al-Fe alloys, that grain refinement is closely related to peritectic reaction between Cu and Fe, and that Fe may be replaced by Co. In each case grain size decreased to 1/1000 ~ 1/10,000 when Fe was added over peritectic point. Effects of cooling velocity and casting temperature upon grain size were also investigated but no marked effects were observed in these cases. KT (5a)

The Constitution of Copper-Tin-Lead System. B. BLUMENTHAL. *Metals & Alloys*, Vol. 3, Aug. 1932, pages 181-182. Correlated abstract. Cu-Sn-Pb alloys are discussed in light of several constitutional diagrams which are shown. Compositions and services for which these bearing alloys are useful are referred to in 9 references. WLC (5a)

Structure of Heat Treated Low Carbon Steel. WELTON J. CROOK & EDMUND C. BABSON. *Metals & Alloys*, Vol. 3, Aug. 1932, pages 183-184. Discusses results of a study of structural changes in 0.20% C steel when quenched at temperatures from 1300° up to 1650° F. This steel gives martensitic areas when quenched between Ac_1 and about 1420° F, which martensite reacts toward drawing normally passing through troostite, sorbite, to a spheroidized pearlite. When quenched between 1420° F. and Ac_3 a troosto-martensite is obtained and when quenched just above Ac_3, 1550° F. an almost entirely troostic structure is obtained which does not change with drawing except for a gradual growth of cementite particles and elimination of acicular structure. 6 references. WLC (5a)

Investigations on the Transformations in Solid Phase of Copper-Gold System. (Untersuchungen über die Umwandlungen in fester Phase beim System Kupfer-Gold). M. LEBLANC & G. WEHNER. *Annalen der Physik*, Series 5, Vol. 14, Aug. 1932, pages 481-509. Arrangement is described for casting alloys of high melting point in vacuum and measuring conductivity of cast specimens up to 500° C. While pure Cu showed a secondary electric conductivity depending on grain size, this was not observed in Au. Conductivities of alloys when quenched from high temperatures formed U-shaped curve as is typical for solid solutions. Diagram of conductivity isotherms was developed for tempered alloys below 450° C. showing 3 maxima which mean existence of compounds Cu_3Au, Cu_3Au_2 and CuAu. Ha (5a)

Photomicrographs at Low Magnification. JAMES OSBORN LORD. *Transactions American Society for Steel Treating*, Vol. 20, July 1932, pages 1-26. Author discusses methods of illumination, set-up and apparatus for making low magnification photographs of flat subjects and those with varying degrees of relief. WLC (5a)

Relation of Iron-nitride to Plastic Flow and to the Fry Etch. C. W. MACGREGOR & F. R. HENSEL. *Journal of Rheology*, Vol. 3, Jan. 1932, pages 37-52; extended abstract, *Metals & Alloys*, Vol. 3, May 1932, pages 127-128. Discusses utility of Fry reagent in showing plastic flow in materials containing N as iron nitride. WLC (5a)

Structure & X-Ray Analysis (5b)

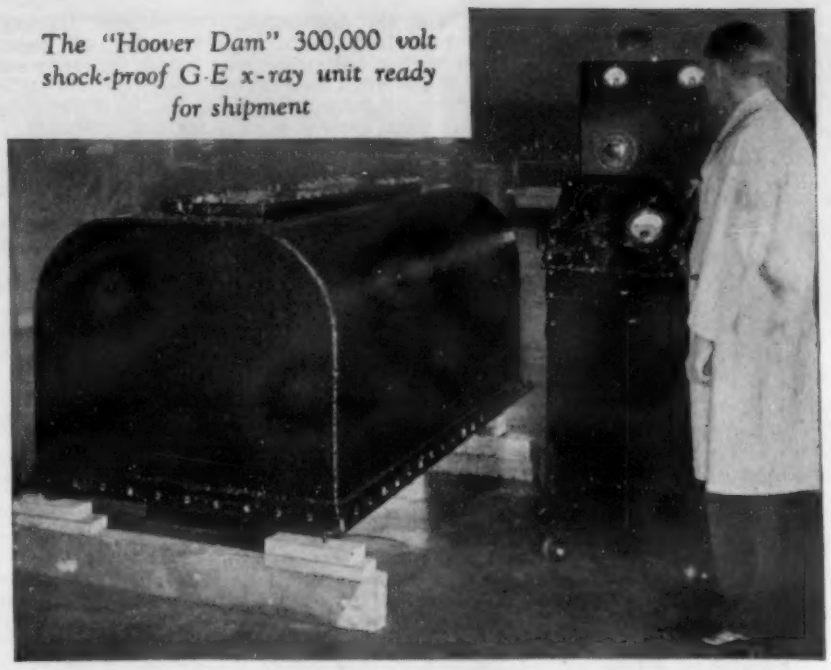
Applied X-Rays. GEORGE L. CLARK. 2nd Edition. McGraw-Hill Book Co., New York, 1932. Cloth, 6x9 inches, 470 pages. Price $5.00. This popular book, first appearing 6 years ago, is now offered to the public in a new and enlarged edition, in form and treatment departing little from the first edition. This new edition discusses the latest developments in the field of applied X-rays and also much of the physics basic to such developments. It includes discussions of X-ray tubes and high tension equipment; X-ray spectra; absorption and scattering of X-rays; radiography; physical, chemical, and biological effects; crystallography; diffraction; X-ray diffraction methods of analysis; interpretation of diffraction patterns; results of crystal analysis; structure of alloys; structure of compounds; practical application of X-rays in many fields; colloids; organic substances. In the preface the author disclaims any intention of writing a handbook for the complete and precise determination by experts of wave-lengths or crystal structure. He wishes the book to serve as a "missionary," to depict the "promise for the layman in industry and in the class room" in the application of X-rays as a new tool for industry. The book covers a large field, with a surprising number of examples of the practical application of X-rays. The sections on X-rays are fairly well balanced, though occasionally lack of balance is evident. There seems to be little use in such a prolonged treatment of X-ray line spectra (Chapter V) for a book of this sort, whereas a bit more detail with respect to new X-ray tubes of foreign manufacture would be welcome. Also a diagram of intensity versus wave-length for a tube operated above the voltage at which the characteristic radiation appears would be useful to a student since this is the normal condition for most diffraction work.

The treatment of X-ray methods and crystallography is less satisfactory. Several of the familiar methods are described, but in no case is sufficient information given to enable the student to solve a diffraction photogram. A number of omissions seriously decrease the usefulness of the book. Thus, the Bragg focusing principle should have been briefly explained; the high-precision methods for determining lattice spacing developed by Sachs and others should have been given; the Davey-Wilson orientation camera should have been included. It is a bit surprising that no mention is made of cameras for diffraction studies at high and low temperatures. Omissions are also evident in the crystallographic sections. There is only a bare mention of the stereographic projection though this is probably the most useful graphical method in the study of crystals. Also the face-pole figure developed by Wever is not mentioned, though this is the only really satisfactory method for the representation of fiber structures. The well-known Hall-Davey charts for the solution of powder photograms should have been given. The general usefulness of "four-point" and "six-point" fiber patterns must be doubted, for these can be only a partial representation of fiber structure. The introduction of space-group symbols with no explanation is of little use. These sections, however, are better than the corresponding sections in the previous edition.

The sections on the applications of X-rays make interesting reading. The imagination which has led the author and many others to apply X-ray diffraction methods in a wide field will doubtless in time yield important practical results, and in a small measure has already done so. The reviewer is of the opinion, however, that a too great enthusiasm for partial results has somewhat prejudiced the practical man, that in many cases research effort could be better expended in an attempt to explain the X-ray results obtained rather than to hurry into practical application.

The structural analogies which have been discovered in alloys (Chapter XV) are well treated. The table of the structures of elements (pages 188-189) is useful. But in many ways this section is guilty of over-statements and inaccuracies. The usefulness of the book to industrial metallurgists will depend upon the validity of its statements, and misstatements must be pointed out. The metallurgist will be surprised to read that inclusions in metals may be analyzed by X-rays without dissolving the metal (page 253), that X-rays have made possible a "rationally scientific explanation . . . . . of the properties of various alloy steels in terms of ultimate constitution and structure" (page 303), that as a result of the work of Graf and Glocker and of Tammann "a complete picture of corrosion and resistant mechanism is afforded—all based on the interpretations of X-ray diffraction patterns" (page 305), that the thermal evidence for intermetallic compound formation is (always) a maximum "in the melting point curve" (page 281), that "the interstitial type of solid solution is usually unstable" (page 290). Some important omissions are evident in this section of the book. The newer methods for detecting and measuring internal strain (Sachs, Wever, and Regler) are not mentioned, but considerable attention is given to radial asterism though the use of radial asterism as a quantitative measure of strain is beset with difficulties and uncertainties. The new work of Cameron (1932) on particle size is not mentioned, and the precision of particle size determination is somewhat misrepresented. The structure of Fe_3C proposed by Hendricks should have been mentioned. Certain sections are inadequate and somewhat inaccurate, such as that on age-hardening (page 302), that on the determination of orientations (page 351), that on passive iron—for which there are now results from electron diffraction research, and that on martensite in which there is no mention of the important work of Kurdjumow and Sachs. The book would be more useful if a far greater number of references to sources had been made, and if an author index had been included.

The book in its present form represents essentially an account of what has been attempted by X-rays. In this sense it is useful and at the present moment it is the most extensive account of the kind available in English. R. F. Mehl (5b)-B-



The Structure of Thin Films of Certain Metallic Oxides. W. L. BRAGG & J. A. DARLINGSHIRE. *Transactions Faraday Society*, Vol. 28, June 1932, pages 522-529. A narrow electron beam was allowed to fall normally on thin oxide films and the diffraction pattern was recorded on a photographic plate. The structure of a thin transparent film of oxide stretched over holes in a thin film of metallic Zn was not the hexagonal ZnO structure but one best explained as a face centered cube of side 4.62 A.U. with certain discrepancies such as misplacement of 111 and 200 reflections and the unaccountable presence of 110 and 321 reflections. Another method of preparing ZnO gave the hexagonal pattern. PbO_2 gave the expected tetragonal rutile structure. SnO_2 gave the rutile type structure with the Sn atoms on a body centered tetragonal lattice with $a = 4.72$ A.U. and $c = 3.17$ A.U. PRK (5b)

Electron Diffraction and Inner Potential of Metals. (Elektronenbeugung und inneres Potential der Metalle.) A. BRÜHL. *Die Naturwissenschaften*, Vol. 20, July 29, 1932, pages 577-578; discussion: R. FRISCH. Sept. 9, 1932, page 689. New method of magnetic diffraction analysis for studying the space lattice potentials of metals is stressed and 7 formulae are derived. Determination of inner potential of Ag gave 0 ± 2 volts, while Frisch claims 14 volts in discussion. EF (5b)

The Structure of Rolled Zinc and Magnesium. (Die Walztextur von Zink und Magnesium.) V. CAGLIOTTI & G. SACHS. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XXI, 1933, pages 42-46. See *Metals & Alloys*, Vol. 3, Sept. 1932, page MA 268. (5b)

X-Rays as a Research Tool in Chemistry and Industry. GEORGE L. CLARK. *Industrial & Engineering Chemistry*, Vol. 24, Feb. 1932, pages 182-190. Properties of X-rays which may be applied for research purposes are briefly reviewed. Among many applications are mentioned study of structures of alloys of Fe, for which the periodic classification by Wever is included, detection and estimation of internal strain in crystals, and results of rolling and heat-treating metals to remove undesirable directional properties that are revealed by X-ray fibre patterns. 19 references. The "Hoover Dam" 300,000 volt shock-proof G-E x-ray unit ready for shipment

G-E X-Ray Equipment to radiograph penstocks at Hoover Dam

WHEN Babcock & Wilcox were awarded the penstock contract for the colossal Hoover Dam project, they found themselves faced with the mammoth task of checking every inch of all fusion welds by radiographic inspection. *These fusion welds totaled more than 75 miles in length!*

Based on their experience with G-E x-ray equipment in their Barberton plant, Babcock & Wilcox turned to the General Electric X-Ray Corporation for apparatus which would fulfill these stipulations. As a result, they have been equipped with the 300,000 volt oil-immersed x-ray unit shown here.

This equipment, the most powerful shock-proof industrial x-ray apparatus in use at the present time, has its complete high tension system—transformers, condensers, Kenotrons and x-ray tube—completely immersed in oil and sealed within a compact tank or "head." This head will be so mounted that the x-rays can be quickly directed at any angle required. There is no possibility of accidental high tension shock, as the only external wiring is at low tension, connecting the head, control stand, and power source.

Write today for our profusely illustrated descriptive brochure "Industrial Application of the X-Ray." Address Industrial Department.

Chemical Analysis by X-Rays and Its Applications. GEORG VON HEVESY. McGraw-Hill Book Company, New York, 1932. Cloth, 6¼x9¼ inches, 333 pages. Price $3.00. This book covers in clear and authoritative fashion the theory and technique of chemical analysis by X-rays (Part I) and gives examples of the application of this method to the discovery of hafnium (Part II) and to the problems of the chemical composition of the earth, meteorites, and the sun (Part III).

Profesor Hevesy has an entertaining way of writing the parts of the book dealing with the history of the subject. With personal reminiscences he enlivens the story of Roentgen's discovery of X-rays, Mosely's researches, the development of the Bohr theory of atomic structure, and the discovery and isolation of hafnium.

The book is far more than a history, however. The half of the book (Part I) devoted to the instruments, methods, and precautions to be used in qualitative and quantitative X-ray analysis is so complete, so carefully and elegantly done, that it will be invaluable to workers in the field. The illustrations are excellent; a great number of graphs have been advantageously used for clear presentation of the properties of X-rays, and numerous microphotometer traces of spectral lines to illustrate the author's findings have been included. Extensive tables make the work of practical value as a handbook in the laboratory: X-ray emission lines and absorption limits, percent of photographically effective absorption in X-ray plates, intensity ratios of emission lines, atomic ratios supplying diffraction lines of equal density, reflection angles versus wave-length for calcite and gypsum crystals, a table of elements whose emission lines and absorption edges lie at such wave-lengths as to cause errors in the quantitative analysis of each of the elements from atomic numbers 12 to 92.

In the second half of the book is a most complete listing of the properties of hafnium and its compounds, including a tabulation of the arc and spark lines in the optical spectra of hafnium. There are interesting essays on the age of the earth, the nature and composition of meteorites and their significance with respect to the age of the earth's material and with respect to the composition of the earth, the sun, and the solar system. The presentation of researches in this field is justified by the fact that analysis by X-rays here finds its most effective application. Space was not available for a comprehensive treatment of these studies, yet the book serves as an effective introduction to them and is armed with extensive references to original sources.

In the metallurgical field examples are given of the quantitative analysis of Cu-Zn, Sn-Cd, Pb-Bi, Cu-Zn-Sn, Pb-Zn, and Zn-Sn alloys. The direct method of analysis yields satisfactory accuracy in these cases if the elements are not too widely different in atomic number, but indirect (comparison) methods must be used when atomic numbers differ greatly, such as in Eddy and Laby's determination of the Pb contents of Zn in the range 0.008-0.064% Pb. The sensitivity of X-ray analysis varies with the atomic number of the elements to be determined, reaching 1 part in 10^4 or 10^5 with heavy elements.

The metallurgist should be referred to this book for an authoritative and unbiased comparison of X-ray and optical spectroscopy, or of analysis by absorption discontinuities and by emission lines, or of the relative advantages of primary and secondary radiation in spectroscopy. No previous knowledge of X-ray spectroscopy is required for an understanding of the work; in fact it is probable that a person could make successful X-ray analyses with no other knowledge of the subject than is here given.
C. S. Barrett (5b)-B-

Methods of Crystal Structure Determination with X-Rays. The Laue Method. (Methoden der Kristallstrukturbestimmung mit Röntgenstrahlen. Die Lauemethode.) E. SCHIEBOLD. Akademische Verlagsgesellschaft, Leipzig, 1932. Paper, 6½ x 9½ inches, 173 pages. Price 13 RM. This monograph on the Laue method is the first of a series of 3 on the use of X-rays in crystal structure determination. The second volume, now in press, is devoted to the rotating crystal method and X-ray goniometry; the third, in preparation, covers the powder method. The author confines his attention to those methods which have proved most generally useful and strives for a thorough treatment of these rather than a briefer discussion of all the methods that have been devised. Space is saved by assuming the reader's familiarity with the elements of crystallography, mathematics and X-rays. The result is a text excellent for use in teaching advanced courses in crystallography, and for use as a handbook in the research laboratory.

The first volume contains the trigonometric formulas and graphical methods for assigning indices to Laue spots, well illustrated with examples. The major part of the book covers the Laue methods for the determinations of symmetry, axial ratio, lattice dimensions, translation group, space group and parameters of crystals. Tables giving the missing reflections for space group analysis are not given but their derivation and use are explained. A third of the book is devoted to the intensity of reflection, including Laue's theory, a brief discussion of the dynamic theory, the several intensity factors, the characteristics of the photographic emulsion, and the shape of the Laue spots.

Metallurgical laboratories will find the treatment of reflection from distorted lattices rather brief. Laue methods of orientation determination are barely mentioned, and rotation nets for stereographic and gnomonic projections are not reproduced, but metallurgists will welcome the volume as a most authoritative and detailed treatise on the Laue method of crystal structure analysis. Because of the fact that none of the well-known X-ray books attempt to give exhaustive treatments of technique, this series of monographs is especially acceptable. C. S. Barrett (5b)-B-

Defect Recognizability in X-raying. (Fehlererkennbarkeit bei Röntgenuntersuchungen.) K. HEYER. *Schriften der Hessischen Hochschulen*, 1932, No. 4, pages 79-81. Paper presented at 25th Anniversary of Staatliche Materialprüfungsanstalt Technische Hochschule Darmstadt, Oct. 29, 1932. Use of X-rays for radiography depends on (1) cost, (2) degree of defect recognizability and measuring accuracy. A brief account is given of tests on the dependence of defect recognizability on tube voltage, focal distance, field range (area to be radiographed) and wall thickness of part to be radiographed. GN (5b)

X-Ray Technique for Examination of Four-Inch Steel. R. E. HILLER. *General Electric Review*, Vol. 35, July 1932, pages 376-380. Advantages of radiography as a method of testing welds are discussed. With new fine-focus X-ray tube and high-voltage outfit capable of operating continuously at 300,000 volts, production examination of more than 350' of welded seams in mercury boiler drums constructed of plate 4⅛" thick has been made. The new tube is 4' long with a bulb 8" in diam. and is constructed of pyrex glass ¼" thick. The target is a W disc held in a water cooled Cu block. Auxiliary equipment and plant arrangement is discussed. Exposure and operating details are included as well as typical radiographs of welds. CBJ (5b)

On the Nature of the Tetragonal and Cubic Martensites. KOTARO HONDA & ZENJI NISHIYAMA. *Science Reports Tohoku Imperial University*, First Series Vol. 21, No. 3, Oct. 1932, pages 299-331. First product of quenching C steel is always tetragonal (α) martensite; it is an interstitial solid solution of C in Fe. It is unstable and easily changes into cubic (β) martensite by shocks, such as grinding. The a-axis of α martensite slightly decreases and its c-axis increases linearly considerably with C content. Lattice constant of austenite increases linearly with C content. Quenching temperature does not affect lattice constants of the specimen. By tempering a quenched steel at 100°-150° C., α martensite changes into β martensite. By quenching a C steel in a refined rape seed oil at 150° C., β martensite is obtained. Lattice constant of β martensite increases with C content. β martensite continuously decomposes as temperature is raised slowly but not at a definite temperature. C atoms in martensites are interstitial and their position in the lattice of α martensite is (½, ½, 0), and that in the lattice of β martensite is (½, ¼, 0). Öhman's C_2-replacement theory for structure of martensite was shown to be untenable. AHE (5b)

The Structure of the Surface of Ground Metal Crystals. (Über die Struktur der Oberfläche geschliffner Metallkristalle.) W. BOAS & E. SCHMID. *Die Naturwissenschaften*, Vol. 20, May 27, 1932, pages 416-419. Research work on the structural changes at the surface of metals due to grinding and polishing is historically reviewed. The investigators applied very short-wave X-rays to secure Laue reflection diagrams of Al, Cu, Zn, Cd and Sb. Grinding and polishing of metal crystals results in the formation of 2 layers in the metal (a) a fine-crystalline layer at the surface and (b) a 10 times thicker deformed transitional layer. Crystal orientation exerts a marked influence upon the thickness of the occurring layers. Differences for translation possibilities are responsible for less pronounced penetration depth of disturbances in case of cubic metals. EF (5b)

The Crystal Structure of Black Nickel. H. KERSTEN & JOSEPH MAAS. *Physics*, Vol. 3, Sept. 1932, pages 137-138. Shown by means of X-ray diffraction analysis that electrodeposited black Ni has an amorphous structure which changes to a crystalline structure when deposit is heated. WAT (5b)

X-ray Determination of Alloy Equilibrium Diagrams. ARNE F. WESTGREN. *Transactions American Institute of Mining & Metallurgical Engineers, Institute of Metals Division*, Vol. 93, 1931, pages 13-38. Lecture given Feb. 1931. Deals mainly with the identification of phases in alloy systems, their homogeneity ranges, and structural analogies. The most important work of the author and his associates is reviewed. See also "X-Ray Investigations of the Constitution of Alloys," *Metals & Alloys*, Vol. 4, Apr. 1933, page MA 108. JLG (5b)

An X-ray Diffraction Chamber for Investigations at Elevated Temperatures. (Eine Röntgen-Interferenzkammer für Reihenuntersuchungen bei hohen Temperaturen.) R. BERTHOLD & H. BÖHM. *Metallwirtschaft*, Vol. 11, Oct. 14, 1932, pages 567-569. A newly developed apparatus is described in detail which overcomes the shortcomings of previous types. The sample is heated in a small cylindrical carbon resistance furnace of only .3 mm wall thickness. The end of a thermo-couple is also placed inside the furnace. There are small holes in the wall of the furnace for the entrance and exit of the primary X-ray and the thin wall does not weaken the diffraction rays appreciably. Temperatures up to 1500°C. are obtainable. The apparatus is manufactured by Siemens & Halske A.G. CEM (5b)

Performance and Efficiency in X-raying Welds. (Leistung und Wirtschaftlichkeit der Röntgenprüfung von Schweissungen.) R. BERTHOLD. *Elektroschweissung*, Vol. 3, Nov. 1932, pages 201-205. Paper discusses: (1) technique of X-ray weld seam testing on I-joints, V-, X-, and T-seams, lap welded joints and round seams of small, medium and large dimensions, (2) "exposure factor" and limits of translucence. (The exposure factor is defined as the product of exposure time in sec. by tube amperage.) (3) recognizability of defects, (4) efficiency which depends on technical importance of parts free from defects and on costs of examination, (5) costs of testing weld seams by radiography. GN (5b)

The Persistence and Development of Crystal Nuclei above the Melting Temperature. WILLIAM T. RICHARDS. *Journal American Chemical Society*, Vol. 54, Feb. 1932, pages 479-495. Crystal form may persist above melting point if an adsorbent is present for which heat of binding of crystalline adsorbate is greater than that of liquid adsorbate. This hypothesis is seen to be successful in accounting for behavior of undercooled liquids observed by other investigators, and to supply a plausible explanation for further experiments. Possible applications of this viewpoint to X-ray diffraction, purification of materials, treatment of glasses and alloys, and thermodynamic theory of adsorption are briefly indicated. MEH (5b)

Fine Structure of α-Rays from Thorium C (Sur la structure fine des rayons α du Th C). S. ROSENBLUM & M. VALADARES. *Comptes Rendus*, Vol. 194, Mar. 14, 1932, pages 967-970. Authors repeat previous work with a more powerful electro-magnet and improved experimental conditions. Previous results are confirmed and 2 new lines are observed, one being, however, doubtful. OWE (5b)

Structure and Property Changes during Transition Process. (Allgemeine Gesetzmässigkeiten der Gefüge- und Eigenschaftsänderungen bei Umwandlungsvorgängen.) G. SACHS. *Zeitschrift für Metallkunde*, Vol. 24, Oct. 1932, pages 241-248. Includes discussion. Paper before Deutsche Gesellschaft für Metallkunde, June 26, 1932. A review. 20 references. RFM (5b)

A New Method for Testing the Faultlessness of Goldsmith Work. (Eine neue Methode zur Prüfung der Fehlerfreiheit von Goldschmiedearbeiten.) E. SCHIEBOLD & F. LUFT. *Deutsche Goldschmiedezeitung*, Vol. 35, Nov. 5, 1932, pages 448-449. Discusses difficulties encountered in examining faultlessness of gold ware by X-rays which are particularly due to the limited penetrating power of X-rays for metals of high specific gravity. New γ-rays are suitable for radiographic examination of such metals. 4 references. GN (5b)

Internal Stresses in Hardened and Tempered Steel Wire. (Tensioni interne in fili di acciaio incrudito e rinvenuto.) D. FAGGIANI. *La Metallurgia Italiana*, Vol. 24, Aug. 1932, pages 637-642. Steel wire, containing 0.85% C was hardened and then tempered at temperatures varying from 250-650° C., and the internal stresses measured by means of X-rays using the Debye chamber. Above 650° C., the stresses are completely neutralized, and were, therefore used as a basis for comparison. Heating for 10 hours at 250° C. neutralizes only a small percentage of the stresses, while only 30 minutes at 350° C. gives 19% neutralization, and 30 minutes at 400° C. gives over 63% neutralization. The curve, temperature-stress, shows a point of inflection at 400°-500° C., and shows that tempering must be carried out at temperatures over 650°C. in order to eliminate all internal stresses. AWC (5b)

Apparatus for Testing of Materials by X-Rays. (Apparate für die Materialuntersuchung mit Roentgenstrahlen.) O. FISCHER. *Autogene Metallbearbeitung*, Vol. 25, Nov. 1, 1932, pages 321-325. Development of equipment for X-ray testing is reviewed and principal points, i. e. danger of high-tension and danger of physiological effects of X-rays, explained. Various means to obtain a safe, portable unit for testing in shop and other places are illustrated. A chart is given from which times of exposure for different voltages up to 180,000 v. and for different thicknesses of Fe can be taken. Ha (5b)

Transitions in the System Gold-Copper. (Die Umwandlungen im System Gold-Kupfer.) L. GRAF. *Zeitschrift für Metallkunde*, Vol. 24, Oct. 1932, pages 248-254. Includes discussion. Paper before Deutsche Gesellschaft für Metallkunde, June 26, 1932. A review. RFM (5b)

Fine Structure in X-Ray Absorption Spectra. J. D. HANAWALT. *Journal of Franklin Institute*, Vol. 214, Nov. 1932, pages 569-584. Writer has considered Kronig idea that following ionization process ejected electron must travel in periodic potential field of crystal lattice in quantum mechanically prescribed way. This theory permits one to understand principal experimental observations. These are as follows: (1) absence of fine structure for isolated atoms, and dependence of fine structure upon atomic aggregate; (2) temperature effect of vanishing of structure; (3) temperature effect of wave-length shift of structure; (4) $\frac{1}{a^2}$ form of energy; (5) identity of fine structures of different elements in same crystal; (6) close relation of character of structure to crystal structure of substance. 20 references. DTR (5b)

The Theory of Magnetostriction. (Zur Theorie der Magnetostriktion). TAKESI HAVASI. *Science Reports Tohoku Imperial University*, Vol. 21, July 1932, pages 268-287. Theoretical investigation of lattice energy of magnetized crystal shows that ferromagnetic substances contract in direction of field and expands in perpendicular direction and that change depends on shape of crystal. Ha (5b)

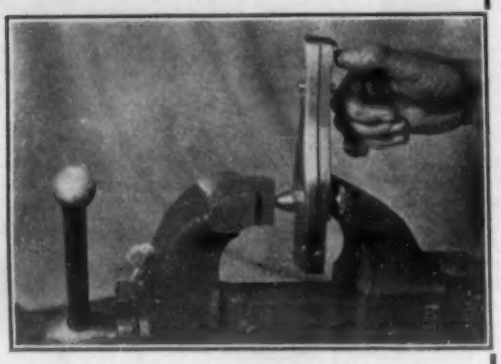
PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Fatigue of Metals (6f)

The Testing of Wire and Wire Rope. A. V. DeForest & L. W. Hopkins. *Proceedings American Society for Testing Materials*, Vol. 32, Pt. 2, 1932, pages 398-412. Tests of individual wire are described in which the wire is subjected to reversed flexure with a small steady tension. In the machine used an unmachined piece of wire is held in a motor-driven drill chuck and hung over a sheave wheel on an arc of 90°. The wire is rotated about its axis, and the sheave wheel is slowly rotated away from the drill chuck. A weight is attached to the free end of the wire through another chuck. The amount of stress set up is determined from the diameter of the wire and the diameter of the sheave wheel used. The wire is lubricated, as it rotates in the sheave groove, with oil saturated with colloidal graphite. For preliminary tests reported the following average values were found for endurance ratio (Endurance limit: Tensile Strength): Iron wire 0.60; toughened steel wire 0.47; cast steel wire 0.39; mild plow steel wire 0.34; plow steel wire 0.35; improved plow steel wire 0.29. Some tests of wire ropes were also reported, and testing machines for such fatigue tests described. Comparative tests were made of rope "preformed" in which component wires before being incorporated into rope were formed into the shape of the helix they are to assume in the rope, and of ropes made of wires not so preformed. Preformed ropes showed a decidedly greater fatigue strength than did ordinary ropes in all comparative tests tried. "Preformed" ropes did not develop quite the fatigue strength shown by individual wires. Several other tests of wire and wire rope are described, and a brief discussion of effect of wire rope structure on its strength is given. HFM (6f)

Alternating Torsion Tests Round 360° for Wire used in Aerial Ropeways and Cable Railways (Essais de torsion alternée de 360° sur fils de câbles métalliques pour téléférages et funiculaires). P. Forcella. *International Association for Testing Materials, Zurich Meeting, 1931*, Vol. 1, 1932, pages 266-277. The usual tests for cables, wires, tension, bending and torsion did not differentiate between wires taken from cables that had failed in service and those that had given good service, but reversed torsion tests involving a comparatively few cycles of twist did differentiate. Low figures for reversed torsion and the splitting of the wire in the test were ascribed to inclusions. It is suggested that the bend test of the present specification be replaced by a short-time repeated torsion test. A test length of 20 cm., a simultaneous tensile load of 4 kg./mm.^{2} for 0.5 mm. and 10 kg./mm.^{2} for 1 to 3 mm. wire and reversed torsion through 360° are suggested. Under these conditions wires of 0.5, 1, 2 and 3 mm. diameter should give 300, 200, 100 and 50 reversals without failure, on wire of 230,000-255,000 lbs./in.^{2} tensile. In this connection the abstractor notes the effort made some years ago by the A. S. T. M. to introduce the requirement at a certain "life" under reversed flexure for staybolts. After a few years' trial the requirement was abandoned as the results in commercial testing proved very erratic. HWG (6f)

Fatigue-impact and Alternating Bending Tests on Rails of the Italian Railways (L'essai aux chocs répétés a flexion alternée sur les rails des chemins de fer italiens). P. Forcella. *International Association for Testing Materials, Zurich Meeting, 1931*, Vol. 1, 1932, pages 247-267. The tensile test, the single blow impact test (Mesnager bar) and the repeated impact test (Amsler machine, grooved bar turned 180° between blows) have been applied to specimens cut from many old rails and from new ones being put in service. Rails that failed in a brittle fashion in service gave both low impact, and low repeated impact figures, the specimens in the latter test breaking clear through and not progressively from the 2 sides as shown by photographs of the fractures. The author so thoroughly believes in the repeated impact test that he terms it the "index of durability." Poor rails, according to Forcella's standard, show about 1 kgm./cm.^{2} impact, and 500-2500 blows in repeated impact, while good ones show 3 to 4 kgm./cm.^{2} and 5000-10,000 blows, and their structure shows a continuous ferrite network. The best composition is about 0.45% C, 1.2-1.4% Mn, 0.05-0.15% Si, 0.15-0.45% Cu. The Mn may be raised to 2% and the C dropped to 0.35% and the rail reheated and normalized, then testing 120,000 lbs./in.^{2} tensile, 6 kgm./cm.^{2} and 12,000 blows. This composition may be compared with American practice which allows a C content in rail steel from 0.60-0.89%. The wear resistance of these low C rails is not discussed, the author apparently being more interested in avoiding the possibility of a shattering fracture than in avoiding wear or end batter. HWG (6f)



Effect of Zinc Coatings on the Endurance Properties of Steel. W. H. Swanger & R. D. France. *American Society for Testing Materials, Preprint* No. 40, June 1932, 19 pages; *Bureau of Standards Journal of Research*, Vol. 9, July 1932, pages 9-24. The paper describes tests made at the Bureau of Standards on open hearth Fe, as rolled and on 0.45 C steel and 0.72 C steel annealed, quenched, and tempered. Rotating-beam and axial reversed stress tests were made on uncoated metal and on galvanized (hot dip) metal. Rotating-beam tests were also made on metal pickled, and on metal electroplated. S-N diagrams and micrographs of steel and of coatings are given. A decrease from the endurance limit of the uncoated polished specimens was shown for the pickled steel, the decrease ranging from zero to 40%, and being larger for the quenched and tempered specimens than for the annealed. For the hot dip galvanized specimens the corresponding decrease of endurance limit ranged from 4.0% to 42.5%, and in this case the quenched and tempered steels were more adversely affected than the annealed. The electroplated specimens showed endurance limits slightly higher than the endurance limits for uncoated and polished metal. The authors state that the difference in the strengths shown by the 2 types of coating is believed to be due to the nature of the bond between Zn and steel and the differences in structure and hardness of the 2 coatings. WAT + VVK + HFM (6f)

The Development of Fatigue Testing in Germany. (Über die Entwicklung der Dauerprüfung in Deutschland). E. H. Schulz & H. Buchholtz. *International Association for Testing Materials, Zurich Meeting, 1931*, Vol. 1, 1932, pages 278-303. Various types of fatigue testing machines used in Germany are discussed and sketches shown. "Accelerated" tests are not reliable for non-ferrous metals, and on steel get no closer to the truth than can be gotten by calculation from static properties. The effect of notches is discussed in regard to reversed stress alone, and to static stress plus reversed stress, the reversed stress being either between the same, or different, limits of tension and compression. Effect of holes and of a soft skin are also described. Corrosion-fatigue is discussed and beneficial effect of Cu in German Cu Cr structural steel is especially commented upon. There are close relationships between the damping properties, the propensity to damage by notches and the ability to be strengthened by understressing, but so far it has not been possible to express the relationships quantitatively. 35 references. HWG (6f)

Fatigue Failure under Repeated Compression. H. R. Thomas & J. G. Lowther. *Proceedings American Society for Testing Materials*, Vol. 32, Pt. 2, 1932, pages 421-429; *Iron & Steel Industry & British Foundryman*, Vol. 5, Sept. 1932, pages 429-431. Tests of fatigue specimens are reported in which failure apparently occurred under cycles of compressive stress with no reversal to tension. The tests were tests in "one way" bending on T-shaped specimens with the stem of the T in compression. Specimens of ordinary structural steel started fatigue cracks in the compression-stressed stem, but specimens of rail steel and of duralumin did not. An investigation of the plastic action involved in the tests indicated that after a few cycles of stress in the specimens of structural steel there was actually a slight reversal of stress to tension in the stem. Probably this residual tensile stress helped in the formation of a fatigue crack. In the oral presentation of the paper fatigue failures were reported in structural specimens subjected to cycles of axial compression with no reversal to tension. Fatigue cracks have also been observed in rail specimens under repeated loading at regions where the stress seems to be repeated compression with no reversal to tension. CHL+HFM (6f)

THE DWARF BRINELL PRESS

FOR SOFT METALS

Tests the hardness with a 250-kg. load and 5-mm. ball.

THE THUMB NAIL is used to test the pressure!

Read how this is possible in our Bulletin H-4 —yours on request.

Brinell numbers are read directly by the magnifying glass with the cam dial. Other unique features.

THE R. Y. FERNER COMPANY

1511 K Street N.W. Washington, D. C.

NEARLY half the 1600 rooms at the William Penn Hotel have now been reduced to $3.00 and $3.50. A NEW DEAL for everybody! The same excellent service, the same luxurious appointments at Pittsburgh's finest hotel. All rooms with bath . . . Management Eppley Hotels Co.

HOTEL WILLIAM PENN PITTSBURGH

Also the FORT PITT HOTEL—good rooms from $1.50; with bath $2.00

ELECTRO-CHEMISTRY (7)

The Problem of Electrolytic Dissociation. II. Reply to the Statements of Hammerschmid and Lange. (Das Problem der elektrolytischen Dissoziation. II. Zugleich eine Entgegnung auf die Erwiderung der Herren Hammerschmid und Lange.) K. Fredenhagen. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 159, Mar. 1932, pages 81-98; 110-114. This reply to a previous discussion of Hammerschmid & Lange (see *Metals & Alloys*, Vol. 3, May 1932, page MA 128) states that the electrolytic solution or distribution values are closely related to the Nernst electrolytic solution pressure. The only uncertainty adherent to the solution pressure and p-values is, that we only know their relative, but not their absolute value. The author denies that an appreciable contact potential difference metal/metal occurs while measuring e.m.f's. Fredenhagen discusses the relationship between gas atoms and solution ions and declines to interpret the phenomenon of electrolytic dissociation on the basis of electrostatic forces which are replaced by specific chemical forces. EF (7)

Notes to a Discussion with Fredenhagen. Criticism on the Reasons for Neglecting the Galvanic Potential Metal/Metal in Galvanic Cells. (Schlussbemerkungen zur Diskussion mit Herrn K. Fredenhagen. Zugleich Kritik einiger vermeintlicher Gründe für die Vernachlässigung des Galvanipotentials Metall/Metall in der galvanischen Kette.) H. Hammerschmidt & E. Lange. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 159, Mar. 1932, pages 100-109. The writers present evidence that the galvanic potential metal/metal in a galvanic cell cannot be disregarded and discuss some further problems on ion transitions dealt with in the controversy with Fredenhagen. (See abstract above.) EF (7)

The Influence of the Electrode Surface on the Conductivity in Dielectric Liquids. (Über den Einfluss der Oberflächenbeschaffenheit der Elektroden auf die Stromleitung in dielektrischen Flüssigkeiten.) H. Edler & C. A. Knorr. *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 158, Feb. 1932, pages 433-440. It is highly probable that the nature of the electrode surface plays an important role during the formation of the charge carriers. Using Pt-electrodes and benzol as a dielectric medium, the experiments proved that the course of the characteristic amp/volt curve actually depends on the hydrogen content of the electrode. EF (7)

The Hydrogen Over-voltage on Alloys. (Die Wasserstoffüberspannung bei Legierungen.) H. Flood. *Zeitschrift fur physikalische Chemie*, Abt. A, Vol. 159, Mar. 1932, pages 131-134. Observations on the hydrogen over-voltage on alloys are theoretically interpreted on the basis of Stranski's assumption on crystal growth. EF (7)

A New Electro-Chemical Method in Radio-Chemistry. (Ein neuartiges elektrochemisches Verfahren der Radiochemie.) O. Erbacher. *Die Naturwissenschaften*, Vol. 20, May 27, 1932, pages 390-393. See *Metals & Alloys*, Vol. 3, June 1932, page MA 170. EF (7)

Electro-chemical Industry. S. Wernick. *Electrical Review*, Vol. 110, June 17, 1932, page 904. Brief review of electrolytic production and refining of metals, including recovery of precious metals, electroplating and electroforming. MS (7)

The Recovery of Dissolved Gold and Silver by Means of Aluminum. (Die Wiedergewinnung gelösten Goldes und Silbers mittels Aluminium.) R. J. Snelling. *Deutsche Goldschmiedezeitung*, Vol. 45, Aug. 13, 1932, pages 332-333. Up to the present time precipitation and recovery respectively of Au and Ag from KCN solutions was nearly exclusively done by Zn, Al was found to be much better. A considerable saving in the consumption of KCN can be effected. GN (7)

On the Polarization Potential in the Cathodic Deposition of Zinc from the Aqueous Solution of Zinc Sulphate. T. Isihara, K. Mihara & K. Umetu. *Kinzoku no Kenkyu*, Vol. 9, No. 6, 1932, pages 244-278. The cathodic polarization and the anodic overvoltage in the electrolysis of Zn sulphate solutions of different strength and acidity were measured by a direct method with a normal calomel electrode and a potentiometer. The anode was a platinized Pt plate and the cathode was of Zn electroplated on a coppered Pt plate. Current density—single potential curves were determined for both electrodes up to 12 amp./dm.^{2} at 35°C. The concentration of $ZnSO_4$ was chosen between 0.5 and 3 N and that of H_2SO_4 between 0 and 3 N with intervals of 0.5 N. The single potential of the Zn cathode at no current decreased in its absolute value with increasing $ZnSO_4$ concentration and the formula, $E = E_o + 2.3026 \frac{RT}{nF} \log C$, held in the case of neutral solutions. The decomposition potentials determined from the current-potential curves were found to increase with increasing concentration of $ZnSO_4$, which was explained to be due to the increase of overvoltage of oxygen with increasing $ZnSO_4$ concentration. But both the decomposition and the over-voltages decreased when the $ZnSO_4$ concentration exceeded 2.5 N. These general features were found also in the case of acidified solutions, the decomposition potential being maximum at 1.5 to 2 N $ZnSO_4$. The maximum was less marked for higher acidities than 2 N. When the acidity was varied at constant $ZnSO_4$ concentrations the decomposition potential was maximum at about 1 N H_2SO_4. The cathodic polarization was lowered by increase in $ZnSO_4$ concentration, but, in the case of neutral and 0.5 N H_2SO_4 solutions, it increased when the $ZnSO_4$ concentration exceeded 2 N. Although the cathodic polarization has a general tendency to decrease with increasing $ZnSO_4$ concentration for acidities higher than 1 N, discontinuities are stated to exist on the effect of $ZnSO_4$ concentration at about 2 N. The cathodic polarization being much smaller in magnitude than the anodic overvoltage, the total polarization is determined mainly by the latter. The overvoltage at the anode generally increased with increasing $ZnSO_4$ concentration. From the point of view of polarization and conductivity, the solutions acidified with less than 1 N acid are more desirable than the neutral one in the electrodeposition of Zn. YO (7)

Electroplating (7a)

Gold Solutions for Production Work. J. L. Merigold. *Brass World*, Vol. 28, May 1932, pages 95-97. See *Metals & Alloys*, Vol. 3, Nov. 1932, page MA 323. WHB (7a)

A Chromium Plating Bath with Fluoride Ion. A. Perlenfein. *Rensselaer Polytechnic Institute Bulletin*, No. 39, Feb. 1933, 36 pages. Instead of adding sulphate ion to chromic acid bath as originated by Sargent and followed by Fink, Perlenfein (following up similar work done since 1922 under the direction of M. A. Hunter) uses fluoride ion instead. There is a marked difference in the 2 baths, in that sulphate needs to be kept in constant ratio to chromic acid, making constant control of composition desirable, while fluoride needs only to be kept about constant, while chromic acid content may vary 100%. A bath of 10 g./l. sodium fluoride and 250 g./l. chromic acid is recommended, but chromic acid may drop to 125 g./l. Not much more than 10 g./l. sodium fluoride can be used. Chromic acid sodium fluoride bath has a wider bright-plating range than bath with sulphate, and deposits are brighter, with a more silvery luster. At 45-50° C. the current density may vary from 20 to 60 amp./cm.^{2} or higher. On account of higher current density and efficiency it will plate faster than sulphate bath. Deposit is stated to be more impervious than that from the sulphate bath when plated direct on Fe. Various other advantages are mentioned. Hambeuchen, in U. S. Patent 1,544,451, of June 30, 1925, which antedates the sulphate-control patent, covered chromic acid sodium fluoride electrolytes, but Schneidewind tried to use such baths without results. Perlenfein's preferred composition, however, is within Hambeuchen's range. Literature of chromium plating is reviewed. H. W. Gillett (7a)-B-

Electrometallurgy (7b)

1 **The Production of Heavy Metals by the Electrolysis of Fused Salts. III. Inactive Anodes for High Temperatures. (Ueber die Gewinnung der Schwermetalle durch Schmelzelektrolyse. III. Indifferente Anode fur hohe Temperaturen.)** F. Sauerwald. *Zeitschrift für Elektrochemie*, Vol. 38, Feb. 1932, page 76. A water-cooled Cu anode is described. In order to avoid corrosion in the molten electrolyte ($FeO \cdot SiO_2$) at 1250° C. the anode is placed 5-10 mm. above the surface of the liquid, and the current is passed as an arc across the gap. Even under these conditions, however, the service of the anode is only 2-3 hrs. Ha (7b)

2 **Electrolytic Gold Refining.** *Electrical Review*, Vol. 110, June 3, 1932, page 803. Modern method, with HCl electrolyte, consists of using direct current, on which is superposed an alternating-current. Advantages over older method are use of higher current-densities, elimination of Cl evolution, and smooth solution of Au. Anodes made of melted down sovereigns and similar Au coins can be refined at a current density of 116 amp./ft.^{2}, whereas in the absence of a.c., the maximum permissible is 70 amp./ft.^{2}. Ratio of a.c. to d.c. is 1.1, but this may be increased considerably. Bullion containing 20% Ag may be refined at a current density of 112 amp./ft.^{2}, ratio of a.c. being raised to 1.7. Much higher current density can be used for comparatively pure bullion. Scarcely 1% Au enters anode slimes. Superposed current eliminates passivity of Au anode due to layer of AgCl. Elimination of this passivity is most effective when a.c. of low frequency is used. Heating of the electrolyte is unnecessary. MS (7b)

Electrolytic Reduction of Antimony from Ores. N. A. Isgarischev & S. A. Pletnev. *Tzvetnuie Metallui*, No. 5, May 1931, pages 582-586. See *Metals & Alloys*, Vol. 3, Oct. 1932, page MA 299. BND (7b)

3 **Electrochemical Industries in Japan. (Les industries électrochimiques au Japon.)** *Journal du Four Electrique*, Vol. 41, Aug. 1932, pages 289-291. Abstract of the paper by Naoto Kameyama presented at the 5th International Congress of Electricity. 6 electrolytic refineries produce practically all Cu made in Japan. Ag and Au are separated either by Moebius or Malbach processes, the former has its scrapers eliminated, the suspension bars for cathodes shaken mechanically to break off the Ag treeing and the cells arranged in cascade. 3 fluosilicate Pb refineries treat 3600 tons per year, practically all Japanese production of the metal. 2 electrolytic Zn refineries make about 4000 tons of the metal a year. In 1929 a sulphate iron electrolytic plant with production of 70 tons per year was started. About 1000 tons of Na are made by electrolysis of hydroxide. A quite ingenious and original electrolytic plant for Mg is being built. No Al is made on account of the lack of bauxite. 3 methods for production of Al_2O_3 are being tried. Suzuki-Tanaka fuses clay with carbon in electric furnaces, removes ferro silicon produced and volatilizes their traces from alumina by heating it with chlorine at 200-400° C. Yamasaki dissolves clay in H_2SO_4, adds $(NH_4)_2SO_4$ crystallizing ammonium alum from the solution containing Fe. Alum is treated with ammonia precipitating $Al(OH)_3$ which is then treated in the usual way. In Tanaka's method clay is treated in an autoclave with a 10% solution of SO_2 in water kept under pressure and at 73° C. Al is separated as sulphite. On heating this solution in open vessels the sulphite decomposes into SO_2 and a precipitate of $5Al_2O_3 3SO_3$ which is entirely free from Fe. It is transformed into alumina by calcination with recovery of SO_2. JDG (7b)

5 **Practical Experiences on the Importance of the Hydrogen Absorption in the Refining of the Surfaces of Metals. (Praktische Erfahrungen über die Bedeutung der Wasserstoffaufnahme bei der Oberflächenveredelung von Metallen.)** Richard Justh. *Oberflächentechnik*, Vol. 9, July 19, 1932, pages 145-148; *Korrosion und Metallschutz*, Vol. 8, Mar. 1932, page 84; May 1932, pages 120-125. The importance of the absorption of gases, especially of H, in the electrolytic refining is pointed out and the part of H in the deposition of metals discussed. All Pt and Fe metals (Co and Ni) absorb H in their electrolytic deposition from aqueous solutions due to the fact that the H atoms discharged during electrolysis are converted into molecular H only after passing through H alloys first. These H-metal alloys are of great importance for the adhesion of the deposits. A practical result of this knowledge was that a corrosion-protective deposit of Cr was not made directly on a metal, as Cr absorbs great amounts of H, but on intermediary layers which actually prevent corrosion and where Cr plays only the part of decoration and hardening and has generally a thickness of 0.05-0.5 mm. The hardness of a metal deposit depends to a greater extent on the composition and operation of the baths than on the H-absorption with exception of Cr deposits. The following table shows some figures:

6

Metal	Brinell Hardness	Metal	Brinell Hardness	Metal	Brinell Hardness
Lead	3-5	Silver	61-130	Nickel	155-420
Cadmium	12-53	Copper	58-150	Cobalt	270-311
Zinc	40-50	Iron	176-350	Chromium	500-900

The hardness of Cr deposits depends greatly on the current density. In a bath of 250 g. CrO_3/l. and about 45° C. the following values were obtained:

7

Current density in amp./dm.^{2}	Time in min.	Relative hardness	Current density in amp./dm.^{2}	Time in min.	Relative hardness
16	0.4	1	62	17.5	43
31	2.7	6	78	10.6	26
49	3.8	9	93	9.7	24
			109	9.4	23

The maximum hardness occurred at 62 amp./dm.^{2} It was further stated that beginning with a certain thickness of the deposit the absorption of H becomes less, especially for Ni and Cr deposits. A further factor in the absorption of H is the proper pickling and degreasing. A few practical examples are added to illustrate what is said and to show the harmful influence of H absorption. EF + Ha (7b)

8 **Modern Practice of Copper Electrolysis. (Die heutige Praxis der Kupfer-elektrolyse.)** Georg Eger. *Chemiker-Zeitung*, Vol. 56, June 8, 1932, pages 449-451; June 15, 1932, pages 470-473; June 22, 1932, pages 490-491. A history of the development and review of modern practice of electrolytic Cu production and details of the Wilhelmsburg plant. See also "Copper Electrolysis of the Zinnwerke Wilhelmsburg," *Metals & Alloys*, Vol. 3, May 1932, page MA 129. CEM (7b)

9 **The Electrolytic Refining of Tin at the Mitsubishi Osaka Refinery. II.** Z. Kimura. *Journal Mining Institute of Japan*, Vol. 48, 1932, pages 541-556. Continues previous research (See *Metals & Alloys*, Vol. 3, May 1932, page MA 129). Further studies on the effects of varying the concentrations of cresol sulphonic acid and H_2SO_4 on the electrolysis of the Sn anodes from the Ikuno Mine (concentration of Sn being kept at 4%) are given. Satisfactory results were obtained both as regards the purity of the cathode and the maintenance of the Sn content of the electrolyte when the concentration of the former acid was sufficiently large and that of the latter was less than 4%. When the H_2SO_4 concentration exceeded 4%, the Cu content of the cathode increased and the concentration of Sn ion decreased. The voltage decreased with increasing acid concentration and increased with time of electrolysis, which was not the case with the standard fluosilicic acid bath. In the fluosilicic plus H_2SO_4 mixture, too great an excess of the latter should be avoided. The 2 solutions show no difference in the amount of slime produced. Diminution of Sn ion in the solution during electrolysis depends mostly on the H_2SO_4 concentration. The fluosilicic and H_2SO_4 mixture containing as small amount as practicable of the former is the most economical, but much skill is required in operation. The conditions necessary for obtaining smooth deposits are given. Though gelatine improves the structure of the deposit from both solutions, still better results are obtained by the simultaneous addition of β-naphthol and its presence is essential for obtaining good deposits in the case of prolonged electrolysis. INDUSTRIAL USES & APPLICATIONS (9)

Welded Pipe Lines Installed in Buildings in the United States. LEROY R. GURLEY. *Welding*, Vol. 3, Sept. 1932, pages 538-542. A list of 227 buildings, power and chemical plants, and refineries in which welded piping has been installed during the past year. TEJ (9)

Use of High Test Cast Iron in Machine Construction. (Verwendung von hochwertigem Gusseisen im Maschinenbau.) *Maschinenkonstrukteur-Betriebstechnik*, Vol. 65, Mar. 5, 1932, pages 29-30. The paper particularly refers to the use of alloy cast iron with special reference to nickel cast iron. GN (9)

The Steel Grate Road. A New Road Pavement. (Die Stahlroststrasse. Eine neue Strassendecke.) F. BRUNNER. *Die Bautechnik*, Vol. 10, Sept. 30, 1932, pages 575-578. Description of a new type steel rod road pavement, developed by the "Arbeitsvereinigung Stahlroststrasse, Fohnsdorf, Styria. The pavement is made from steel rods, angles and flats, joined in the intersection points by welding. Steel St. 00.12 is now used. Tests on experimental roads under heavy traffic were most satisfactory. Tests with Cu- steel are in progress. GN (9)

Will the Use of Iron be a Success in Road Building? Cast Iron as Road Pavement. Grate-like Steel Shapes point new Ways. (Wird sich das Eisen im Strassenbau durchsetzen? Gusseisen als Strassenbelag. Rostartige Stahlbau-Elemente weisen dem Strassenbau neue Wege.) ERICH BECKER. *Technische Blätter der deutschen Bergwerkszeitung*, Vol. 22, Oct. 19, 1932, pages 560-561, pages 561-562.

The first paper gives a survey on methods used and suggested in France and England, and deals with 2 German methods, the system Schlechtriem which uses cast Fe bricks and the system Schmidt-Laufach which uses not a continuous cast Fe pavement but honey combed cast iron grates. The costs of the latter method are much less than of any other pavement. The second paper briefly describes the new Austrian method as outlined by Brunner in *Bautechnik*, Vol. 10, Sept. 30, 1932, pages 575-578. GN (9)

Steel as Road Building Material. The Steel Grate Road. (Stahl als Strassenbaustoff. Die Stahlroststrasse.) ADOLF GSTÖTTNER. *Stahlbautechnik*, supplement to *Montanistische Rundschau*, Vol. 24, Oct. 16, 1932, pages 1-5. The paper describes the new type road pavement as previously discussed by Brunner in *Die Bautechnik*, Vol. 10, Sept. 30, 1932, pages 575-578. GN (9)

PV Factor is Not Proper Measure of Bearing Capacity. P. M. HELDT. *Automotive Industries*, Vol. 66, June 1932, pages 842-845. In recent years engine manufacturers have experienced serious trouble with crankshaft bearings. The loads to which engine bearings are subjected increase rapidly with the speed, and speeds have been rising constantly. Together with the tendency towards increased cylinder numbers, the result is that unit pressures on the projected bearing areas have increased sharply. The 2 most important factors in the life of bearings—apart from the lubricant used—are the unit pressure or unit load on the projected area of the bearing, and the surface velocity or rubbing speed. Heat losses vary with the velocity but not with the pressure. As velocity is increased, the maximum permissible unit-load decreases, because the greater loss results in a higher oil temperature and oil viscosity, and thinner oil will not sustain so high a unit load. A curve illustrates the relation between maximum allowable PV and the sliding velocity for different bearing metals. DTR (9)

Special Profiles for Welded Bridges. (Sonderprofile bei geschweissten Brückenbauten.) L. GERSTENBERG. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, Aug. 13, 1932, page 809. Welded lattice work for bridges is reinforced by the use of half I-beams which are split during rolling. Instead of angle iron, flats are often used as reinforcing members. Ha (9)

New Materials for Ore Dressing Machines. (Neuere Werkstoffe für Maschinen der Erzaufbereitung.) E. SEMMLER. *Internationale Bergwirtschaft und Bergtechnik*, Vol. 25, Sept. 15, 1932, page 136. Brief mention of some recently developed non-ferrous alloys. Special bronze "Topal" (free from Zn and Sn) proved highly successful for pumps in the potash industry, special Ni alloys "Admiro 1" and "Admiro 5" were successfully tried for valve seats and valve stems. Admos special bronze "AR" is best for bearings. GN (9)

New Applications of Stainless Metals. C. C. SNYDER. *Refrigerating Engineering*, Vol. 23, Apr. 1932, pages 219-223. A review of the physical and chemical properties of the Cr and Ni-Cr alloys according to type and a detailed table of some 37 applications in the meat packing and allied industries. VVK (9)

Construction Material for Ship Diesel Engines. (Werkstoff-Fragen im Schiffsdieselmaschinenbau.) FR. SASS. *Werft, Reederei und Hafen*, Vol. 13, 1932, pages 64-69. Among the main problems involved in the proper selection of construction material for ship Diesel engines, 4 problems of major interest are singled out referring to the following machinery elements: cylinder cover, piston, cylinder journal bearing sleeve and piston rod. EF (9)

Electro-welded Steel Masts for Over-head Lines. (Elektrisch geschweisste Stahlgittermasten für Überlandleitungen.) H. G. SCHWEPPENHÄUSER. *Elektrizitätswirtschaft*, Vol. 31, Feb. 29, 1932, pages 92-93. The advantages of welded masts in comparison with riveted ones are pointed out. The necessity for properly trained construction engineers and executives is stressed. The genuine tests of the Deutsche Werke Kiel A.G. on an order of 108 masts of 20 m. height are described and illustrated. The top of the masts showed a 48 cm. elastic deflection when being stressed to 1.5 times the maximum permissible load. Data on the design of the welded masts for the 60 kv. transmission line Kiel-Neumünster are presented. The savings in weight due to the adoption of welding amounted to 8%. EF (9)

Welding makes New Type Tanks Possible. WM. REED-HILL. *Industry & Welding*, Vol. 4, Sept. 1932, pages 8-12. The construction by welding of big double-shelled tanks for the storage of oil or volatile liquids with or without provision of heating or cooling by steam, air or water is described. Special advantages of welded tanks are a perfectly smooth interior which reduces cleaning cost to a minimum, no leaks or seepage, no gases to ignite, entire absence of fire risk and evaporation; insurance at reasonable rates; greatly reduced corrosion. The shells can be of Fe or steel. Ha (9)

Springs and Spring Steel. *Engineering*, Vol. 132, Dec. 25, 1931, page 795. Abstract "Report of Springs Research Committee" Department Scientific & Industrial Research. See *Metals & Alloys*, Vol. 3, June 1932, page MA 172. LFM (9)

Contribution on the Calculation of the Bending Stresses in Cable Wires of Aerial Tramways. (Ein Beitrag zur Berechnung der Biegespannungen in den Kabeldrähten von Seilbahnen.) U. R. RUEGGER. *Schweizerische Bauzeitung*, Vol. 99, Mar. 5, 1932, pages 120-121. Problem is solved by simple elementary methods. GN (9)

Concrete Columns with Large Bars Offer Advantages. THOR. GERMUNDSSON. *Engineering News-Record*, Vol. 109, Sept. 8, 1932, pages 277-278. Columns with a high percentage of 2″ bars save material, floor area and cost over columns designed under codes limiting steel percentage to 6 and bar sizes to 1¼″. The large bar column compares favorably with structural steel encased in concrete. CBJ (9)

Nickel Steels and Alloys in Shipbuilding. (Les aciers et alliages au nickel dans les constructions navales.) JEAN GALIBOURG. *Revue du Nickel*, Vol. 3, Apr. 1932, pages 34-51. A detailed description of the uses of Ni and its alloys in shipbuilding. The compositions of the various alloys are given with their proper and actual use on ships. AH (9)

The Lightening of 300 Suburban Railway Carriages by the Use of Light Alloys. (Allegement de 300 Voitures de Banlieue par l'Emploi des Alliages Legers.) A. DUMAS. *Revue de l'Aluminium*, Vol. 8, No. 42, 1931, pages 1364-1370. By substituting Al and Al alloys (duralumin, alpax and an alloy containing Cu 2%, Mn 2% and Ni 2%) for certain steel parts of railway carriages, it has been found possible to decrease the weight of the wagons by nearly 6%. Details of construction for roof, doors, window sashes, etc., are illustrated. Ha (9)

The Stresses in Boiler Tubes of Modern Highly Stressed Boilers. (Die Spannungen in Kesselrohren neuzeitlicher Hochleistungskessel.) K. ADLOFF. *Die Röhrenindustrie*, Vol. 24, July 30, 1931, pages 181-182; Aug. 13, 1931, pages 193-194; Aug. 27, 1931, pages 207-208. The fundamental equations covering the calculation of boiler tube stresses are presented and the modifications in design due to the new trends in boiler construction are considered. Emphasis is placed on the tendency toward reducing the tube diameter, increasing the water circulation speed, and reducing the wall thickness so as to cut down the temperature differences and to raise the cooling effect. The improvement of the heat transfer in the highly stressed boilers with small sized tubes is discussed. The stresses occurring are graphically presented and the problem of the stress increase at those parts where the tubes are rolled in, is dealt with. EF (9)

Light-Weight High-Pressure Gas Cylinders. FRANK S. MARSH. *Iron & Steel Institute, Advance Copy* No. 8, Sept. 1932, 13 pages. Small gas cylinders were made from 2 types of Ni-Cr-Mo steel and heat treated. The results of a series of destructive tests described in the article proved that light-weight, high-pressure cylinders can be manufactured to withstand rough handling. The cylinder walls were 0.2″ thick. The cylinders were heat treated to give a tensile strength of approximately 60 tons/in.² and an elongation of 20% in 2″. JLG (9)

Uses of Nickel in Artillery. (Le Nickel dans les fabrications d'artillerie.) MALAVAL. *Revue du Nickel*, Vol. 3, Apr. 1932, pages 52-54. A description of the uses of plain Ni steels, cupro-nickels and stainless steels in artillery constructions and equipment. AH (9)

Two-Ply Stainless Steel Automotive Parts Manufacturing. S. L. INGERSOLL. *Automotive Industries*, Vol. 67, Sept. 24, 1932, pages 392-393. For almost 10 years research has attempted to produce a combination metal. This combination metal was to be used for the central element of wooden spoke artillery type wheels, automobile body hardware and bumpers. A 2-ply stainless clad metal was the apparent solution to the problem, but no successful method was evolved which would assure a perfect weld between the stainless surface and the base metal on a large tonnage basis. The present process of producing 2-ply stainless steel is described. The sheets or plates may be deep-drawn, stamped, formed, welded and highly polished. It is adaptable to welding by gas or electro-welding methods. The character of the 2-ply metal limits its use to those applications where a continuous surface is exposed to corrosion, heat or abrasion. DTR (9)

Steel Use in Marine Construction. (Stahlverwendung bei Marineanlagen.) JUSTUS HORN. *Stahlbautechnik*, supplement to *Montanistische Rundschau*, Vol. 22, Oct. 16, 1932, pages 6-8. The paper discusses the use of steel for frames in dockyards, jetties, gangways, roofs and walls of yard buildings, etc. GN (9)

Ribbed Tubes in Boiler Units. (Rippenrohre im Kesselbetrieb.) H. D'HUART. *Die Wärme*, Vol. 55, Jan. 9, 1932, pages 17-21; Jan. 23, 1932, pages 52-55. The abundantly illustrated paper historically reviews the evolution of ribbed tubes and fully considers their utilization in combustion chambers, boilers, economizers, super-heater and air heating units. EF (9)

The Introduction of Gallium into Technique. A Metal that melts at 30°C. (Einzug des Galliums in die Technik. Ein Metall, das bei 30°C. schmilzt.) W. HERZOG. *Die Umschau in Wissenschaft und Technik*, Vol. 36, Mar. 12, 1932, page 206. Ga, discovered spectro-analytically in 1875, stands between Al and Zn, melts at 30° C., volatilizes at 2000° C., cost 175 RM/g. in 1931 and now about 9 RM/g. is produced by the Vereinigte Chemische Fabriken Leopoldshall, which also distribute Re at a greatly reduced price. Tests are performed in the Physikalisch-Technische Reichsanstalt with the object of replacing Hg by Ga. Since it is not poisonous, Ga was successfully experimented with in dental alloys. It furthermore offers a valuable substitute for Hg in quartz analysis lamps due to its wider range of radiation frequency. Further tests are under way using Ga as foil for optical mirrors, electric fuses and signal instruments. EF (9)

Light Structural Profiles Made of Hoop Steel. (Leichtprofile aus Bandstahl.) LEOPOLD HERZKA. *Montanistische Rundschau, Stahlbautechnik*, Vol. 24, Sept. 16, 1932, pages 1-4. The results of tensile tests, bending tests and buckling tests are discussed; the experiences gained with such profiles in Austria are reported. GN (9)

Renewable Valve Seats Cut Maintenance Cost by Eliminating Necessity for Periodic Regrinding. P. M. HELDT. *Automotive Industries*, Vol. 65, Nov. 21, 1931, pages 794-796. The use of valve inserts is recommended to combat increased wear and erosion on valve-seats in the modern commercial vehicles. The method of insertion is described and shown diagrammatically. The material of a valve insert must have approximately the same coefficient of expansion as the metal of the block. In addition it must be able to withstand high temperatures and it must not soften materially at high temperatures. It is also considered advantageous to have a seat of a different material from that of the valve itself. Materials in favor are Al-bronze for light alloy pistons, and Stellite, W-Cr-V-steel, or a high-speed W-alloy for engines intended for heavy duty. DTR (9)

Properties of Metal Foil as an Insulating Material. J. L. GREGG. *Refrigerating Engineering*, Vol. 23, May 1932, pages 279-283; discussion, pages 283, 290, 304. An investigation to determine the feasibility of using Al foil as an insulating material gave results as follows: A rigid unit formed by foil sheets held ½″ apart by wooden separators was found to weigh less than 3 lbs./ft.³ and to have a thermal conductivity for an average temperature, 100° F. of 0.24 to 0.25 B.t.u. The emissivity of commercial Al foil with respect to room temperature radiation was approximately 5% that of the black body. The emissivity did not change appreciably with age except when the sheets were exposed to the most corrosive conditions. VVK (9)

Flexible Copper Tubing and Its Fabrication. (Die biegsame Kupferröhre und ihre Fabrikation.) W. GREINER. *Apparatebau*, Vol. 43, Dec. 24, 1931, pages 301-302. Description of the manufacturing process of flexible Cu tubings. GN (9)

German Cast Iron Road, System Schmid-Laufach. (Deutsche Gusseisenstrasse, System Schmid-Laufach.) OTTO LEITOLF. *Die Giesserei*, Vol. 19, July 22, 1932, pages 288-290. Cast Fe plates of about 1/3 m.², one side smooth, the other honey-combed were laid on a bed of usual road material and the honey combs filled with brick splits and tar, and tamped. The road is not slippery and behaved well during 1½ years of operation. Ha (9)

Notes on the Adoption of Alloy Steels as Boiler Material. (Einige Bemerkungen über die Einführung von Sonderstählen als Werkstoffe für Dampfkessel.) E. LUPBERGER. *Elektrizitätswirtschaft*, Vol. 30, Apr. 1931, pages 223-226. Higher pressures and temperatures commanded the development of new steels for boiler construction. Several impartial German research institutes studied the material offered by industry from 10 different view-points. The particular usefulness of low C, Mo and Cr-Mo steels was established. The new possibilities in the construction of power plants due to the newly adopted alloy steels are summarized. EF (9)

Designing Welded Vibrating Equipment. ASHER H. PATTEN. *Industry & Welding*, Vol. 4, Sept. 1932, pages 2-7. The stresses occurring in equipment or machine parts which have to carry out vibrating motions, as for instance screens, shaking conveyors, etc., are discussed and the failures of constructions of wood and Fe reviewed. Some new constructions of welded parts are described which have stood up well under actual operating tests. Ha (9)

Science Unveils the Mystery of the Razor Blade. J. G. PRATT. *American Photography*, Vol. 26, Sept. 1932, pages 520-524. Experiments with many types of blades showed heavy type blades can give much longer service than thin blades as they can be stropped after they have been dulled, while thin blades do not stand stropping often. Blades from which the waxy substance is removed soon begin to corrode. Ha (9)

Nickel Steel in Bridge Building. (Der Nickelstahl im Brückenbau.) F. Bohny. *Bauingenieur*, Vol. 13, Jan. 1, 1932, pages 15-18; Metzler. *Bauingenieur*, Vol. 13, July 1, 1932, page 373. The paper first gives a survey on the use of 3½% Ni-steel for bridge building in U.S.A. before the World War. The first Ni-steel bridges in Germany were built by the Gutehoffnungshütte and the Krupp Works from 1908-1911 from 2-2½ Ni-steels. This lower Ni content was chosen due to high costs. The American tensile specifications are given. The advantages of Ni-steels are pointed out. The total of all physical properties including fatigue properties and economic considerations finally decides the selection of steels for bridge building. GN (9)

Present State of Construction of Welded Bridges. (Etat Actuel des Constructions de Ponts Soudes.) H. Michel. *Revue Universelle des Mines*, Vol. 7, Series 8, Apr. 1, 1932, pages 372-373. The paper gives a complete enumeration of the 34 welded bridges which have been built since 1922. It gives their manufacturer, the welding process applied, span, width, weight and type, and purpose. The longest span, 1045 ft., is being built now in Dresden. Ha (9)

The Use of the Eloxal Process in the Textile Industry. (Die Anwendung des Eloxalverfahrens in der Textil-Industrie.) *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 4, Apr.-June 1932, page 111. Eloxal-treated Al parts have proved their value. Where great hardness is required they have been advantageously employed. Ha (9)

The Importance of the Eloxal-Process for Fire Departments. (Die Bedeutung des Eloxal-Verfahrens für das Feuerwehrwesen.) W. Sternberg. *Aluminium, Hauszeitschrift V.A.W. und Erftwerk*, Vol. 4, Apr.-June 1932, pages 114-115. Corrosion resistance and lightness and especially a heat-radiation capacity which approaches closely the black body, and further its good heat conductivity have made eloxated Al an excellent material for ladders, hydrants, coupling, wrenches, etc., in the machinery of fire departments. Ha (9)

Increase of Efficiency of Combustion Motors by Treatment of the Pistons. (Erhöhung des Wirkungsgrades von Verbrennungsmotoren durch Behandlung der Kolben.) *Aluminium, Hauszeitschrift V.A.W. und Erftwerk*, Vol. 4, Apr.-June 1932, page 109. Surface hardening with Eloxal of the Al pistons is a very good means to lengthen the life of cylinders. The Al pistons can be more easily and more cheaply renewed. Ha (9)

Increase of Capacity of Electric Induction Furnaces. (Erhöhung der Leistungsfähigkeit von elektrischen Induktionsöfen.) *Aluminium, Hauszeitschrift V.A.W. und Erftwerk*, Vol. 4, Apr.-June 1932, page 110. The coating of Al conductors with Eloxal makes possible the production of a hard, firmly adhering insulating layer which melts only at a temperature much higher than the conductor. As these layers take much less space than other insulating materials and are not sensitive to temperature, power factor and efficiency are favorably influenced by their use. Ha (9)

The Importance of the Eloxal Process for the Construction of Condensers. (Die Bedeutung des Eloxalverfahrens für den Kondensatorenbau.) *Aluminium, Hauszeitschrift V.A.W. und Erftwerk*, Vol. 4, Apr.-June 1932, page 110. Eloxal-coated Al foils make excellent material for building of condensers due to great uniformity of structure and thickness of the coating. Ha (9)

Beryllium Alloys for Springs, etc. (Berylliumlegierungen für Federn und degl.) *Apparatebau*, Vol. 44, Sept. 16, 1932, pages 129-130. D.R.P. 529 945 covers the addition of Be to Fe, Cu, Ni, invar, elinvar and similar alloys. For helical springs of Cu, Ni or elinvar 1-2.5% Be are added, finest springs requiring the larger amount of Be. The static and dynamic properties of a few Cu-Be alloys are discussed and compared with those of P-bronze, brass, German silver as applied to springs. The vast superiority of the new alloys is evident. Be bronzes with .9%-1.5% Be are used as bearing metals and show about 1/6 of the wear of Sn bronzes. The procedure in aging 2.5% Be-Cu alloys is discussed. Soldering non-aged Cu-Be alloys offers no difficulties, however, heating above 300° C. is to be avoided. Upon brazing, Cu plating the joint (.05-.1 mm. thick) is advisable. The following pickling solutions are given: 1 part of a solution of 5 g. $KMnO_4$ in 100 cc. H_2O to 9 parts of dilute H_2SO_4 (1 part H_2SO_4 66° Bé to 9 parts H_2O). Another solution is made by adding 1-6 parts of H_2O_2 solution (1 part of 30% H_2O_2 to 2 parts of H_2O) to 100 parts of diluted H_2SO_4. Pickling requires 1-2 hrs. After pickling the parts are lightly brushed. GN (9)

New Alloys. (Neue Werkstoffe.) *Kali, Erz und Kohle*, Vol. 29, Aug. 10, 1932, pages 128-129. The paper deals with properties and application of various Be-alloys after having first given a brief account of the electrolysis of Be as developed by the only European manufacturer of Be, the Siemens Co., Berlin. Ni-Be, Fe-Be and Cu-Be alloys with special reference to Be bronzes are discussed. Be bronzes show low fatigue and high elasticity, to make them most adaptable to all kinds of springs. In many cases where corrosion-resistant and non-magnetic alloys are required steels are suitably replaced by Be-bronzes. Ni-Be alloys possess a high resistance against sea water and attain great hardness by aging. For this reason such alloys are used as hollow needles, tubules and surgical instruments. Special Be-steels have been developed on Cr-Ni base. GN (9)

Chromium Plating Instruments and Tools. (Die Verchromung von Mess-und Arbeitswerkzeugen.) *Chemiker-Zeitung*, Vol. 56, Aug. 10, 1932, pages 629-630. It is recommended to plate calipers, scales, gages, etc., with .005 to .015 mm. Cr. After plating they should be heated for 20 minutes at 200° C. to drive off H_2 occluded during plating. CEM (9)

Cast-Iron Grid Road Surface. *Engineering News-Record*, Vol. 109, Sept. 29, 1932, page 383. Cast Fe grids, the openings of which are filled with asphalt mastic or other surfacing material, are being built in Germany. Advantages are listed. CBJ (9)

Copper Roofs. (Les Toitures en Cuivre.) *Cuivre et Laiton*, Vol. 5, Aug. 15, 1932, pages 343-351. A detailed description is given of the general properties of Cu, especially those of importance when used for roofing, and compared with other metals (Zn and Pb). The methods of joining Cu sheets, water-proofing of roofs and joints, details of construction are explained and illustrated. Ha (9)

Steel for Interior Decoration of Passenger Cars. (Stahl bei der Innenausstattung von Personenwagen.) *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 86, Feb. 1, 1931, page 108. The utilization of steel for railroad coaches is not restricted to the under- and superstructure. The interior equipment of parlor cars, dining and sleeping cars can be made of steel instead of mahogany or other high-grade woods. The fiber structure can be truly imitated and the pattern of marble can also be perfectly copied on steel. Steel furniture can easily be shaped, is clean and fire-proof. EF (9)

Aluminum in Armored Electric Cables. (L'aluminium dans les cables electriques armés.) *Radioélectricité et QST Francais*, Paris, Vol. 11, Dec. 1930, pages 28-30. Information on composition, conductor material, insulation resistance and disruptive strength. Excessive voltages and currents, laying qualities. Cu and Al conductors are compared economically. Note on armoring. GG (9)

Utilization of Aluminum and Light Metals as Railroad Material. (Die Verwendung von Aluminium und Leichtmetallen beim rollenden Material.) *Organ für die Fortschritte des Eisenbahnwesens*, Vol. 87, Feb. 1, 1932, page 74. There are 65 Al casting and 25 forging Al alloys on the market. The utilization of light metals was started in 1923 in the U.S.A. (Illinois Central, Pennsylvania Railroad and Chicago & North Western Railroad). The use of Al is specially recommended for tank cars. Recently Al light metal drawbars and reversing valve rods were introduced. The savings in weight due to replacing steel by Al amounts to 1-15%, occasionally to 35%. Data from 10 different companies showed 18-60% savings in weight and 14-43% savings in power. Each kg. saved due to the utilization of light metals required 1.45-2.25 R.M. (1.85 average) additional expenses. The latter are amortized in 3-4 years. The scrap metal value of light metals is 40-60% of the initial cost. EF (9)

The Metals of Oil-Engine Construction. *Power*, Vol. 76, Sept. 1932, pages 115-117. Diesel frames and cylinders with separate liners are cast of Fe, steel or Al or are fabricated of welded steel. Cylinders without liners are cast Fe. Cylinder liners are cast Fe, steel or hardened Nitralloy. Ni-Resist cast Fe is used for liners in Al cylinders because its coefficient of expansion is about the same as Al. Cylinder heads are usually cast Fe; steel is used on larger units and Al in smaller. Cast Fe is the usual piston material; Al is used in small high-speed units. Piston rods are made of straight C or Ni-Mn steels. Rings are Si cast Fe. Hardened tool steel pins or nitrided and Cr-plated pins are used. Crankshafts are C steel forgings. Bearings are Sn-base alloys, or, for higher temperatures, leaded bronzes. AHE (9)

Provisional Acceptance Conditions for Valve-Steels for Aircraft Engines. (Conditions provisoires de reception relatives a la fourniture des aciers a soupapes pour moteurs d'aviation.) *Service des Fabrications de l'Aeronautique*, Vol. 30, Aug. 1930, 12 pages. This booklet contains the standards for valve steels. The required chemical analyses and physical properties are given with the relative tolerances. In addition, directions for carrying out the tensile test on valves is given. Following alloys are specified: Ni-Cr, Cr-V, Cr-Si-Mo, Co-Cr-Mo, Ni-Cr-W. GG (9)

Light Alloys Save Weight for 300 Suburban Railway Carriages. (Allégement de 300 voitures de banlieue par l'emploi des alliages légers.) *Revue de l'aluminium et de ses applications*, Vol. 8, Mar.-Apr. 1931, pages 1364-1370. Aluminum, duralumin, alpax (Sand cast) and a 2% Cu, 2% Mn, 2% Ni aluminum alloy replaced steel in certain parts of railway carriages. This substitution permitted the Chemin de Fer de l'Etat in France an increased efficiency of 12.5%. AH (9)

Large Freight Cars of Aluminum. (Grossraum-Güterwagen aus Aluminium.) Wernekke. *Aluminium*, Vol. 14, June 30, 1932, pages 4-5. Describes the cars built by the Aluminum Co. of America, 70 tons capacity, weight 17.7 tons against 27.2 tons for the same car of steel. One car contains about 5.7 tons of Al in the shape of sheets, forged and cast parts. Besides saving in weight the resistance against corrosion was an important consideration for their construction. Ha (9)

Entirely Welded Floating Pile Driver. (Vollkommen geschweisste Schwimmramme.) O. Wundram. *Zeitschrift Verein deutscher Ingenieure*, Vol. 76, Mar. 19, 1932, pages 293-294. Detailed description of construction and power installation of a pile driver for 130 blows per minute, 2000 mkg. Ha (9)

Vanadium Steel for High Speed Machine Tools. (Vanadiumstahl für Werkzeugmaschinen mit hoher Umdrehungsgeschwindigkeit.) *Die Werkzeugmaschine*, Vol. 36, Sept. 30, 1932, page 344. High V- high C tool steels show excellent machining properties at high speed without decreased toughness. V varies between 3.8-6.5%, C between 1.2-1.7%. Similar steels are C-V-Co steels. The favorable properties of V tool steel are probably due to a fine grain and the highly dispersed carbides. GN (9)

The Use of Castings in Welded Structures. J. G. Ritter. *Steel Founder*, Vol. 3, Mar.-Apr. 1932, pages 21-24; *Journal American Welding Society*, Vol. 11, Mar. 1932, pages 2-29; *Welding*, Vol. 3, July 1932, pages 423-424; *American Machinist*, Vol. 76, Feb. 4, 1932, page 167; *Machine Design*, Vol. 4, Mar. 1932, pages 40-41. Paper presented before a meeting of the Steel Founders' Society of America, in Chicago. See also *Metals & Alloys*, Vol. 3, Oct. 1932, page MA 300. Ha+TEJ+RHP (9)

On the Possibilities of Development of Steel Frame Buildings in Middle Europe. (Über die Entwicklungsmöglichkeiten der Stahlskelettbauten in Mitteleuropa.) Johann Tille. *Stahlbautechnik* supplement to *Montanistische Rundschau*, Vol. 24, Oct. 16, 1932, pages 5-6. The paper discusses the difficulties in constructing steel frame buildings in Austria and Czecho-Slovakia. GN (9)

Advances in Modern Railway Passenger Coach Construction of the German States Railway. (Entwicklung neuzeitlicher Eisenbahnpersonenwagen bei der Deutschen Reichsbahn.) Stroebe & Wiens. *Organ für die Fortschritte des Eisenbahnwesens*, Fachheft "Personenwagen," Vol. 87, Feb. 1, 1932, pages 21-40. The abundantly illustrated paper gives a most complete account of the latest advancements in German railway car construction. The interest of the metallurgist is in the chapters "Fundamental Differences between Wood and Steel Construction," "Municipal Railway Cars of Light Metals" (City Express Coaches), "Light Metal Construction Applied to Regular Railway Coaches" and "How can the Low-weight Construction be Achieved?" EF (9)

Copper-Silicon Alloys, New Material for the Construction of Apparatus and Machines. (Kupfer- Silizium- Legierungen, neue Werkstoffe für den Apparate- und Maschinenbau.) Erick Becker. *Apparatebau*, Vol. 43, Oct. 16, 1931, pages 241-242. Survey on Cu-Si alloys to be used for the mentioned purpose. Binary Cu-Si alloys are a high quality substitute for binary Cu-Sn alloys. Alloys with 3.7-6.7% Si can be improved by aging and are used as rolled products. For castings alloys with 2.5-4.5% Si with about 2% Zn are best. Improved binary Cu-Si alloys are distinguished by high corrosion resistivity. Casting alloy Everdur 50 is most adaptable to armatures. Isima bronzes contain Cu, Si, Mn. Corson alloys, containing Cu, Si, Cr, Fe, Ni or Co are best fitted for thin-walled vessels and containers of chemical industry. Tombasil contains 3-5% Si, 10-18% Zn in addition to Cu and its tensile strength decreases but slightly up to 300° C. (20° C.: tensile strength 64.3 kg./mm.², elongation 19%; 300° C.: tensile strength 59.1 kg./mm.², elongation 16.8%). This alloy is particularly adaptable to thin-walled castings. Its corrosion properties are similar to that of Cu. GN (9)

Aircraft Engine Steel. N. L. Deuble. *Paper presented before the American Society of Mechanical Engineers*, Aeronautic Division, Buffalo, June 1932. 7 pages. In making steels for use in aircraft engines great care is exercised in all manufacturing operations. They are inspected microscopically and microetched. Charts of steels at 100 mag. have been made up and are used as standards. Specifications of 4 manufacturers for the steel used in crankshafts, the most vital and highly stressed part of an aircraft motor are given. Steels made by electric furnace and open-hearth methods can both give equally good results; the electric furnace is capable of closer control of slag conditions, temperature and atmosphere and can give a sounder, denser and more uniform product from heat to heat. Nitralloy steels are used for gears and wrist and link pins which are subjected to great shearing stresses. Nitriding steels, both Cr-Mo and Cr-V types are being investigated for probable use, also a Cr-Ni-Mo steel with a core-hardness of 30-34 Rockwell C and case hardness 60 Rockwell C after normalizing; the latter type will be particularly suitable for gears and intricate parts now carburized and hardened with difficulty. Due to the great improvement in materials and design the life of an aircraft engine has been lengthened from about 80 hrs. 15 years ago to 1500 hrs. and more at present. Ha (9)

The Heat Treatment and Use of Aluminum Alloys for Aircraft Structures. Part II. Robt. J. Anderson. *Fuels & Furnaces*, Vol. 9, Dec. 1931, pages 1375-1380. Al alloy tubes, stampings, sheets, etc., are assembled by riveting. Alclad sheeting (0.0095" thick) for dirigibles is sewed together by automatic riveting machines. Al parts are heat treated either before or after assembly. Heating to temperatures just short of melting or distortion causes solid solution of the hardening constituents ($CuAl_2$ or Mg_2Si). Quenching at 500° to 530° C. produces a supersaturated solution, the metal then being rather soft. Aging for from a few hours to 6 or 8 days at room temperatures or warmer (e. g. 100° C.) causes a great increase in hardness and strength due to the crystallizing from solid solution of the hardening constituents in a very finely divided state. Selection of exact temperatures and times for quenching and aging depends on the chemical composition of the alloy, whether it is wrought or cast, the mechanical properties desired, the size, shape and mass of the parts, the nature of previous forming operations, and whether heat treatment precedes or follows assembly. CMB (9)

HEAT TREATMENT (10)

Quenching (10d)

Oils Used in Heat Treating Plants. (Beitrag zur Frage der in Wärmebehandungsbetrieben zu verwendenden Oele.) K. KREKELER & F. RAPATZ. *Petroleum*, Vol. 28, Apr. 1932, pages 4-7. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 309. EF (10d)

The Use of Oil as a Quenching Medium in Heat Treating. *Lubrication*, Vol. 18, Apr. 1932, pages 37-42. After a brief discussion of the purpose of quenching and some other mediums used the advantages of oil of animal or vegetable nature are discussed. The effect of the viscosity of an oil on the quenching speed is of great importance. The principal requirements of a quenching oil are set forth as follows: (1) Must be capable of developing fairly high quenching speeds uniformly over a relatively wide range of temperatures, that is, at least 100°. (2) It must be as free as possible from volatile constituents in order to insure stability and preclude change in viscosity or body due to excessive evaporation under the high temperatures frequently involved. (3) It must be easily removed from the steel being quenched and (4) be able to retain its quenching power and other characteristics over a suitable length of time. The purification of quenching oils and the removal of C forming in it are described. Ha (10d)

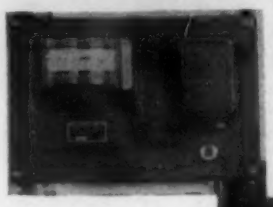
On the Hardening Effect of Repeated Quenching in Carbon Steels. SHOZABURO NANAO. *Kinzoku no Kenkyu*, Japan, Vol. 9, May 1932, pages 197-206. It is well known that when imperfectly quenched steels are re-quenched from the same temperature a severe quenching effect is obtained. A method of avoiding the bad effect was investigated by means of magnetic measurement, Charpy impact test, electric resistance measurement and microscopic examination. The results obtained were that: (1) The re-quenched steels contain some retained austenite and the degree of magnetization is lowered; the impact and the electric resistances are increased. (2) If a steel quenched from the proper temperature was annealed at higher temperature and cooled in furnace, it contains much sorbite. (3) When this sorbitic steel was quenched at the same temperature, a small amount of austenite was retained. This was proved by magnetic analysis, the impact test and the electric resistance measurement. (4) To obtain a normal structure by annealing a quenched steel, the cooling rate of the steel must be much slower than the furnace cooling. If the steel treated as mentioned above and having normal structure is quenched again, perfect quenched structure is obtainable. KT (10d)

Oils in Heat Treating Operations. (Oele in Warmbehandlungsbetrieben.) K. KREKELER. *Elektrowärme*, Vol. 2, Feb. 1932, pages 33-36. The oils used for the hardening of steel were investigated; they are divided into (1) hardening oils, (2) tempering oils. For the first group mineral oils and fat oils are equally suitable. The heat must be absorbed so quickly that even large pieces are sufficiently hardened into the interior. The evaporation must be slight, the ignition point as high as possible. For blank-hardening special oils must be used. 3 grades are given. On account of the high ignition point required for tempering oils only cylinder oils can be used which must have a low content of asphalt. The compositions of a few oils are given. Ha (10d)

The Effects of Water Quenching on Soft and Extra-Soft Steels. Aging after Quenching. (Effects de la Trempe a l'Eau sur les Aciers Doux et Extra-Doux. Vieillissement apres la Trempe.) J. SEIGLE. *Revue Technique Luxembourgeoise*, Vol. 24, Mar.-Apr. 1932, pages 50-59. The observation that mild C steel of about 40 kg. tensile strength if heated to more than 600° C. and quenched in water behaves quite differently from other mild steels of greater resistance, especially the phenomenon of aging after quenching, was further investigated. The tests made and the methods used in the tests are described in detail; the results are discussed and explained by the Fe-C diagram. A quenching temperature of 700° C. had the most favorable effect on the tensile strength; directly after quenching it was about 50 kg./mm.^{2} and after one month had increased to 70 kg./mm.^{2}. Sometimes a steel so treated shows a great sensitivity to impact, but this can be eliminated by reheating to 225° C. See also "New Results of the Influence of Quenching in Water on Mild Steels," *Metals & Alloys*, Vol. 3, Nov. 1932, page MA 326. Ha (10d)

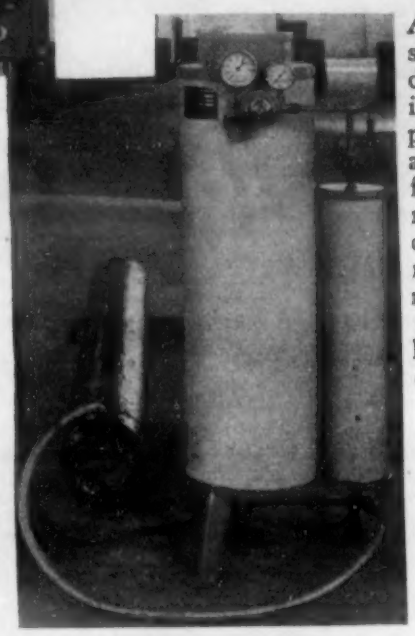
Aging (10f)

Hardness Change of Duralumin with Time and at Different Depths. FRANZ BOLLENRATH. *Metals & Alloys*, Vol. 3, May 1932, pages 120-126. Data is presented showing hardness values at various depths and their change with time of aging of quenched duralumin. Brinell and Rockwell hardness tests appear to give an average value for an appreciable depth but the Herbert pendulum time-hardness gives a value more nearly that of the surface tested. The maximum hardness values are attained at a depth of 0.4 to 0.8 mm. The author explains this on the basis of rate of cooling during the quench. At different depths the rate of cooling will be different and with the temperatures employed by the author, 500° to 530° C., a water quench seems to produce a supersaturation condition at this depth that is right for the production of highest hardness. 19 references. WLC (10f)



Form of the Tension-Elongation Curves on the Basis of Measurement of the Temporary Course of Aging of Soft Steel. (Zur Kenntnis der Form der Spannungs-Dehnungs-Kurven auf Grund der Messung des Zeitlichen Verlaufes der Alterung weichen Stahles.) WERNER KÖSTER, HANS VON KÖCHRITZ & ERNST HERMAN SCHULZ. *Archiv für das Eisenhüttenwesen*, Vol. 6, Aug. 1932, pages 55-60. Report 184 of Committee on Materials of Verein deutscher Eisenhüttenleute. The temporary changes in some mechanical properties of a 0.10% C open hearth steel were noted after a preliminary stretching of the material. The steel was stretched 5, 10 and 18% at temperatures from 20° to 350° C. and the changes in mechanical properties observed over a period of 3 months. Before being stretched the original steel samples were bars 10 mm. diam. and 100 mm. long. These bars were annealed at 930° C. for ½ hr. and then stored for 14 days at 100° C. giving a very uniform structure equilibrium. The higher the annealing temperature, the more rapid the increase in elastic limit and tensile strength, and also the quicker the decrease in elongation. With a temperature of 100° C. and less the properties pass through a maximum or minimum value, followed by a drop or rise. While the tensile strength, elongation and reduction of area varied with approximately similar rates, the elastic limit varied at a greater rate than that of the tensile strength. By this difference the course of the isotherms of the elastic limit ratio and the length of the flow range for the elastic limit are determined. At low annealing temperatures, particularly, these show sharp maximum values. If the elastic limit ratio is not raised fully 100% by greater stretching, then it may rise above 100% during aging as a result of this rate differential. The difference in rate means that the elastic limit (end point of the curve of elastic expansion) becomes greater than the tensile strength. In such a case the elongation of the steel becomes very small. DTR (10f)

A Special Method of Notched Bar Testing used for Comparison of Aging Tendencies of Steels. (Eine besondere Ausführungsform des Kerbschlagversuches angewendet für den Vergleich der Alterungsempfindlichkeit von Stählen.) R. WALZEL. *International Association for Testing Materials, Zurich Meeting, 1931*, Vol. 1, 1932, pages 405-408. An impact specimen is compressed 10% and then aged by heating 2 hrs. at 250° C. in order to show aging embrittlement. Characteristic embrittlement curves are shown. HWG (10f)



The Age-Hardening of Some Aluminum Alloys of High Purity. MARIE L. V. GAYLER & G. D. PRESTON. *Journal Institute of Metals*, Vol. 48, 1932, pages 197-219. Includes discussion. See *Metals & Alloys*, Vol. 3, Nov. 1932, page MA 327. (10f)

Evolution of Pressure Vessels to Meet Present-day Refining Pressures and Temperatures. H. LEROY WHITNEY. *Transactions American Society of Mechanical Engineers*, Vol. 54, 1932, Petroleum Mechanical Engineering, pages 27-30. Review of welding and riveting methods for manufacturing pressure vessels and the outlook for further improvements. Ha (11)

On the Combined Effect of Riveting and Welding with Regard to the Conditions of Initially Loaded Rivet Joints and Joints Reinforced by Welding under Initial Load. (Über das Zusammenwirken von Nietung und Schweissung unter Berücksichtigung der Verhältnisse vorbelasteter und unter Vorlast durch Schweissung verstärkter Nietanschlüsse.) O. KOMMERELL & G. BIERETT. *Die Bautechnik*, Vol. 10, Sept. 23, 1932, pages 566-572. The following tests were made: (1) static tensile and alternating tension fatigue test on riveted joints, (2) static tensile test on welded joints, plates and laps provided with rivet holes, (3) riveted joint, loaded with 12.3 tons, unloaded then welded and static tensile strength determined, (4) 2 riveted joints treated as under (3), but after loading load released only to 6 tons, welded under this load, static and dynamic tensile strength determined. The tests also comprise temperature measurements on rivets during welding and extension measurements on rivets during initially loading. From the latter tests the stress distribution was calculated. The maximum temperatures in the rivets amounted to 200° C., i.e. loosening of rivets during welding need not be feared. The static and dynamic tensile properties are in good accordance, thus indicating that static tests on such joints, proper arrangement and sufficiently fine measurements provided, are a satisfactory yardstick for permissible loads also as regards fatigue properties. The tests prove combination of riveting and welding to be successful unless the riveted joints are in improper condition. About 53% of the load was carried by the rivets, about 47% by the welds. The resistances to deformation of rivets and welds should be approximately alike. Loose rivets are to be replaced before welding. The tests justify the calculation methods, assuming 1/3 of the load to be carried by the rivets and 2/3 carried by the welds. GN (11)

Gives Rules for Gas or Arc Welding Rustless Steel. L. W. HOSTETTLER. *Iron Age*, Dec. 31, 1931, pages 1689, 1692. Abstract of paper read at the National Dairy Exposition. See "Allegheny Metal in Dairy Equipment," *Metals & Alloys*, Vol. 3, Oct. 1932, page MA 305. VSP (11c)

Electrically Welded Sheet Beam. (Elektrisch geschweisster Blechträger.) A. U. HUGGENBERGER. *Schweizerische Bauzeitung*, Vol. 98, Dec. 26, 1931, pages 338-341. Results of tensile tests on electrically welded sheet beams without reinforcing fish plates. Upon loading the beams elongation and deflection were measured with a tensometer. Measured results and calculation show good accordance. GN (11c)

The Metallurgy of Welds. J. C. HOLMBERG. *Journal American Welding Society*, Vol. 11, Sept. 1932, pages 23-26. Paper presented at the Fall Meeting of the American Welding Society in Buffalo, Oct. 6, 1932. The author shows macrophotographs and photomicrographs of bare wire and heavily coated electrode arc welds, pointing out the superior qualities of the latter. The metallurgy of stress relieving is discussed. TEJ (11c)

American Tests on Welded Joints. (Amerikanische Festigkeitsversuche an Schweissverbindungen.) C. J. Hoppe. *Bauingenieur*, Vol. 13, Jan. 15, 1932, pages 48-51. Results of tests on welded joints carried out by the American Welding Society since 1926 are summarized. The deviations of results of various welders are dealt with. The minimum and mean tensile properties in welding tests that are obtained and required are considered. GN (11c)

Stress Distribution in Fillet Welds Subject to Transverse Stress. S. C. Hollister. *Journal Western Society of Engineers*, Vol. 37, June 1932, pages 168-175. This paper shows how to reduce concentrations of stresses in welds for structural connections by using a fillet with a 30° slope. It is based on extensive studies in which polarized light was projected through transparent models under stress. From the results obtained it is concluded that: (1) Excess metal in the weld in the form of rounded beads is of little advantage in the case of welds subjected to transverse shear or tension or both. (2) The critical section for elastic stress does not lie on a section through the throat perpendicular to the sloping face of the weld; but the critical section is the section forming the side of the weld which is in direct transverse shear. (3) Thorough penetration at the root of the fillet is of prime importance. Failure to achieve this penetration considerably increases the stress at this point. (4) A fillet having a 30° slope is more efficient and provides an increased length of the transverse shear plane. GTM (11c)

Strength of Electrically Welded Joints of Boilers. (Résistance des Assemblages par Cordons Frontaux et Latéraux Soudés à l'Electricité.) H. Hoehm. *Chaleur et Industrie*, Apr. 1932, pages 293-300. Results of extensive tests are expressed in formulas for each particular case. FR (11c)

Welded Steel Tube Masts. (Geschweisste Stahlrohrmaste.) A. Hilpert & J. Wanke. *Stahlbau*, Vol. 5, June 24, 1932, page 104. Discussion between Hilpert and Wanke on Wanke's paper in *Stahlbau*, Vol. 5, Jan. 8, 1932, pages 6-8. GN (11c)

Directions for Delivery and Acceptance of Additional Material for Gas and Electric Welding. (Richtlinien für Lieferung und Abnahme von Zusatzwerkstoff für Gas und Lichtbogenschweissen.) Hilpert. *Zwanglose Mitteilungen des Fachausschusses für Schweisstechnik*, No. 20, Mar. 1932, pages 2-4. The regulations for material of welding rods and electrodes with regard to quality, dimensions, supply, testing are given as they are recommended for acceptance in gas and electric welding. Also the chemical composition suitable for each type of welding is recommended. Ha (11c)

Acetylene Welding in Steel Structures. (Azetylenschweissarbeiten aus dem Stahlbau.) H. Holler. *Autogene Metallbearbeitung*, Vol. 25, Aug. 1, 1932, pages 225-232; Aug. 15, 1932, pages 242-252. Numerous examples are illustrated and their method of assembling for structural and decorative purposes explained. Certain rules are laid down for the application of fusion welding in steel structures among which should be mentioned: (1) Designer and welding engineer together must select the arrangement of the welding seams in such manner that the members can be joined without difficulty according to the ideal action of forces. (2) The designer should see, if possible, that only materials of equal thickness are joined in order to secure a uniform conduction of the heat in all directions. (3) Designer and welding engineer should determine beforehand in which sequence the welds are to be made and enter it in the drawing. This sequence must be such that the systems are closed with the final seam. (4) Other welding work should be done before welding the principal seams and the seams with the greatest welding section must be made first. (5) The welding gaps should be as small as possible. The admissible stresses for various kinds of stresses are given in the following table:

Kind of seam	Kind of stress	Admissible stress
Butt welds	tension	0.6 of admissible
	compression	0.75 " "
	bending zone of tension	0.6 " "
	zone of compression	0.75 " "
	shear	0.5 " "
Fillets	all stresses	0.5 " "

The admissible stress is that of the whole weld and can be determined from $s = P/\Sigma (a \times l)$, where P is the force to be transmitted by the seams, l the length and a the thickness of the seams. Ha (11c)

Welding in the Fence Industry. B. Heyman. *Welder*, Vol. 3, July 1932, pages 13-20. Examples of fences and gates welded together. Ha (11c)

Welding for Dynamic Stresses. C. Helsby. *Welder*, Vol. 3, July 1932, pages 10-12. The top of a pile driven into the ground by a pile driver was made very successfully of a steel tube with a head plate welded on with a "Special A" covered electrode. This top lasted longer than any other kind under a hammer of 3 tons falling 30"; 1200 blows were necessary to drive the pile in. Ha (11c)

Application of Welding to Pressure Vessels. P. R. Hawthorne. *Journal American Welding Society*, Vol. 11, Sept. 1932, pages 19-23. Paper presented at the Fall Meeting of the American Welding Society in Buffalo, Oct. 6, 1932. For certain classes of vessels, electric arc welding has entirely replaced riveting as well as all other methods of welding. The author describes welding, annealing and testing procedure for Class 1 and Class 2 welding. TEJ (11c)

The Soiling of Welding Torch Nozzles. (Das Verschmutzen der Schweissbrenner-Düsen.) M. R. Granjon. *Revue de la Soudure Autogene*, Vol. 22, No. 197, pages 2060-2062; *Die Schmelzschweissung*, Vol. 11, July 1932, page 145. If the nozzles of welding torches become dirty the uniformity and quality of the weld suffer, and the costs mount. The most effective preventions for this are: (1) Purification of the acetylene. (2) Arrangement of the burner outside of the path of the flying sparks. (3) Change of the shape of the mouth of the burner. (4) Water-cooling. (5) Burners made of rust-proof material. (6) Cr plating of the Cu burners. Ha (11c)

Advancement Made in the Welding Field. LeRoy R. Gurley. *Welding*, Vol. 3, Sept. 1932, pages 517-518, 522. A résumé of progress made in the various branches of the welding industry during the past year and some of the problems that remain for solution. TEJ (11c)

"Hartford Steam Boiler" and Fusion Welding. W. D. Halsey. *Locomotive*, Vol. 39, July 1932, pages 66-75. The welding code and test for welded vessels accepted and required by the Hartford Steam Boiler Inspection and Insurance Co. is described and classification of vessels in accordance with the code is given. Some test results are illustrated. The code was developed in conformity with the code of the A.S.M.E. Ha (11c)

Training Gas Welders for the Job. T. M. Jones. *Welding Engineer*, Vol. 17, July 1932, pages 38-39. See *Metals & Alloys*, Vol. 3, Nov. 1932, page MA 328. Ha (11c)

Welding of Electron Metal. (Die Schweissung von Elektronmetall.) H. A. Horn & K. Tewes. *Zeitschrift für Schweisstechnik*, Vol. 21, Sept. 1931, pages 201-207; Oct. 1931, pages 222-228. See *Metals & Alloys*, Vol. 3, Nov. 1932, page MA 328. EF (11c)

Trends towards Welding Construction. G. D. Fish. *Iron & Coal Trades Review*, Vol. 125, Aug. 26, 1932, page 303. **The Trend toward Welding in Construction.** Gilbert D. Fish. *Welder*, Vol. 3, July 1932, pages 22-24. General remarks on advantages and selection between riveting and welding. Ha (11c)

Performance of Welded Seams in Steel Constructions. (Ausführung von Schweissnähten an Stahlbauten.) Kommerell. *Bautechnik*, Vol. 10, Sept. 2, 1932, pages 485-486. In making heavy seams it is of extreme importance to weld with thinner rods. Tensile strength and elongation of seams should amount at least to that of the base metal. Seams welded in vertical, horizontal and inclined position and also overhead welding can be performed with good burning-in of weld metal in the root without the metal burning too deep in the side faces. Endangering of constructions on account of heat stresses due to too high welding currents is pointed out. GN (11c)

The Influence of the Various Alloying Components of the Welding Rod on the Quality of the Acetylene Welding of Structural Steels. (Der Einfluss der verschiedener Legierungsbestandteile auf die Güte der Azetylenschweissung von Baustählen.) H. Kemper. *Die Schmelzschweissung*, Vol. 11, July 1932, pages 156-158. The influence of the presence of P, S, Mn, C and Cu in the welding electrode on the tensile strength and elongation of the acetylene weld is investigated, the composition of some commercial welding wires is given. On the basis of tests it is found that C has the greatest influence on the behavior of a welded seam; wires with high C could be welded without difficulty, with increasing C the tensile strength increases in the same proportion as the elongation decreases. P and Mn exert only a slight influence, as does also S up to 0.04%; beyond this limit redbrittleness occurs. As a most suitable composition for welding of structural steels the following is recommended: C 0.15-0.25%, Mn 0.6-1.0%, P 0.05%, S 0.03-0.04%. The content of Si remaining after deoxidation should be 0.1-0.2%, a content of silica should be avoided entirely. Small additions of Ni, Cr or Mo give also excellent tensile values. The addition of Cu reduces tensile values, increasing amounts of Cu greatly reduce such values, and above 0.75% no satisfactory welds were obtained and the slag formation was so strong that welding was greatly impeded. It seems advisable not to add Cu to the wire as the new structural steels (St 52) contain about 0.5% for corrosion resistance and this small amount will not harm the weld. Ha (11c)

2

Fusion Welding of Steel Constructions. (Die autogene Schweissung im Stahlbau.) C. F. Keel. *Zeitschrift für Schweisstechnik*, Vol. 21, June 1931, pages 115-126. This article pertains to the welding of supports, columns, angle iron bases and frame connections of girders, giving 28 characteristic illustrations; the different welding possibilities, most of which are complicated, are demonstrated. EF (11c)

3

Arc Welding Tests with Structural Steel St. 52. (Lichtbogen-Schweissversuche mit Baustahl St. 52.) Küchler. *Elektroschweissung*, Vol. 3, Sept. 1932, pages 161-164. After favorable results were obtained in preliminary tests on arc welding this steel with rods containing 1.2%, 2% and 2.7% Mn (with a rod containing .85% Mn the tensile strength of the joint amounted to 85% of that of the base plate) plates 12 mm. thick, V-weld, of various straight C and alloyed St. 52 steels were welded with d.c. and wires with .65%. 1.21% and 2% Mn. The straight C steel contained .20% C, .80% Si, 1.09% Mn, .018% S, .012% P, .30% Cu. Before testing the welds were machined flush with the plate. Best results were obtained with the 1.8-2.0% Mn wires. They give welds of high tensile strength and notch toughness even when welded vertically and overhead. Practical tests substantiate the test results. GN (11c)

4

Torch-Cutting Blades of Water Turbines from Cast Steel. (Brennschneiden von Wasserturbinenschaufeln aus Stahlguss.) H. Kalpers. *Maschinenbau*, Vol. 11, June 2, 1932, page 235. Hubs and blades of 5 large water turbines were cast. Previously, the circumference of the blades had been mechanically shaped. It was decided to use oxy-acetylene torch cutting instead. This process required less time and was cheaper than machining. On account of the varying thickness of the material, the pressure of the gas had to be varied between 6 and 9 atmospheres. Cutting speed was 7.1 meters/hour. 7030 liters O_2 were needed for cutting and 500 liters O_2 and 300 liters acetylene for preheating. Mechanical devices secured a constant distance of the burner from the surface of the object. RFV (11c)

5

Joining Differently Sized Sheets by Means of the Multiple Flame Torch. (Die Verschweissung ungleich dicker Bleche mit dem Mehrflammenbrenner.) C. F. Keel. *Zeitschrift für Schweisstechnik*, Vol. 21, June 1931, pages 133-135. Detailed instructions are furnished for welding operations on differently sized sheets with the multiple flame torch with reference to the various possible seams. EF (11c)

Load Test on Welded Roof Truss. Chas. H. Jennings. *Journal American Welding Society*, Vol. 11, Sept. 1932, pages 13-18. Paper presented at the Fall Meeting of the American Welding Society in Buffalo, Oct. 6, 1932. (1) The method of designing trusses by constructing the tension members from several continuous straps which are disposed throughout the truss so as to automatically increase the cross section of the various members in proportion to the loads which they carry is sound engineering. (2) The actual stresses in the members of such a truss agree very well with the theoretical stresses computed by means of standard methods. (3) The secondary bending stresses in the various members of a truss of this design are relatively low because of the flexibility of the tension members and the joints employed. (4) Strict fabrication specifications are required to insure that all tension straps are kept straight. If they are not kept straight, an undesirable redistribution of stress may occur in some of the composite members. TEJ (11c)

Contribution to the Knowledge of the Temperature of the Oxy-Acetylene Flame and the Quality of the Weld in their Dependence on the Water Vapor Contents in the Acetylene. (Beiträge zur Kenntnis der Temperatur der Azetylen-Sauerstoff-Flamme und Güte der Schweissung in ihrer Abhängigkeit vom Wasserdampfgehalt im Azetylen.) H. Jooss. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens*. Vol. 7, 1932, pages 89-108. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 310. (11c)

7

Welding's Relations to Steel Castings. T. S. Quinn. *Industry & Welding*, Vol. 4, Aug. 1932, pages 3-6, 30-31. 3 trends of thought are discussed which have developed about welding: that it will supplant castings altogether, that castings will never be supplanted, and that there is a definite field for both welding and castings. The design of a piece should in the first place take into account which method is to be applied as only then can a satisfactory result be expected. Fusion welding has been employed advantageously in connecting steel castings to wrought steel parts. Coöperation of the foundryman with the welding engineer is urged to produce composite structures to the best economic advantage for the customer. Ha (11c)
